WENDOVER, an ancient borough and market-town in the hundred of Aylesbury, and county of Buckingham, England, is situated in Aylesbury Vale at the distance of 24 miles S.E. by S. from the county-town, and 35 miles N.W. by W. from London. It consists principally of brick houses: the inhabitants derive their chief support from lace-making; but as a branch of the Grand Junction Canal has been recently conveyed to the town, it will probably advance in importance. The earliest charter for a market at this place is dated in 1403. A subsequent charter of the year 1464 confirms the market, and grants two fairs, which are still held. This borough sent members to parliament in the 28th of Edward I., and again in the 1st and 2d of Edward II.; after which the privilege was discontinued for above three hundred years: when in the 21st of James I. Mr. Hakeville, a barrister of Lincoln's-Inn, discovered, by a search among the parliament writs in the tower, that members had been formerly sent. A petition was accordingly preferred for the restoration of the ancient franchise; and though strenuously opposed by the court, the commons decided in favour of the borough. The right of election is vested in all the housekeepers not receiving alms. The

voters are not however more than 130, most of whom occupy the burgage houses rent free. The celebrated John Hampden represented this borough in five parliaments. In the population return of the year 1811, Wendover is stated to contain 283 houses, and 1481 inhabitants. The parish-church stands a quarter of a mile from the town, but contains nothing worthy of particular notice. Near the town is a large reservoir of water, which covers about seventy acres: it was made for the supply of the canal.—*Beauties of England and Wales*, vol. i. Buckinghamshire; by J. Britton, and E. W. Brayley, 1801. *Lynson's Magna Britannia*, vol. i. Buckinghamshire, 1806.

WENFORD, a town of Sweden, in West Bothnia; 25 miles N.W. of Umea.

WENG, a town of the duchy of Stiria; 10 miles N.N.E. of Rottenmann.

WENGIA, a town of Sweden, in West Gothland; 32 miles E.N.E. of Gothenburg.

WENHAM, a township of Massachusetts, in the county of Essex, containing 554 inhabitants; 21 miles E.N.E. of Boston.

WENHOFDORF, a town of Austria; 5 miles N.W. of Schwannstatt.

WENJAN, a town of Sweden, in Dalecarlia; 44 miles W.N.W. of Fahlun.

WENIGZELL, a town of the duchy of Stiria; 11 miles W.S.W. of Fridberg.

WENINGS, a town of Germany, in the county of Isenburg; 4 miles N.W. of Birstein.

WENLOCK, GREAT, or MUCH, a borough and market-town in the hundred of Wenlock, and county of Salop, England, is situated 14 miles S.E. from Shrewsbury, and 147 miles N.W. from London. It is but poorly built, and consists of only two streets, but contains an ancient corporation, and is said to have sent members to parliament, by a writ from Edward IV. in 1478, when it sent one member; but now, jointly with Broseley and Little Wenlock, it returns two. The free burgesses, who are the electors, amount to one hundred and ten. By a charter from Charles I., the corporation consists of a bailiff, recorder, two justices of the peace, and twelve capital burgesses. The whole number of the inhabitants, by the population return of the year 1811, is enumerated as 2079, occupying 494 houses. Four annual fairs are held here; and a weekly market on Mondays. In the reign of Richard II., Wenlock was as famous for copper-mines, as it is now for quarries of limestone. The parish-church bears some marks of Norman architecture. A large round arch separates the nave from the chancel: at the west end is a square tower, with circular headed windows, from which rises a slender spire of wood, covered with lead. The interior is well fitted up: on the right of the altar are some niches; but there is no monument of sufficient antiquity or sculpture to attract the notice of the antiquary. Wenlock owes its celebrity principally to the remains of an ancient abbey, which was subsequently converted to a priory for Clugniac monks. This house was founded about the year 680, by St. Milburga, daughter of Merward, and niece of Wulphere, king of Mercia: she presided as abbess, and died about the year 716. The Danish ravagers are said to have reduced this nunnery to a state of utter desolation, in which it lay until Leofric was appointed to the earldom of Mercia. Soon after the year 1017, that earl, at the instance of his pious consort the lady Godiva, restored it; but with so little success, that, according to Malmesbury, it was found an heap of ruins, by Roger de Montgomerie, the first Norman earl of Shrewsbury, who rebuilt it in 1080, and filled it with monks from Clugni.

It is certain that none of the existing remains are older than his time; and these are confined to the chapter-house; for not a vestige is now to be traced of the pillars of the choir, which are known to have been circular, massive, and Norman. The parish-church was indeed rebuilding at, or just before the time when Malmesbury wrote (about 1127); for it was on the occasion of commencing the building of the new church, that the discovery was made of the body of St. Milburga, whose sacred relics are said to have effected many miraculous cures. The parish-church still retains evident marks of having been erected at a period consistent with this narrative: but no part of the priory, except what has been already mentioned, can lay claim to any such antiquity. The remains of the patron saint appear to have been transferred from the church of the parish to that of the priory, and perhaps some new works erected with the treasures which poured in from their fortunate discovery; for when Gervase Paganel resolved to build a priory at Dudley, which he appears to have done early in the reign of king Stephen, "he placed his deed of gift with his own hand upon the altar of St. Milburga of Wenlock, in presence of all the convent, to whose protection he committed his new foundation." Indeed the priory of St. Milburga was in such high repute for sanctity of life and strictness of discipline during this century, that in 1164 it furnished a colony of monks for the abbey of Paisley in Clydesdale. The number of monks maintained within the priory was forty, and the same appears to have been about the original number of stalls in the chapter-house: though in 1374, when an inquiry was instituted into the state of the alien priories, it was found to contain only seventeen monks. The priory was surrendered January 31. 1539-40, when a pension of 80*l. per annum* was settled upon the prior, John Cressage, and the manor-house of Madeley was assigned for his residence. The revenues of the monastery, according to Dugdale, amounted, at the time of the dissolution, to 401*l. or. 7½d.* The site was granted by Henry VIII. to one Augustino de Augustinis, who sold it, in 1545, to Thomas Lawley, esq., who made it his residence, and in whose descendants it continued, till Robert Bertie, esq., son of his great-granddaughter Urfula Lawley, by sir Robert Bertie, K.B., sold it to the family of Gage. Lord viscount Gage alienated it to sir John Wynn, bart., who devised this with his other great estates, to his kinsman sir Watkin Williams, bart., who thereupon assumed the name of the testator: he was grandfather of sir Watkin Williams Wynn, bart., the present proprietor of these venerable ruins.

Few of our English monastic remains, perhaps, are capable of affording more instruction and amusement to the lovers of ecclesiastical architecture, than those of Wenlock. The ruins are seated in a low marshy bottom, southward of the ancient borough, and adjoining the east end of the parish church-yard. The chief entrance to the monastery, from the town, was by a gate on the north side of the precinct, which appears to have been flanked with two plain square towers, one of which is standing. The most prominent features of the present buildings, are the lofty and extensive remains of the priory church, which have happily escaped the ravages of time. From these it is apparent that this sacred edifice partook of the mixed characters of the round and the pointed arch. Its magnificence fully corresponded with the opulence of the foundation, and was not surpassed by many of the stately churches of the mitred abbeys. The plan of the church was cruciform, with a central tower, but probably without towers at the west end. The extreme length was 401 feet; that of the transept 166; the nave 156; the space under the steeple 39; the choir 156;

and the chapel of the Virgin Mary 48. A fragment of the south angle of the west front is ornamented with three tiers of small arches: a window below is finished with a plain round arch. The great west window is now no more, but from the remains of one of its impostes, which is a taper-clustered pilaster, bound midway with rings, its form may be conjectured to have consisted of three lofty lancet arches. Three pointed arches on the south side of the nave are perfect, and rest on strong octagonal pillars with plain capitals. Over these commences a second division, separated by an horizontal string-course; this comprises a beautiful triforium, or open gallery, formed by lancet arches in couplets. Above these is a third compartment, from which rises a series of pointed clerestory windows, now mutilated, but evidently in the same style with the arches of the gallery beneath. A considerable fragment of the north, and the whole of the south wing of the transept are standing, both in a style coeval with the nave. The latter, a very beautiful ruin, is composed of three pointed arches on each side, resting on clustered columns, with plain but well-executed capitals. The bases of the four grand piers, which supported the steeple over the intersection of the nave, transept, and choir, may be traced nearly buried in rubbish; and evident vestiges of clustered shafts indicate that they sustained pointed arches. Of the choir, scarcely a wreck remains, yet within these few years, the lower members of six pillars, of plain and massy Norman architecture, might be discerned. Further eastward appears the foundation of the Virgin Mary's chapel, consisting of excellent masonry, with several deep basement mouldings. On the eastern side of the quadrangle was the chapter-house, a parallelogram of sixty feet by thirty, of which a very large portion is standing; and a more rare display of Norman architecture of the eleventh century can hardly be produced. The north side is almost entire. A few paces south-eastward of the chapter-house are the remains of a second quadrangle, the buildings of which, on two sides, are nearly entire. Those on the eastern side, it is presumed, belonged to the lodge of the prior, and, at the dissolution, were preserved for a mansion-house by the first lay possessors of the monastery. This consists of a long range of two stories, not very lofty, with a highly pitched and tiled roof. Along the whole front runs an elegant cloister, 100 feet in extent, composed of a series of narrow arches in couplets, with trefoil heads, and strengthened at frequent intervals with slender shelving buttresses. The eastern front of the house is adorned with ranges of rather singular windows, which have acute triangular heads, and are arranged in couplets united by very slender buttresses.—*Beauties of England and Wales*, vol. xiii. Shropshire; by R. Rylance, 1811. *Architectural Antiquities of Great Britain*, vol. iv.; by J. Britton, F.S.A. 1814.

WENLOCK, or *Winlock*, a town of Vermont; 90 miles N. of Windsor.

WENLOCK, *Little*, a town of England, in Shropshire; 8 miles N. of Much Wenlock.

WENMAN, one of the Gallipago islands, in the Pacific Ocean.

WENNE, a river of Westphalia, which runs into the Roer, 3 miles below Eversberg.

WENNEL, a river of North Wales, which runs into the Conway, near Llanrwst.

WENNER LAKE, the largest lake of Sweden, in West Gothland; nearly 90 miles long, and 40 wide. This lake is stored with great plenty of fish. Twenty-four rivers empty themselves into the Wenner lake, yet none flows out of it but the large river called Gotha Elbe, by which out-

let it discharge itself into the sea. There are several islands in this lake. In the year 1744, the diet resolved to make the passage from the Wenner lake and the Gotha Elbe to Gotheborg, and from thence to Orebro, navigable. See *CANAL of Trolhatta*.

WENERSBORG, a town of Sweden, in West Gothland, at the south-west extremity of Wenner lake. This town was once a fortress, but at present an open town. It is the staple for all the iron sent from the province of Warmeland to Gotheborg; 15 miles E. of Uddevalla. N. lat. 58° 26'. E. long. 12° 9'.

WENOOA-ETTE. See OTAKOOTAI.

WENSBECK, a river of England, which rises in Northumberland, passes by Morpeth, and runs into the German sea, N. lat. 55° 13'.

WENSYSSEL, a town of North Jutland, anciently the see of a bishop, removed to Aalborg; 18 miles N.W. of Aalborg.

WENT, a river of England, in the county of York, which runs into the Don.

WENTHUSEN, a town of Westphalia, in the bishopric of Hildesheim; 5 miles E. of Hildesheim.

WENTSCHEN, a river of Prussia, which forms a communication between lake Spirding and lake Wentfchen.—Also, a lake of Prussia; 20 miles S.E. of Bartenstein.

WENTSUM, a river of Norfolk, which runs into the Yare, below Norwich.

WENTWORTH, THOMAS, in *Biography*, Earl of Strafford, was born at London in 1593, and having finished his education at St. John's college, Cambridge, travelled abroad, and continued more than a year in France. Soon after his return he was knighted, and married the eldest daughter of Francis Clifford, earl of Cumberland. By the death of his father in 1614, he became possessed of a patrimony of 6000*l.* a year, which was considerably incumbered by a provision for seven brothers and four sisters, with the title of a baronet. Upon his entrance into public life he was nominated Custos Rotulorum of the West Riding of Yorkshire. In 1621 he was returned as a member of parliament for the county of York, and during two sessions conducted himself with circumspection and moderation. In opposition to the king's assumption of unwarrantable authority, and of his assertion that the privileges of the commons were enjoyed merely by his permission, Wentworth urged the house explicitly to declare that these privileges were their right by inheritance. In 1622 he lost his wife, and in 1625 contracted a second marriage with a daughter of Holles, earl of Clare, a young lady distinguished for beauty and accomplishments; and in this year he was returned for his county to the first parliament of Charles I. At this time he was a zealous opposer of the arbitrary measures that marked the commencement of this unfortunate reign; but as he was deemed a person of considerable importance and influence, the minister thought proper to make efforts for conciliating his attachment and support. As he was prevented from obtaining a seat in the new parliament which was convoked, by being nominated sheriff in his county, he silently submitted to this arbitrary act, and took no part in the contention that subsisted between the court and the house of commons. Buckingham, the tenure of whose power was becoming precarious, made overtures to Wentworth, and though they parted upon the best terms after a conference, he received a mandate for resigning the office of Custos Rotulorum to sir John Savile, whom he had succeeded on his dismissal. This conduct on the part of the favourite was attended with some aggravating circumstances, and very much incensed him; but he still expressed sentiments of un-

changed loyalty. Nevertheless he refused to pay his contribution to the forced loan imposed without the intervention of parliament, and for his opposition to the measure he was first imprisoned in the Marshalsea, and afterwards confined to a range of two miles round the town of Dartford. When a new parliament was summoned, in 1628, this restriction terminated, and he took his seat for Yorkshire. In this season of competition between the advocates of an arbitrary and those of a limited monarchy, Wentworth took a decided and conspicuous part with persons of the latter description, and was one of the most active promoters of the famous Petition of Right. By the measures which he then adopted and pursued, he shewed that he was worthy the purchase of the crown, nor had he virtue sufficient to withstand the temptations by which he was assailed. These were a peerage, and future promotion to the office of president of the council of York, or court of the north. He agreed to the proposed terms; and in July 1628 was created baron Wentworth, Newmarsh, and Oversey, by a patent gratifying his vanity by recognizing his claim to an alliance with the blood-royal, through Margaret, grandmother of Henry VII. Soon after he was advanced to the dignity of a viscount, admitted to the privy-council, and on the resignation of lord Scrope nominated lord-president of the north, with enlarged jurisdiction and powers, the exercise of which afterwards exceeded or directly violated the common law, and overwhelmed the country with oppression and arbitrary dominion. From this time Wentworth may be regarded as a minister and statesman, whose influence at court was in a little while freed from controul by the assassination of Buckingham, and in a popular assembly by the dissolution of parliament. Devoted to the faithful and diligent service of the crown, he obtained the confidence and support of government; and thus elevated, he manifested a haughtiness and imperiousness of temper which augmented the unpopularity resulting from a desertion of his former principles and party. Having cultivated an intimate friendship with archbishop Laud, who had succeeded Buckingham in his influence over the king's mind, he was recommended by this prelate for the direction of affairs in Ireland; the peculiar circumstances of which were thought to require the vigour and decision of Wentworth's character. Accordingly his commission as lord-deputy of Ireland was dated in 1632, though he did not remove to that country till July in the following year. The objects which he proposed in the administration of that kingdom were to render the royal authority uncontrollable, to improve the revenues, so as to render them adequate to its own expenditure, and to afford a surplus for the English treasury, and upon the whole, to derive from it every possible advantage to the monarchy. He stipulated also for the uncontrolled exercise of his own authority. Of the various measures which he pursued in his government of Ireland, our limits will not allow us to give a minute and correct detail; but for an account of these we must refer to the history of that period. His talents and industry were unquestionable, and he certainly improved the state of the country in a variety of respects; but in accomplishing some beneficial purposes he was arbitrary and tyrannical, and chargeable with severe and vindictive proceedings, which made him unpopular both there and in England; and which probably induced the king to mortify him by refusing his request of an earldom. In 1636 he visited the English court, and made a speech before the king and the committee for Irish affairs, in which he gave a minute detail of his various measures by which he had promoted the good of that kingdom and the interest of his majesty, artfully apologizing at the same time for the infirmities of

his temper. As a farther evidence of his merits with the court, he took notice of his zeal in supporting the imposition of ship-money in the exercise of his office as president of the council of York; and thus he prepared the way for renewing his petition for an earldom, which, notwithstanding his earnestness to obtain it, was again refused. Thus mortified, he refused his government with ample powers, and pursued measures similar to those which had given so great offence. His indefatigable application to business, and the irritation occasioned by the complaints and clamours of those who had reason to be dissatisfied with his conduct, subjected him to some severe paroxysms of the gout. In 1637 he advised the king not to engage in a war with Spain, and he thus incurred the lasting enmity of the queen, who wished for it, as favourable to the interest of France. In the court contest between England and Scotland, Wentworth was both an adviser and actor. After the failure of the king's first expedition against Scotland, he sent for the lord-deputy of Ireland, who arrived in November 1639. He advised the immediate renewal of hostilities, and the summoning of a parliament to provide supplies; and in order to secure his continued attachment and assistance, he obtained the earldom which he had once and again fought in vain. In January 1640 he was created earl of Strafford, decorated with the garter, and his style of lord-deputy of Ireland was changed into that of lord-lieutenant, which had been dormant from the time of the earl of Essex. Upon his return to Ireland he obtained four subsidies, and levied 8000 men for reinforcing the royal army. Afterwards the office of commander-in-chief devolved upon him; but though the Scots prevailed, and the northern counties were surrendered to the enemy, Strafford still recommended strong and arbitrary measures. His credit at court, however, was now declining, and the king was obliged by his necessities to call a parliament, which proved eventually to be the "long parliament." Strafford, perceiving his own perilous situation, requested leave to retire to his government; but the king refused to comply, and encouraged him by a solemn promise that "not a hair of his head should be touched by the parliament." The sequel shewed that Strafford's apprehensions were well-founded; for on November the 18th, 1640, Pym, in the name of the commons of England, appeared with the charge of high treason at the bar of the house of lords; and Strafford was sequestered from parliament and imprisoned. The fallen minister was now become the object of accusation in the three kingdoms; but the desertion and hatred of Ireland most deeply affected him. The articles of accusation against him were at first nine, but in the course of three months they were multiplied into twenty-eight. The principal object of his accuser was to fix upon him the charge of "having attempted to subvert the fundamental laws of the country." Against this charge he defended himself with wonderful self-possession and powers of reasoning. It became necessary, therefore, to change the original impeachment into the arbitrary mode of proceeding by a bill of attainder, in pursuing which process it was only necessary to pass an enactment of his having been guilty of high treason, and having incurred its punishment. The bill passed the house with no more than fifty-nine dissentient voices; but among these were those of some of the firmest friends of the legal liberty of their country, who thought the principles of justice shamefully violated; and in the house of lords the bill was carried more by intimidation than conviction. Hopes were still entertained from the king's promise, and his attachment to a faithful servant. But firmness was not one of the king's distinguishing virtues. His interference to stop the progress of the bill in the house

of lords had failed; and he even recurred to the plea of conscientious scruples. But his counsellors urged the danger of resisting the torrent of popular fury; the prelates, Juxon excepted, acted the part of casuists; and Strafford himself terminated the struggle by a letter, in which he persuaded the king for his own safety to ratify the bill, thus concluding it, "my consent shall more acquit you to God than all the world can do besides. To a willing man there is no injury." Love of life, however, seems to have induced him to have placed confidence in the king's promises: for when secretary Carleton informed him of his majesty's final compliance with his solicitations, he lifted up his eyes to heaven, and with his hand on his heart, exclaimed, "Put not your trust in princes, nor in the sons of men: for in them there is no salvation!" Strafford, between his condemnation and execution, employed himself in administering consolation and advice to his distressed family, and making interest for their protection. On the final day, as he was quitting the tower, he looked up to the windows of Laud's apartment, and obtaining a view of him, received his fervent blessing, which he returned with "farewell my lord! God protect your innocence!" At the scaffold he made an address to the people, expressing entire resignation to his fate, and asserting the good intention of his actions, however they might have been misrepresented; and then, taking leave of his accompanying friends, with a pathetic recollection of his widowed wife and orphan children, he calmly laid his head on the block, and giving a signal, received the single stroke that deprived him of life. He fell in the forty-ninth year of his age, lamented by some, admired perhaps by more, and leaving a memorable, though not a spotless name. The parliament, not long after his death, mitigated the sentence as far as it affected his children; and in the succeeding reign his attainder was reversed, and his heir was restored to his estate and honours." Lord Strafford was thrice married, and left an only son and several daughters. Biog. Brit. Whitelock's Mem. The Histories of the Period.

WENTWORTH, in *Geography*, a township of England, in the West Riding of Yorkshire, with about 1000 inhabitants; near it is Wentworth-House, a seat of earl Fitzwilliam; 5 miles N.W. of Rotherham.—Also, a township of New Hampshire, in the county of Grafton, containing 645 inhabitants; 3 miles S.E. of Oxford.

WENTZBURG, a town of the duchy of Warfaw; 40 miles E. of Gnesna.

WEOBLEY, an ancient borough and market-town in the hundred of Stretford, and county of Hereford, England, is situated 11 miles N.W. by N. from the city of Hereford, and 141 miles N.W. by W. from London. Anciently it formed part of the barony of the Lacies, from whom, by a female, it was conveyed in marriage to the Verdons, who, by that alliance, were for some time hereditary constables of Ireland. It afterwards passed through various families to the Devereux, earls of Essex, and formed their principal lordship. On the south side of the town stood an old castle, which was taken from the empress Maud by king Stephen. Leland mentions it as "a goodly and fine building, but somewhat in decay." Weobly sent members to all the seven parliaments of Edward I.; the privilege was afterwards discontinued till the year 1640, when it was restored by order of the house of commons. The right of voting is possessed by the owners of the ancient burghage houses, resident at the time of election, or by the inhabitants of such houses who have been resident forty days. The number of voters is about forty-five: the returning officers are the constables, in whom the government of the town is vested. The church is spacious, and

and contains some ancient monumental chapels, in which some of the Verdon family appear to have been interred. The population of the parish, as returned under the act of 1811, amounted to 626; the number of houses to 160. A small weekly market is held on Thursdays; and here are two annual fairs.—*Beauties of England and Wales*, vol. vi. Herefordshire, by J. Britton and E. W. Brayley, 1805.

WEPFER, JOHN-JAMES, in *Biography*, an eminent physician, was born in 1620 at Schaffhausen, educated at Strasburg and Basle, and after visits to several universities in Italy, took the degree of doctor at Basle, and settled in his native place. His reputation was extensive in Switzerland and Germany, and he attained, by his dissections and experiments, a high rank among those who have contributed to improve medical science. In 1658 he published a celebrated work, entitled "*Observationes Anatomicæ ex Cadaveribus eorum quos sustulit Apoplexia, cum Exercitatione de ejus loco affecto*," 8vo., often reprinted, and in some editions with the title "*Historia Apoplecticarum*." In his "*De dubiis Anatomicis Epistola*," 1664, 8vo., he asserts the entire glandular structure of the liver, prior to Malpighi. Another valuable work is entitled "*Cicutæ Aquaticæ Historia et Noxæ*," 1679, 4to.

His constitution was injured by attendance at an advanced age on the duke of Wurtemberg, and the Imperial army under his command; and he was carried off by a dropsy in 1695. His papers were published by two of his grandsons, in a work entitled "*Observationes Medico-Practicæ de affectibus Capitis internis et externis*," 1727, 4to. To the *Ephemerides Naturæ Curiosorum*, of which society he was a member, he communicated several valuable papers. Haller. Eloy.

WEPOLON, in *Zoology*, the Ceylonese name of an East Indian serpent, of a very long and slender body, and in some degree resembling a piece of cane.

WERAY, in *Geography*, a river of Wales, which runs into the Irish sea, 7 miles S. of Aberystwith.

WERBEN, a town of Brandenburg, in the Old Mark, at the conflux of the Havel and the Elbe. This town was built by Henry the Fowler, on the ruins of the ancient Castellum Vari; 33 miles N.N.W. of Brandenburg. N. lat. 52° 53'. E. long. 29° 44'.—Also, a town of Pomerania; 9 miles S.S.W. of Stargard.

WERBERG, a town of Westphalia, in the bishopric of Fulda; 12 miles S.S.E. of Fulda.

WERBKA, a town of Russian Poland, in the palatinate of Braclaw; 36 miles S. of Braclaw.

• WERD, a town of Carinthia, on a lake to which it gives name; 8 miles W. of Clagenfurt.

WERDA, a town of Saxony, in the Vogtland; 6 miles N.E. of Oelnitz.

WERDAU, a town of Saxony, in the circle of Erzgebirg; 6 miles W. of Zwickau.

WERDEL, ST., a town of France, in the department of the Sarre; 40 miles S.E. of Treves. N. lat. 49° 30'. E. long. 7° 11'.

WERDEN, a town of Germany, in the county of Mark, on the Roer; 11 miles N.E. of Dusseldorp. N. lat. 51° 18'. E. long. 6° 55'.

WERDENA, a town of Prussian Lithuania; 18 miles N.N.W. of Tilsit.

WERDENBERG, a town of Switzerland, and capital of a bailiwick, in the canton of Glarus, which was formerly governed by counts of its own, who were at one time very powerful. In the year 1485, it was purchased by the can-

ton of Lucerne; and, after changing owners, in the years 1493 and 1498, was purchased by the canton of Glarus, in the year 1519, and has remained ever since annexed to that canton, though the inhabitants have several times been mutinous and revolted. The town is fortified; 11 miles S.S.E. of Appenzell.

WERDENFELS, a town and castle of Bavaria, which gives name to a county in the bishopric of Freyung; 20 miles S. of Weilhaim.

WERDER, a town of Brandenburg, in the Middle Mark, on an island formed by the Havel; 4 miles W. of Potsdam.—Also, a district of Pomerania, between the two branches of the Vistula, about 20 miles long, and 12 in its mean breadth.

WERDING, a town of Austria; 4 miles N.N.W. of Schwannstadt.

WERDT, or WERT. See WEERT.

WERE, or WEAR, a river of England, which rises in Northumberland, crosses the county of Durham, and runs into the sea at Sunderland; anciently called "Vedra."

WERE, a river of England, which rises near Warmminster, in Wiltshire, and runs into the Avon, near Trowbridge.

WERE. See WEIR.

WERE, *Wera*, in our old *Law-Books*, signifies as much as *estimatio capitis*, or *pretium hominis*; that is, so much as was anciently paid for killing a man.

When such crimes were punished with pecuniary mulct, not death, the price was set on every man's head, according to his condition and quality. *Were suum*, id est, *pretium sue redemptionis*, his ransom.

WERELADA, among our Saxon ancestors, the denying of a homicide on oath, in order to be quit of the fine, or forfeiture, called *were*.

Where a man was slain, the price at which he was valued was to be paid to the king, and his relations: for, in the time of the Saxons, the killing of a man was not punished by death, but by a pecuniary mulct, called *wera*.

If the party denied the fact, he was to purge himself, by the oaths of several persons, according to his degree and quality. If the guilt amounted to four pounds, he was to have eighteen jurors on his father's side, and four on his mother's: if to twenty-four pounds, he was to have sixty jurors; and this was called *werelada*. *Homicidium wera solvatur, aut werelada negetur*.

WEREGILD, WEREGELD, in our *Ancient Customs*, the price of a man's head: *pretium seu valor hominis occisi, homicidii pretium*; which was paid partly to the king for the loss of his subject, partly to the lord whose vassal he was, and partly to the next of kin.

This was a custom derived to us, in common with other northern nations, from our ancestors, the ancient Germans; among whom, according to Tacitus (*De Mor. Germ. cap. 21.*), *luitur homicidium certo armentorum ac pecorum numero; recipitque satisfactionem universa domus*.

In the same manner, by the Irish brehon law, in case of murder, the brehon, or judge, compounded between the murderer and the friends of the deceased, who profecuted him, by causing the malefactor to give unto them, or to the child or wife of him that was slain, a recompence, which they called *eriach*. And thus we find in our Saxon laws, particularly those of king Athelstan, the several weregilds for homicide, established in progressive order, from the death of the ceorl, or peasant, up to that of the king himself. And in the laws of king Henry I. we have an account what other offences were then redeemable by weregild, and what were not so. The process called *appeal* had probably

its rise in the times when weregild was in use. Blackitt. Comm. vol. iv.

The weregild of an archbishop, and of an earl, was 15,000 thrimas; that of a bishop, or alderman, 8000; that of a general, or governor, 4000; that of a priest, or thane, 2000; that of a king, 30,000: half was to be paid to his kindred, and the other half to the public. The weregild of a ceorl was 266 thrimas.

WEREMOUTH, BISHOP'S, in *Geography*, a parish of England, in the county of Durham, on the river Were, with 7060 inhabitants; 12 miles N.N.E. of Durham. This parish is now incorporated in the town of Sunderland. See SUNDERLAND.

WEREMOUTH, *Monk's*, a parish of England, in the county of Durham, at the mouth of the river Were, opposite Sunderland, with 5355 inhabitants.

WEREN, a river of Wurzburg, which runs into the Maine, 6 miles below Carolstadt.

WERFEN, a town and fortress of the archbishopric of Salzburg, on the Salza, with a castle, memorable for having been the retreat of the archbishop of Salzburg, whom the duke of Bavaria had driven from his capital for having married; 15 miles N.W. of Radstadt.

WERGELA, or GUERGELA, a town of Africa, in Biledulgerid; 300 miles S. of Algiers. N. lat. $31^{\circ} 45'$. E. long. $4^{\circ} 10'$.

WERINAMA, a town on the south coast of the island of Ceram. S. lat. $3^{\circ} 15'$. E. long. $130^{\circ} 18'$.

WERING, or WORINGEN, a town of France, in the department of the Roer; 2 miles S. of Zons.

WERK. See WARK.

WERL, a town of the duchy of Westphalia; 13 miles W.S.W. of Lippstadt. N. lat. $51^{\circ} 33'$. E. long. $7^{\circ} 58'$.

WERM, or WORM, a river of France, which runs into the Roer, near Waffenberg.

WERMSDORF, a town of Saxony, in the circle of Leipzig; 36 miles N.W. of Dresden.—Also, a town of Bavaria, in the principality of Aichstatt; 4 miles N. of Aichstatt.

WERNBERG, a town of Bavaria; 3 miles N. of Pfreimbt.

WERNBURG, a town of Saxony, in the circle of Neustadt; 3 miles N.E. of Rahnis.

WERNE, a town of Germany, in the bishopric of Munster; 19 miles S. of Munster. N. lat. $51^{\circ} 38'$. E. long. $7^{\circ} 48'$.

WERNECK, a town of the duchy of Wurzburg, on the Weren; 5 miles S.W. of Schweinfurt.

WERNER, ABRAHAM GOTTLÖB, in *Biography*, a celebrated mineralogist, and professor of mineralogy at Freyburg, in Saxony, was born on the 25th of September 1750. His father was inspector of an iron-work in Upper Lusatia, and at an early period intended to educate his son for the same employment. The first scanty rudiments of his education were received at a school at Bunseur. He was afterwards sent to the Mineralogical Academy at Freyburg, and from thence to the university of Leipzig, where he applied himself to the study of natural history and jurisprudence; but the former he found more attractive, and it was here that he employed himself in defining the external characters of minerals, for which he was endowed by nature with a singular quickness of perception. At this place, he published, in 1774, his work on the external characters of minerals, which was considered as the basis of his oryctognostic or mineralogical system. (See SYSTEMS of Mineralogy.) It has been translated into various languages, but Werner

could never be persuaded to publish a new and enlarged edition. "In this work," says professor Jameson, "he gave the first example of the true method of describing mineral species. In these descriptions, all the characters presented by the *species suite* are detailed with a certain degree of minuteness, and in a determinate order; so that we have a complete picture of it, and are furnished with characters that distinguish it from all known species, and from every mineral that may hereafter be discovered." It cannot be denied, that previous to this time, the descriptive language of mineralogists had been much too indefinite to convey accurate information, or to enable mineralogists in distant countries to understand each other. Soon after this publication, Werner was invited to have the care of the cabinet of natural history at Freyburg, and to read lectures on mineralogy.

This situation, so well suited to the peculiar studies in which he was engaged, offered abundant materials for the exercise of his talent for observation and classification. In 1780 he published the first part of a translation of Cronstedt's Mineralogy. In his annotations on this work, he gave the first sketch of his mineralogical system, and published many descriptions in conformity with the methods proposed in his treatise on external characters. In this system, we find earthy minerals divided into four genera, siliceous, argillaceous, talcaceous, and calcareous; and these subdivided into species, sub-species, and kinds.

In 1791 he published a catalogue of the great mineral collection of Pabst Von Obaine, captain-general of the Saxon mines. In this work, he gave a tabular view of the whole mineralogical system, in which the arrangement of genus, species, sub-species, and kinds, is continued; several additions are made to the external characters, and the arrangement of the species is in some instances changed, owing to more extended observations. Werner, besides his lectures on mineralogy, also delivered lectures on the art of mining, which he is said to have rendered extremely intelligible by his simplification of the machinery, and by drawings and figures. His system of geognosy, or geology, was delivered in his lectures, but never published by himself. (For some account of this system, see GEOLOGY, and SYSTEMS of Geology.) "In lecturing," says a writer in the Literary Gazette of Leipzig, "he used to abandon himself (as he was accustomed to say) to his mineralogical name, and when his spirit hovered over the waters and the strata, he often became animated with lofty enthusiasm." He caused his lectures to be written out by his approved scholars, and by revising them himself made them his own in manuscript. Many parts of these lectures have been published in different countries by his pupils. Werner also published some mineralogical papers in the Miner's Journal; and in 1791 appeared his new theory of the formation of metallic veins. This work was translated into French by Daubuisson, and into English in 1809.

Werner was appointed counsellor of the mines in Saxony in 1792, and had a great share in the direction of the Mineralogical Academy, and in the administration for public works.

The cabinet of minerals collected by Werner was unrivalled for its completeness and arrangement, consisting of 100,000 specimens. This he sold for 40,000 crowns, reserving the interest of 33,000 as an annuity to himself and his sister, who had no children; and at her death, to be paid annually to the Mineralogical Academy of Freyburg.

This illustrious mineralogist died August 1817, greatly regretted by all those who were personally acquainted with him, to whom he was endeared by the simplicity of his manners,

manners, the cheerfulness and benevolence of his disposition, his integrity and disinterested devotion to science. Werner was never married. His favourite pursuit next to mineralogy appears to have been the study of antiquities, one branch of it, the numismatology of the ancients, had, during the last eight years of his life, engaged much of his attention; and he had formed a collection of 6000 Greek and Roman coins, which enabled him to make researches into the different mixtures of the metals and the arts of adulteration; and to make the subject more clear, he arranged entire series of false coins. He was also attached to the study of medicine, and had made a humorous table of diseases from infancy to old age; and among his peculiarities may be mentioned his desire of offering medical advice to his friends, and his habit of judging of his own situation, which he often thought precarious. He was greatly averse to the use of vinegar and milk, but a determined beef-eater: in other respects he lived temperately, drank but little wine, and was anxiously careful about warm-clothing and rooms, a caution not well suited to the habits of a geologist. Werner had travelled little from his own country; his visit to Paris appears to have been the only distant excursion he ever made from Saxony.

Werner may justly be said to have contributed more to extend and improve the practical knowledge of mineralogy, than any one who had preceded him. His method of observing and describing the external appearances of minerals, has been introduced by his pupils, with some modifications, into various parts of the world, and has given a new and more definite form to the science. It has indeed been objected to the method of Werner, that confining principally in the classification of minerals according to their external characters; and in the description and arrangement of these characters, it may be regarded rather as an empiric art, than a science. But in the mineral kingdom those definite characters are wanting, which serve to distinguish the genera and species in the other departments of natural history; and he who can but relieve this difficulty, and enable the student most easily to gain a knowledge of minerals under all these varying forms, is entitled to the highest praise. This palm may be pre-eminently given to Werner; and whoever has justly appreciated his labours will never stop to inquire, whether his method should rank among the sciences or the arts. Mr. Kirwan was the first who introduced a knowledge of the Wernerian mineralogy into this country; but for a more complete knowledge of it, we are indebted to professor Jameson, in his *System of Mineralogy*, first published in 1804, and in the second edition of 1817.

As a geologist, we cannot allow to Werner the same degree of unmixed praise. His system of geognosie was formed on observations made on a very limited portion of the earth's surface in his own vicinity; and he has laid down a succession of rock-formations as universally spread over the globe, because these rocks occurred in this order in a particular part of Saxony. Subsequent observations have, however, demonstrated, that even at a little distance from Freyburg, many of the supposed universal rock-formations are not to be found, and that other rocks supply their place. The reader may consult a description of the Saxon Erzgebirge by M. Bonnard, in the *Journal des Mines* for 1815, to convince himself of this. It is, we consider, fortunate for Mr. Werner's fame as a geologist, that no work of his on the subject has appeared, except the "*New Theory of Veins*." This for some time enjoyed a certain degree of celebrity from the name of the author; but the new information which it contains is very scanty, and the theory which it supports so inadequate to explain the phenomena,

and so much at variance with facts, that it was in a great part abandoned by many of the warm admirers of Werner, even some years before his death. It will now scarcely meet with a supporter among those who have any practical knowledge of mineral-veins. Mr. Werner contended for the aqueous formation of almost every kind of rock, even pumice-stone and obsidian he maintained were the products of water; and when he was repeatedly invited to visit the volcanic districts of Italy, and the ancient volcanoes of France, he declined an examination which might have greatly endangered his own theory. The followers of Werner as a geologist rest his fame not on his local observations, but on his attempt to generalize his observations, in order to form a theory which should explain the structure of the earth and the mode of its formation. Indeed such was their admiration, that they would not admit his system to be a theory, but considered it as an exposition of demonstrated facts. "This great geognost," says Mr. Jameson, "after many years of the most arduous investigations, conducted with an accuracy and acuteness of which we have few examples, discovered the manner in which the crust of the earth is constructed. Having made this great discovery he, after deep reflection, and in conformity with the strict rules of induction, drew most interesting conclusions as to the manner in which the solid mass of the earth may have been formed. It is a splendid specimen of investigation, the most perfect in its kind ever presented to the world. (Jameson's *Mineralogy*, first edition, vol. i. p. 22.) We believe there are few persons who will not now admit that the admiration and praise here bestowed were disproportioned to the object, whether we regard the merit of Mr. Werner's observations for accuracy as a geologist, or the conformity of his theory with existing appearances.

The method of investigation pursued by Werner in attempting to trace the rocks in a district in succession, from the lowest or fundamental rock to the uppermost stratum, and marking the limits of each rock where it terminates on the surface, was considered by his followers as entirely his own, and was called by them the *method of the Wernerian geognosie*. But this method had been known and practised in England long before we were acquainted with the name of Werner; indeed it is the only one which preceding geologists could practically adopt in surveying a country. On a smaller scale, it had been practised by all intelligent coal-viewers; and it had been exhibited on a larger scale by Mr. Whitehurst, in the descriptions and plates which he has given in his "*Theory of the Earth*." Sauffure followed no system; yet wherever the order of succession was apparent, he has not failed to inform us. But the country which he investigated, (Switzerland,) presents enormous masses, frequently in much apparent confusion, the order of succession being hid by debris or by glaciers. In other instances, whole mountains composed of different rocks appear to have been formed contemporaneously. Sauffure, who had no theory of any regular order of succession to support, has simply described facts as they exist. Our own countryman, William Smith, had been long employed in tracing the limits and order of succession of the strata in the midland and eastern counties of England, before the Wernerian geognosie was known either in England or Scotland.

The originality of the Wernerian geognosie consisted more in the invention of a new language adapted to support a theory, than in the discovery of a new and practical method of investigation. The language is highly objectionable in many respects, as the terms are founded on the premature assumption of the relative ages and modes of formation

of different rocks; — facts which are far from being yet clearly ascertained.

Whatever may be the defects of the Wernerian system as given us by his scholars, and however premature many of the generalizations may have been, it was of use by directing the attention of observers in various parts to an examination of its accordance with facts. Though the different rocks which Mr. Werner has described as universal formations neither occur invariably in the order of succession which he has described, nor are universally spread over the earth's surface; yet there is a certain similarity between the geological arrangement of distant countries when viewed on a large scale, which indicates that similar processes of formation had taken place, and nearly in the same order in remote parts of the globe; but we are far from knowing whether these processes were universal and simultaneous, or local and successive.

In the above observations, which it is our impartial duty as biographers to state, we have not the remotest wish to undervalue the real merits of this eminent mineralogist. His theoretical errors arose naturally from the infant state of geology when he commenced his labours; and his over-weening attachment to opinions too hastily formed, was an infirmity which he shared in common with many eminent philosophers. His errors will pass away with time, but his more useful labours will remain a durable monument of his talents and persevering research.

WERNERITE, in *Mineralogy*, a mineral regarded by Werner as a subspecies of scapolite, but which has been classed by other mineralogists as a distinct species, to which they have given this name, in honour of the professor at Freyburg. The name has been applied to foliated scapolite, compact scapolite, and to a mineral which is called Bergmannite by Stevens and Jameson. (See **SCAPOLITE**.) Wernerite occurs massive and crystallized in octohedral prisms, with four-sided pyramidal terminations. The structure is imperfectly lamellar, with joints on two directions, at right angles to each other. The colour is greenish-grey, with a pearly or resinous lustre, more or less shining; it is translucent. Wernerite is softer than felspar, yielding to the knife; its specific gravity is 3.6. It melts with intumescence into a white enamel.

This mineral is rare: it has been found at Arendal, in Norway; in the mines of Northbo and Ulrica, in Sweden; and at Campo-Longo, in Switzerland. The constituent parts are,

Silex	-	-	-	-	40
Alumine	-	-	-	-	34
Lime	-	-	-	-	16
Oxyd of iron	-	-	-	-	8
Oxyd of manganese	-	-	-	-	1.5

WERNERSDORF, in *Geography*, a town of Pomerania, on the Nogat; 7 miles S.W. of Marienburg.

WERNEUCHEN, a town of Brandenburg, in the Middle Mark; 6 miles E.S.E. of Bernau.

WERNFELS, a town of Bavaria, in the bishopric of Aichstadt; 4 miles N.W. of Spalt.

WERNHAUSEN, a town of the county of Henneberg; 4 miles N. of Wafungen.

WERNIGERODE, a county of Upper Saxony, bounded on the north by the principality of Halberstadt, on the east and south by the principality of Blankenburg, and on the west by the Harz forest; about twelve miles in length, and eight in breadth. One part is mountainous, and the other level. Amongst the mountains, the most distinguished of all is the Great Brocken, or Blockberg,

which is one of the highest; or, according to some, the very highest mountain in all Germany. On its summit scarce any small shrubs grow, much less trees; and the snow remains frequently there till midsummer, and in some of the northern parts even yet longer. The levels are very fertile in all kinds of grain, pulse, turnips, flax, culinary herbs, and other vegetables and fruits. The mountains afford very valuable plants, with berries of various kinds, particularly crown berries, of which great quantities are preserved; game and wild fowl are plentiful. In 1807, it was annexed to the new kingdom of Westphalia. The inhabitants are Lutherans.

WERNIGERODE, a town of Westphalia, and capital of a county of the same name, situated on a small river, and consisting of three parts: "The Old Town," containing two churches, and about 430 houses, with a house belonging to the county; "The New Town," containing one church, and about 200 houses; and the suburbs, called "Noschenrode," which contain one church, and 150 houses. On a high mountain, directly above the town, is the castle, in which the counts' family archives are kept. The principal business of the town consists in agriculture, brewing, distilling, and manufactures of cloth and stuffs; 12 miles S.W. of Halberstadt. N. lat. 51° 53'. E. long. 10° 52'.

WERNITZ, a river of Germany, which rises about 5 miles S. from Rotenburg, passes by Dinkelsbühl, Wassertrudingen, Oettingen, &c. and runs into the Danube, near Donauwert.

WERNSDORF, a town of Bohemia, in the circle of Saetz; 3 miles N.W. of Kadan.

WERNSTADT, a town of Bohemia, in the circle of Leitmeritz; 10 miles W. of Leypa.

WERO, an island near the coast of Norway. N. lat. 67° 43'. E. long. 9° 10'.

WERPE, a river of Germany, which joins the Sieg, near its source.

WERRA, a river of Germany, which rises in the principality of Coburg, passes by Eisfeld, Hildburghausen, Meinungen, Saltzungen, Vach, Bercka, Gerlungen, Creutzberg, Trefurt, Wanfried, Allendorf, &c. and joining the Fulda at Munden, forms the Weser.

WERRA, a department of the kingdom of Westphalia, composed of Upper Hesse, with the principality of Herfeld; with a population of 254,000 souls. Marburg is the capital.

WERREAR, a circle or district of Hindoostan, lying on the right bank of the Puddar, which separates it from Guzerat, east of Cutch.

WERSALA, a small island near the coast of Finland, at the entrance into the gulf of Bothnia. N. lat. 60° 46'. E. long. 31° 6'.

WERSÉN, a town of Germany, in the county of Tecklenburg; 8 miles N.E. of Tecklenburg.

WERSHOCK, in *Measurement*, a long measure in Russia; 16 wershocks being equal to an arsheen, or 28 English inches; so that 9 arsheens are = 7 English yards, and 4 wershocks = 7 English inches.

WERST, or **WURST**. See **VERST**.

WERT, in *Geography*. See **WEERT**.

WERTACH, a river of Bavaria, which runs into the Lech, a little below Augsburg.

WERTENSTEIN, a town of Switzerland, in the canton of Lucerne; 6 miles W. of Lucerne.

WERTER SEE, a lake of the duchy of Carinthia; 2 miles W. of Clagenfurt.

WERTH, a town of the bishopric of Ratibon; 11 miles N.W. of Straubing.

WERTHA,

WERTHA, a river of Bavaria, which runs into the Lech, near Augsburg.

WERTHEIM, a county of Germany, situated between the electorate of Mentz, and the bishopric of Wurzburg, watered by the Maine, which here receives the Tauber. The ancient counts became extinct in the year 1556. It was afterwards divided among several princes, besides several fiefs of the empire, Bohemia, Wurzburg, and Fulda.—Also, a town of Germany, and capital of a county to which it gives name, at the conflux of the Maine and Tauber. The magistrates are principally Calvinists, but the Roman Catholics and Lutherans have a church in common; 42 miles E.N.E. of Manheim. N. lat. 49° 49'. E. long. 9° 35'.—Also, a town of Germany; 22 miles E. of Frankfort on the Maine.

WERTHER, a town of Westphalia, in the county of Ravensberg; 5 miles N.N.W. of Bielefeld.

WERTINGEN, a town of Bavaria; 14 miles N.N.W. of Augsburg.

WERVICK, or WARWICK, or *Verwick*, a town of France, in the department of the Lys, on the Lys; 3 miles S.W. of Menin.

WESCHNITZ, a river of France, which runs into the Rhine, opposite Worms.

WESCHOLOUEN, a town of Prussia, in Natangen; 12 miles W. of Marggrabowa.

WESE, a river of France, which runs into the Ourt, a little above Chiny.

WESEL, a town of France, in the department of the Roer; transferred in January, 1808, from the duchy of Cleves, on the Rhine. This town was formerly imperial, and governed by its own laws, under the protection of the elector of Brandenburg; 17 miles E.S.E. of Cleves. N. lat. 51° 38'. E. long. 6° 38'.

WESEL, or *Ober Wesel*, a town of France, in the department of the Rhine and Moselle; 20 miles S. of Coblenz.

WESEL Bay, a bay on the south coast of the island of Java. S. lat. 8° 21'. E. long. 113° 42'.

WESELICH, or WEISLING, a town of France, in the department of the Roer; 7 miles S.S.E. of Cologn.

WESEN, a town of Switzerland, in the county of Gaster; 7 miles S. of Uznach.—Also, a town of Holland, in the department of Guelderland; 4 miles S. of Hattem.

WESENBERG, a town of the duchy of Mecklenburg; 42 miles N. of Spandau.

WESENSTEIN, a town of Saxony; 8 miles S.S.E. of Dresden.

WESEP, a town of Holland, on the Vecht; well fortified towards the east. The great business of the inhabitants is to carry fresh water from hence out of the Vecht to Amsterdam, for brewing and other uses, for which traffic they have a particular kind of barges; 4 miles S.E. of Amsterdam.

WESER, a river of Germany, formed by the union of the Werra and Fulda, which passes by Hameln, Rinteln, Minden, Nienburg, Hoya, Bremen, &c. and runs into the German sea, about N. lat. 53° 48'. E. long. 8°.

WESER, a department of the new kingdom of Westphalia, composed of the bishopric of Osnaburg, and part of the county of Schauenburg; the number of inhabitants is 33,400. Osnaburg is the capital.

WESLEY, JOHN, in *Biography*, one of the principal founders of Methodism, was the son of a clergyman, who, educated under a father who was ejected for nonconformity, became a zealous high-churchman, and composed the speech delivered by Sacheverel before the house of lords. John was born at Epworth, in Lincolnshire, of which his father was rector, in June 1703. Educated under pious parents,

he was religiously disposed from his youth. From the Charter-house, where he received his school-education, he was removed to Christ-church college, Oxford; and after taking his first degree, was elected, in 1724, fellow of Lincoln college, and, in 1726, proceeded to the degree of M.A. At this time he was reputed as a good classical scholar, and particularly conversant with dialectics. He was also a poet of no mean talents. Soon after his election to a fellowship, he became Greek lecturer and moderator of the classes, and undertook the instruction of pupils. In 1725 he was ordained by bishop Potter. During some years of his residence at Oxford, he was much esteemed on account of his own character and conduct, and for his attention to discipline and good morals. Upon the perusal of some devotional books, and more especially Law's "Serious Call," he became diffident as to his own religious state, and determined to pay stricter regard to what he conceived to be the essentials of a holy life. In 1729 he associated with a select number of collegians, who met and read together, first the classics on week-days, and on Sundays only divinity; but afterwards their meetings became exclusively religious. They visited the prisoners and sick poor, conversed together on the state of their minds, observed the ancient fests of the church, and communicated every week. This society, which consisted of fifteen members, attracted notice on account of the strictness of their manners and deportment; and became the objects of ridicule to some young men in the university, who denominated them Sacramentarians, the Godly club, and METHODISTS. (See the article.) Some of the seniors of the colleges were alarmed by an introduction of fanaticism; and others encouraged them to proceed, and they received the approbation of the bishop of Oxford. Wesley, after his ordination, settled as assistant to his father at Epworth, who being desirous of retaining this church preferment in his family, wished him to seek interest for obtaining it; but his attachment to Oxford, and to the society which had been there formed, prevailed over every other consideration. In process of time he formed a purpose of going to Georgia, as a missionary; and accordingly he embarked for this province in the year 1735. The prospect of success in this mission seemed at first to be favourable; but several circumstances occurred which changed his views, and induced him to leave Georgia, after a residence of one year and nine months. These circumstances, as some persons have related them, reflect no great honour on Wesley's disposition and character. It appears, however, upon the whole, more especially when we consider Whitefield's success in the same part of the world, that he was less qualified for a missionary than his fellow-labourer. After his return to England, he felt dissatisfied about his own state, and entertained suspicions of the reality of his own conversion, though he had undertaken to convert others. Prepared for a sudden conversion, it actually happened at a place and time, and in a manner, which he has recorded. According to his own account, this memorable event is referred to the 24th day of May, in the year 1738, at a quarter before nine in the evening, when some person at a society in Aldersgate-street was reading Luther's preface to the epistle to the Romans. "He felt his heart strangely warmed. He felt that he trusted in Christ alone for salvation; and an assurance was given to him, that Christ had taken away his sins, and saved him from the law of sin and death." These feelings of assurance, however, were blended with occasional misgivings; and it seems that, in his case, enthusiasm could not instantaneously overpower his philosophical reasonings. His case is far from being singular in the history of persons of the same description. About this

time he took a journey to Germany, in order to derive a further confirmation of his faith from intercourse with congenial spirits at the head-quarters of the Moravians, at Herrnhuth. (See *UNITAS Fratrum*.) After his return to England, in September 1738, he entered on his course of labours; and preached or exhorted, frequently three or four times a day, in prisons and other places of the metropolis, as well as in various parts of the country, where the fervour of his zeal bore proportion to the degree of obloquy which he incurred. His discourses produced wonderful effects, and occasioned in the hearers swoonings, exclamations, convulsions, &c. which have been often the accompaniments of violent emotions. At Bristol, where he had been preceded by Whitfield, he collected large crowds of attendants in the open air. But it was now desirable that a building should be erected for the accommodation of the followers of these popular preachers. In May 1739, the first stone of such an edifice was laid at Bristol; and with this building commenced the absolute and unlimited power which Wesley exercised over his followers. "The direction of the work was first committed to eleven feoffees of his nomination; but as it became necessary for him to engage for the payment of the workmen, and to collect money for this purpose, he visited London, and upon consulting Whitfield and others, he was told, that they would do nothing in the matter, unless he would discharge the feoffees, and take the whole business into his own hands. They gave various reasons for this determination; but one," says Wesley, "was enough, *viz.* that such feoffees would always have it in their power to controul me; and if I preached not as they liked, turn me out of the room that I had built." He, therefore, assembled the feoffees, and with their consent cancelled the instruments made before, and took the whole management into his own hands; and this precedent he ever after followed, so that all the numerous meetings of his classes of Methodists were either vested in him, or in trustees who were bound to give admission into the pulpit either to him, or to such preachers as he shall appoint. Unable to associate clergymen in the prosecution of his plan, which seems to have been his first design, he determined to employ lay-preachers as itinerants to the different societies; and of their talents he formed some judgment by their performances at the meetings for prayer and mere private exhortation. Reserving to himself the nomination of his preachers, his authority was extended as his societies were multiplied. For the use of these societies, he and his brother Charles drew up a set of rules for the direction of their moral and religious conduct, which are said to have been formed upon the purest model of primitive Christianity. A circumstance occurred which threatened injury to the cause of Methodism; but it eventually contributed to its extension, and to the establishment of Wesley without a rival at the head of his own body. Whitfield had imbibed a predilection for the doctrines of the Puritan divines, which were in general Calvinistic. Wesley's opinions were Arminian; so that it was impossible for these two leaders of separate tenets to unite. "The differences between them turned upon the three points, unconditional election, irresistible grace, and final perseverance, concerning which topics their notions varied so much, that Whitfield plainly told his brother reformer, that they preached two different gospels, and that he would not only refuse to give him the right hand of fellowship, but was resolved publicly to preach against him and his brother wheresoever he preached at all." Although they afterwards spoke of each other with esteem, yet their separation was entire and lasting.

The system of discipline formed by Wesley was admirably

contrived both for gaining profelytes, and for extending and making permanent his own influence. As he did not profess to establish a new or distinct sect, he did not interfere with the regular worship either of the establishment or of Dissenters, so that he and his preachers robbed no other ministers of their hearers; and they availed themselves of those seasons, which gave persons that were desirous of attending leisure for this purpose. That he might not be charged with drawing people away from the established church, or other societies of Christians, he did not administer the sacrament of the Lord's Supper in his own chapels, but recommended attendance for this purpose in the established church. (See *METHODISTS*.) The plan of itinerancy was a political measure in the system of Mr. Wesley, as variety serves to excite curiosity, and to increase the number of his followers. It seems also to relieve preachers and hearers, when the flock of the former is small; and it also prevents these missionaries, if they may be so called, from forming permanent connections in any place whither they are sent, and of acquiring an influence, which would be inconsistent with the supremacy of the chief. In order to maintain an union between the members of this body, and to exercise a degree of vigilant inspection with regard to their conduct, Wesley has divided each society into companies of ten or fifteen, called classes, to each of which belongs a leader, whose business it was every week to see every person of his class, and to inquire into his religious state. Many of these companies were divided into smaller parties, called bands, in which the married and single men, and the married and single women, were ranged apart, and they were directed to maintain a confidential intercourse with regard to their character and state with each other. From these bands again were formed select bands, consisting of those who had attained to perfection. Of his love-feasts, &c. we have given an account under *METHODISTS*. Stewards were appointed to receive contributions, which the lowest members were expected to pay, however small the sums, and to superintend the temporal concerns of the societies. In order to preserve a connection between the preachers, as well as to maintain their ultimate subordination to him, Wesley found it useful to summon annually a considerable body of them, in order to take counsel with him, and with one another, concerning the general affairs of the societies. These assemblies were called "Conferences;" and the great number of them at which Wesley had to preside was a principal means of consolidating the whole frame of the society, and maintaining his permanent authority over every part. Wesley and his first followers had many difficulties with which to contend; but their constancy and fortitude, and the apparently beneficial effects of their endeavours in reforming some of the most abandoned members of the community, enabled them ultimately to triumph over all opposition, and to pursue their labours without molestation. On account of his fanaticism and enthusiasm he has suffered ridicule and reproach; and some have even suspected his sincerity in the details which he has given of the extraordinary manifestations of light that have been communicated to him, and the no less extraordinary interpositions of Providence in his favour; alleging that he possessed a degree of understanding which could not be deluded, and, therefore, charging him with a design of deluding others, in order to serve his own purposes. But these are harsh reflections, the justice of which we cannot be induced easily to allow. About the year 1759, Wesley, who had long been the eulogist of a single life, thought proper to marry a rich widow, whose fortune he settled wholly upon herself; but this connection proved an occasion of infelicity,

felicity, and therefore they separated. She died in 1781. Wesley seems to have adopted his father's high-church principles, and he persevered in avowing his connection with the established church, and in preventing, as far as possible, a separation between his followers and the professors of the established religion. During the American war he was a zealous advocate for the measures of government, and he inculcated the duty of submission to the trans-Atlantic Methodists. With this view he published a pamphlet, entitled "A Calm Address to the American Colonies," which was widely disseminated; and though some of his followers were displeased, others were supporters of the authority of Great Britain; whilst, on the other hand, the Methodists in the connection of Mr. Whitefield were generally on the side of American independence. When the contest terminated, it became a matter of some importance to determine what kind of connection should subsist between the American Methodists and their British brethren. Mr. Wesley was induced for this purpose to take a step, which appeared to be a renunciation of the principle of an episcopal church. By his own authority he ordained, with imposition of hands, several preachers who were embarking for America, and consecrated a bishop for the Methodist episcopal church in that country, who, on his arrival, consecrated another, and ordained several as presbyters. He also assumed the same authority with respect to Scotland; "Setting apart," as he says, "three preachers in 1785 to administer in that country the sacraments of baptism and the Lord's supper." In self-defence he alleged, that he had been for several years convinced by lord King's account of the primitive church, that bishops and presbyters are the same order, and have the same right to ordain; but that he declined exercising this right in ordaining his travelling preachers, because he did not wish to violate the established order of the national church to which he belonged. By these measures he offended many in his own connection, and particularly his brother Charles; and it is said, that before his death he repented of his proceedings, and used all his endeavours to counteract the tendency which he then perceived to a final separation from the church.

In a very advanced age, Wesley retained his ability of bearing the fatigue which attended his numerous and extensive labours; and these were continued till within a week of his death, which happened on March 2d, 1791, in the 88th year of his age.

In Wesley's countenance mildness and cheerfulness were blended with gravity, and in old age it was singularly venerable. "In his manners," says one of his biographers, "he was social, polite, conversible, and pleasant, without any of the gloom and austerity common in the leader of a sect. In the pulpit he was usually short and clear, argumentative and sedate, often entertaining, but never attempting the eloquence of the passions. His style in writing was of a similar cast; he expressed himself with facility and precision, and even in controversy seldom elevated his tone beyond a temperate medium. He was placable towards his enemies, charitable, and in pecuniary matters extremely disinterested. His greatest failing was a love of power, which rendered him impatient of contradiction with regard to every thing that concerned his administration as head of his society; yet it is certain that he could not have brought his plans to effect, without a considerable share of absolute authority. It must also be admitted, that he had much of the politician in his character, and could employ artifice when useful for his purposes. That he was thoroughly persuaded of the truth of the system he taught, and had at heart the best interests of mankind, it would be uncandid and unwarrantable

to question; and he will be a memorable person as long as the fabric which he so much contributed to raise shall endure." Lives of J. Wesley, by Hampson, Coke, and Whitehead. Gen. Biog. See METHODISTS.

WESLINGBUHREN, in *Geography*, a town and duchy of Holstein, situated near the coast of the North sea; 53 miles N.W. of Hamburg.

WESOWKA, a town of Poland, in Volhynia; 60 miles N.N.E. of Zytomiers.

WESSEL, JOHN, in *Biography*, an eminent philosopher and divine, was born at Groningen about the year 1409, or 1419; and pursued his studies with incredible ardour both at Zwoll and at Cologne. At the latter place his orthodoxy was suspected, as he proposed difficulties which his masters could not solve. He taught philosophy for some time at Heidelberg, and after visiting several universities, went to Paris, where the disputes ran high between the Realists, Formalists, and Nominalists. He fluctuated between the opinions of these different sects. He predicted the decline of the doctrines of Thomas Aquinas, Bonaventure, and other disputants of that class; and intimated his apprehension that they would be exploded by all true Christian divines, and that the irrefragable doctors themselves would be little regarded. His reputation procured for him the esteem of Francis delle Rovere, general of the Friars Minors, whom he accompanied to the court of Basil, and with whom he returned to Paris, where he resided many years. When his patron was made pope, under the name of Sixtus IV., he paid him a visit at Rome, and being told that his holiness would grant him whatsoever he asked, he limited his request to a Hebrew and a Greek bible from the Vatican. "You shall have them," said the pontiff; "but, simple man that you are! why did not you ask a bishopric?" "Because (answered Wessel) I do not want one;" a reply on which Dr. Jortin has bestowed just applause.

This worthy person died at Groningen in 1489. On his death-bed he lamented to a friend that he had been distressed with doubts concerning the truth of the Christian religion; but at his friend's second visit, he told him with great satisfaction that his doubts were all dissipated. So extraordinary was his learning, that he was distinguished by the appellation of the "Light of the World;" and such was his spirit of free enquiry, that his name is enrolled in the Protestant Catalogue of Witnesses of the Truth. Of his liberal opinions some were, "that the pope might err—that erring he ought to be resisted—that his commands are obligatory only as far as they are conformable to the word of God—and that his excommunications are less to be feared than the disapprobation of the lowest worthy and learned man." We need not wonder then that the monks should have committed all the manuscripts found in his study to the flames. Such as escaped conflagration were printed collectively at Groningen in 1614, and at Amsterdam in 1617. Part of them had been previously printed at Leipzig in 1522, under the title of "Farrago Rerum Theologicarum," with a preface by Martin Luther. Bayle. Mosheim. Brucker by Enfield.

WESSELY, in *Geography*, a town of Moravia, in the circle of Hradisch; 5 miles N.N.E. of Strasnitz.—Also, a town of Bohemia, in the circle of Bechin; 5 miles S. of Sobieslaw.—Also, a town of Moravia, in the circle of Brunn; 36 miles N.W. of Brunn.

WESSEM, or WESSUM, a town of France, in the department of the Lower Meuse; 4 miles S.S.W. of Ruremond.

WESSEN, a town of Austria; 9 miles N.W. of Efferding.

WESSNITZ. See WEISSENITZ.

WEST, GILBERT, in *Biography*, the son of the Rev. Dr. West, prebendary of Winchester, and of a sister of sir Richard Temple, afterwards lord Cobham, was born in 1706, and educated for the church at Eton and Christchurch, in Oxford; but preferring a military life, he served in the army till he received an appointment in the office of lord Townshend, secretary of state, with whom he accompanied king George I. to Hanover. In early life he entertained doubts concerning the Christian religion, which were instilled into him and his cousin Lyttelton by lord Cobham. In 1729 he was appointed a clerk-extraordinary of the privy council; and soon after, being married, he settled at Wickham in Kent. His income was not large, but it was sufficient to entertain his friends Pitt and Lyttelton, who often visited him for literary recreation at Wickham. As a poet, he was known in 1742 by a piece on a dramatic plan, intitled "The Institution of the Order of the Garter," distinguished by pure and elevated morality, and containing passages of elegant fancy and splendid diction. West's "Observations on the Resurrection of Christ," published in 1747, engaged the particular attention of the public, and even induced the university of Oxford to confer upon the author the degree of doctor of laws. This work was so well executed, that we may well regret his not having lived to have completed his design by another work on the evidence of the truth of the New Testament. In 1752 the circumstances of our author were improved by succeeding, when Mr. Pitt became paymaster-general, to one of the lucrative clerkships of the privy council, and his obtaining the place of treasurer to Chelsea hospital. In 1755 he lost an only son, and in the following year his life was terminated by a paralytic stroke, March 1756, at the age of fifty. "Mr. West was a gentleman in manners, agreeable in conversation, and lively though serious. He was regular in the performance of family devotion and in attendance on public worship, and was particularly attached to Dr. Clarke as a preacher."

The other works of Mr. West were, "Translations of the Odes of Pindar, with a Dissertation on the Olympic Games;" "Translations from the Argonautics of Apollonius Rhodius, and the Tragopodagra of Lucian;" "The Abuse of Travelling;" and "Education:" poems in the imitation of the stanza and manner of Spenser; "Iphigenia in Tauris," from Euripides;" and "Original Poems on Various Occasions." Several of these pieces were printed in the collections of Doddsley and Pearch, and also in three distinct volumes, 12mo. 1766; and entitle the author, says his biographer, to a respectable rank among the minor poets. Johnson's Lives. Nichols's Lit. Anecd. Gen. Biog.

WEST, *Occidens, Occafus*, in *Cosmography*, one of the cardinal points of the horizon; diametrically opposite to the east.

West is strictly defined, the intersection of the prime vertical with the horizon, on that side in which the sun sets.

To draw a true west line, see MERIDIAN.

WEST, in *Astronomy*, is chiefly used for the place, in or towards which the sun and stars sink under the horizon. Thus we say, the Sun, Mars, &c. are in the west.

The point in which the sun sets when in the equator, is particularly called the *equinoctial west*, or *point of true west*.

WEST, and *Western*, in *Geography*, are applied to certain countries, &c. situated towards the point of sun-setting with respect to certain others.

Thus, the empire of Rome, anciently, and of Germany, at present, is called the *empire of the West*, or *western empire*, in opposition to that of Constantinople, which is called the *empire of the East*.

The Latin or Roman church is called the *western church*; in opposition to the Greek church.

The French, Spaniards, Italians, &c. are called *western nations*, in respect to the Asiatics; and America, the *West Indies*, in respect of the East Indies.

WEST-*Astion Water*, is a chalybeate water, resembling that of Holt. See Phil. Transf. N^o 461. sect. 20.

WEST *Wind* is also called *Zephyrus*, and *Favonius*. See WIND.

WEST *Saxonlage*, or the law of the West Saxons. See LAW.

WEST *India Companies*. See COMPANY, &c.

WEST *Dial*. See DIAL.

WEST, *Mooring for*. See MOORING.

WEST, in *Geography*, a township of Pennsylvania, in the county of Huntingdon, with 1698 inhabitants.

WEST *Bay*, a bay of the South Pacific ocean, in Cook's Straits, between the two islands of New Zealand.

WEST *Bay*, a bay of the English Channel, on the coast of the counties of Dorset and Devon, of vast extent. It begins west of Portland, and ends at Berry Point near Torbay, according to some; according to others, from Portland to Lyme or Exmouth. The tide is current here nine hours; high water at ten o'clock at new and full moon; an E.S.E. moon makes full sea. The sea off the coast is reckoned the most dangerous part of the Channel, especially on the west, where ships, not aware of the currents, are embayed and driven ashore on the beach. When ships are so deeply embayed, that there is no possibility of getting off, especially at the beginning of the ebb, they may run boldly on the beach, and the mariners are to remain aboard for five or six seas, but may then step on shore with safety; but if they leave the ship instantly it is dangerous and fatal: light-houses have been serviceable for preventing these accidents. Where ships that come from the west neglect to keep a good offing, or are taken short by contrary winds, and cannot weather the highland at Portland, but are driven between the island and the main-land, they perish without remedy; and it has been observed, that more Dutch vessels are lost here than any other, almost every year, especially in winter, which is thought to be owing to an obstinate adherence to old charts, and not allowing for the true variation of the compass. When the variation is W. the true channel course is W. by S. from Dungeness to the Caskets; Portland Bill and the Caskets are 15 leagues asunder nearly in a meridian. Dr. Halley observes, that the navigation up and down the Channel is an E. variation: W.S.W. is the true course. The Channel between Portland and the Caskets is 40 fathoms deep, and in fair weather one may see in that depth the land on both sides: the nearer England the shoalier, the nearer the Caskets the deeper.

WEST *Bay*, a bay at the western extremity of lake Superior. N. lat. 46° 45'. W. long. 91° 45'.—Also, a bay on the N.W. coast of Virgin-Gorda, in the West Indies. N. lat. 18° 23'. W. long. 62° 48'.

WEST *Bethlehem*, a township of Pennsylvania, in the county of Washington, containing 1849 inhabitants.

WEST *Boylston*, a town of Massachusetts, in the county of Worcester, containing 632 inhabitants.

WEST *Bradford*, a township of Pennsylvania, in the county of Chester, with 1219 inhabitants.

WEST *Buffaloe*, a township of Pennsylvania, in the county of Northumberland, containing 2523 inhabitants.

WEST *Calh*, a township of Pennsylvania, in the county of Chester, with 1003 inhabitants.

WEST *Cambridge*, a town of Massachusetts, in the county of Middlesex, containing 971 inhabitants.

WEST Cape, a cape on the W. coast of Tavai-poe-nam-moo, the southernmost island of New Zealand. S. lat. 45° 54'. W. long. 193° 17'.

WEST Cappel, a town of Holland, in the island of Walcheren; 6 miles N.W. of Middleburg.

WEST Chester, a county of New York, containing 30,272 inhabitants.

The following statistical table is founded upon the census of 1810.

Towns.	Population.	Sen. Electors.
Bedford - - -	2,374	241
Cortlandt - - -	3,054	182
East-Chester - - -	1,039	96
Greensburgh - - -	1,862	137

	<u>30,272</u>	<u>2,318</u>

It sends three members to the house of assembly. It is situated on the E. side of the Hudson, N. of New York county; bounded N. by Dutchess county, E. by the state of Connecticut, S. by Long island sound and East river, W. by Haerlem river and the Hudson; or by New York county, the state of New Jersey, and the county of Rockland. Its area is about 480 square miles, or 307,200 acres, situated between 40° 47' and 41° 22' N. lat.; 3° and 32' E. long. from New York.

WEST Chester, a post-township of New York, at the S.W. extremity of West Chester county, on East river; 12 miles from New York. Its medial extent from N. to S. may be 4 miles, and from E. to W. about 5, with an area of 20 square miles. It is a valuable tract of land, somewhat stony, with a large proportion of clayey loam, which, with good husbandry, may be rendered productive. West Chester village, situated at the head of the navigation on West Chester creek, contains about 25 dwellings, an episcopal church, a Friends' meeting-house, a school-house, a grist-mill, and about 200 inhabitants. Adjoining to it are a bed of marble and an extensive common. In the township are several manufactories, grist-mills, three houses for worship, one for Friends, one for Episcopals, and one for Dutch Lutherans, and six school-houses, and many elegant country-seats. For its population, &c. see the preceding article.

WEST Chester Borough, a township of Pennsylvania, in the county of Chester, containing 471 inhabitants.

WEST Creek, a river of New Jersey, which runs into the Delaware bay, N. lat. 39° 14'. W. long. 74° 57'.

WEST Fallowfield, a township of Pennsylvania, in the county of Chester, containing 1157 inhabitants.

WEST Gothland, or *Westrogothia*. See **GOTHLAND**.

WEST Harbour, a bay on the S. coast of Jamaica, formed

by a peninsula, called Portland Ridge. N. lat. 17° 48'. W. long. 77°.

WEST Indies, in *Geography* and *Commerce*, comprehends all the islands that lie in the Caribbean sea, between North and South America; and also a few of the neighbouring settlements on the continent. (See *WEST INDIES*.) The larger islands, or greater Antilles, are, Jamaica, belonging to the English, Cuba (Spanish), Porto Rico (Spanish), and St. Domingo (French and Spanish). The smaller islands, or lesser Antilles, called also the Caribbee islands, are divided into *leeward* and *windward* islands. The former are Tortola, the Saints, Barbuda, Antigua, St. Kitt's, Nevis, Montserrat, and Dominica (English), Guadaloupe and Marigalante (French), St. Eustatia and Martin (Dutch), St. Thomas, Santa Cruz, and St. John (Danish), and St. Bartholomew (Swedish). The latter are, Barbadoes, St. Vincent, Grenada, and Tobago (English), Martinico and St. Lucia (French). The islands on the coast of Terra Firma are, Trinidad and Margarita (Spanish), Curassoa and Bonaire (Dutch). The settlements on the continent of South America are, Demerara, Berbice, Essequibo, and Surinam (Dutch). In specifying the monies, coins, currencies, and exchanges of the West Indies, we shall avail ourselves of the arrangement of Dr. Kelly in his valuable work, and class the islands under the five general heads of English, French, Danish, Dutch, and Spanish; premising, that though the several islands and settlements, which we have already enumerated, are subject to various political changes, they nevertheless, for the most part, retain the weights, measures, and denominations of money belonging to the European nations by which they have been colonized.

In the *English* islands, accounts are kept in pounds, shillings, and pence currency; the West India currency being an imaginary money, which varies considerably in its proportion to sterling, so that it is in some places reckoned at 140, and in others 200, for 100*l.* English, more or less. The principal coin circulating in the West Indies is the Spanish dollar, and this seems to be the standard by which the value of all other monies is regulated; and with regard to the proportion between sterling and currency, it should be observed, that although it has been declared by different authorities, yet it is chiefly regulated by the course of exchange with London. Of the *English* islands, the first we shall take notice of is Jamaica. The currency of this island is 140*l.*, and its proportion to sterling is as 7 to 5; so that 1*l.* sterling is = 28*s.* currency, and 1*l.* currency = 14*s.* 3½*d.* sterling. The price of the dollar is 6*s.* 8*d.* currency.

The gold coins current in this island, with their value in currency, appear in the following Table.

		dwt. gr.	Jamaica Currency.		
			<i>l.</i>	<i>s.</i>	<i>d.</i>
Spanish	Doubloon - - -	17 8	5	0	0
	Two pistole piece - - -	8 16	2	10	0
	Pistole - - -	4 8	1	5	0
Portuguese	Half pistole - - -	2 4	0	12	6
	Johanes (called joe) - - -	18 12	5	10	0
	Half joe - - -	9 6	2	15	0
	Quarter joe - - -	4 15	1	7	6
English	Moidore - - -	6 22	2	0	0
	Half moidore - - -	3 11	1	0	0
	Guinea - - -	5 8	1	12	6
	Half guinea - - -	2 16	0	16	3
	Seven-shilling piece - - -	1 19	0	10	10

WEST INDIES.

The deduction for every grain of deficiency of weight is 3d. currency.

The silver coins of Jamaica are dollars, with their halves, quarters, eighths, and sixteenths, passing for 6s. 8d., 3s. 4d., 1s. 8d., 10d., and 5d. currency. Besides, here are *bits* or *bits*, being Spanish reals, and passing for 7½d. currency; so that 10 bits and 5d. currency make a dollar, and 1 bit is worth 5¼d. sterling. *Pistereens*, or two-bit pieces, which are Spanish pecetas, pass for 1s. 3d. currency, and are worth 10¾d. sterling. English shillings and sixpences occasionally pass as pistereens and bits. From the above statement it appears, that the intrinsic par of the currency of Jamaica with respect to sterling is as follows; the calculations being made according to the mint price of gold and silver in England:

According to the	<table style="border-collapse: collapse; border-left: none;"> <tr> <td style="padding: 2px 10px;">English gold coins, 100l. sterling =</td> <td style="padding: 2px 10px;">154 15 0</td> <td rowspan="4" style="font-size: 2em; vertical-align: middle; padding: 0 10px;">}</td> <td rowspan="4" style="vertical-align: middle;">currency.</td> </tr> <tr> <td style="padding: 2px 10px;">Spanish ditto - - - -</td> <td style="padding: 2px 10px;">156 13 2</td> </tr> <tr> <td style="padding: 2px 10px;">Portuguese ditto - - - -</td> <td style="padding: 2px 10px;">155 0 0</td> </tr> <tr> <td style="padding: 2px 10px;">Dollar - - - - -</td> <td style="padding: 2px 10px;">154 11 9</td> </tr> </table>	English gold coins, 100l. sterling =	154 15 0	}	currency.	Spanish ditto - - - -	156 13 2	Portuguese ditto - - - -	155 0 0	Dollar - - - - -	154 11 9
English gold coins, 100l. sterling =	154 15 0	}	currency.								
Spanish ditto - - - -	156 13 2										
Portuguese ditto - - - -	155 0 0										
Dollar - - - - -	154 11 9										

By a law of the Jamaica assembly, the exchange with England was fixed at 40 per cent.; but it has considerably varied: bills being sometimes at a premium of 20 per cent. above the legal exchange, and seldom under 10: dollars occasionally bear a premium of 3 or 4 per cent.

The currency of *Barbadoes* is sometimes reckoned at 135, and sometimes at 140, for 100l. sterling; but it has never been settled by legal authority. The value of the coins has been established by proclamation, and according to these values the par is above 140.

The gold coins current here, with their legal value, are shewn in the following Table.

			Barbadoes Currency.		
			dwt.	gr.	l. s. d.
Spanish	Doubleloon	- -	17	8	4 10 0
	Two-pistole piece	- -	8	16	2 5 0
	Pistole	- -	4	8	1 2 6
Portuguese	Half pistole	- -	2	4	0 11 3
	Johanes (called joe)	- -	18	10	5 0 0
	Half joe	- -	9	5	2 10 0
	Quarter joe	- -	4	14	1 5 0
English	Moidore	- -	6	21	1 17 6
	Half moidore	- -	3	10	0 18 9
	Guinea	- -	5	8	1 10 0
	Half guinea	- -	2	16	0 15 0
	Seven-shilling piece	- -	1	19	0 10 0

N.B.—The deduction for light coin is 2¾d. currency for every grain of deficiency.

The current silver coins are dollars, with halves, quarters, eighths, and sixteenths, passing for 6s. 3d., 3s. 1½d., 1s. 6½d., 9½d., and 4¾d. currency. Also bits, which are Spanish reals, and which pass for 7½d. currency; thus, 10 bits make 1 dollar, and 1 bit is worth 5¼d. sterling. *Pistereens*, or two-bit pieces, which are Spanish pecetas, pass for 1s. 3d. currency. There are also French bits, called *crimbal*, or *isle du vent bits*, which pass for 7½d. currency.

The Barbadoes currency compared with sterling is,

According to the	<table style="border-collapse: collapse; border-left: none;"> <tr> <td style="padding: 2px 10px;">English coins, 100l. sterling =</td> <td style="padding: 2px 10px;">142 17 2</td> <td rowspan="4" style="font-size: 2em; vertical-align: middle; padding: 0 10px;">}</td> <td rowspan="4" style="vertical-align: middle;">currency.</td> </tr> <tr> <td style="padding: 2px 10px;">Spanish ditto - - - -</td> <td style="padding: 2px 10px;">141 0 0</td> </tr> <tr> <td style="padding: 2px 10px;">Portuguese ditto - - - -</td> <td style="padding: 2px 10px;">140 13 7</td> </tr> <tr> <td style="padding: 2px 10px;">Dollar ditto - - - - -</td> <td style="padding: 2px 10px;">144 19 6</td> </tr> </table>	English coins, 100l. sterling =	142 17 2	}	currency. Spanish ditto - - - -	141 0 0										
Portuguese ditto - - - -	140 13 7										
Dollar ditto - - - - -	144 19 6										

In the English leeward islands the dollar is reckoned at 9s., and this rate is generally called the leeward currency.

A small circular piece cut out of the centre of the dollar, about one-twelfth of its value, in order to prevent its exportation, is allowed to pass for one-eighth, and is stamped by authority with the initials of the island.

The dollar, thus cut, passes for 8s. 3d. currency; it is called the "cut dollar," by way of distinction from the whole or "round dollar." The piece taken out is sometimes called the "bit," and sometimes the "moco," which moco is, in some places, one-fourth of the dollar, and in others one-eighth. In these islands there are small copper coins, called *stamps*, *dogs*, and *half dogs*, valued as in the following Table.

		Leeward Currency.		
		l.	s.	d.
2 Half dogs	- make 1 Dog	=	0	0 1½
1½ Dog	- - - 1 Stampe	=	0	0 2¼
6 Dogs or 4 stamps	- 1 Bit	=	0	0 9
1½ Bit	- - - 1 Moco	=	0	1 1½
11 Bits	- - - 1 Cut dollar	=	0	8 3
12 Bits or 8 mocos	- 1 Round dollar	=	0	9 0
5 Round dollars	- 1 Guinea	=	2	5 0
8 Cut dollars	- 1 Joe	=	3	6 0
16 Round dollars	- 1 Doubleloon	=	7	4 0

For a deficiency of weight, an allowance is made of 4¾d. currency for English grain. The exchange with London is generally about 200 per cent.

In the English windward islands the currencies are nearly the same as the former, allowing for some local regulations and customs.

In the French islands accounts are kept by the French settlers in livres, sols, and deniers; and by the English (particularly in exchanges) in pounds, shillings, and pence currency; the livre and shilling being of the same value.

The currency is the same as that of the English leeward and windward islands: but the names of the coins are different; the dog being called the *noir*, the *stampe* the *tempé*, the bit the *escalin*, and the dollar the *gourde*.

The value of the coins appears in the following Table.

		Leeward Currency.		
		liv. sol. den.	l.	s. d.
The noir, or dog	- - -	0 2 6	0 0	1½
The tempé, or stamp	- - -	0 3 9	0 0	2¼
The trois tempés	- - -	0 11 3	0 0	6¾
The escalin, or bit	- - -	0 15 0	0 0	9
The trois petites pieces	- - -	1 2 6	0 1	1½
The piece de trente sols, or pistereen	- - -	1 10 0	0 1	6
The moco	- - -	2 5 0	0 2	9
The gourde or dollar	- - -	9 0 0	0 9	0
The ecu of six livres	- - -	9 17 6	0 9	10½
The Louis d'or	- - -	40 10 0	2 0	6
Guinea	- - -	45 0 0	2 5	0
Napoleon of 40 francs	- - -	66 13 4	3 6	8
Doubleloon	- - -	144 0 0	7 4	0

The following gold coins are taken by weight.

Portugal pieces, at	- - - -	22 livres per gros
Counterfeit ditto, coined in America, at 20 ditto per gros	- - - -	French and Spanish coins deficient in weight, at
		} 19l. 15s. per gros
English ditto at 8 livres, 8 sols per dwt., that is, 7 sols per English grain.	- - - -	

WEST INDIES.

In the French part of St. Domingo, or Hayti, accounts are mostly kept in dollars and cents, as in the United States. The monies in circulation here are nearly the same as in the leeward islands. Dollars are valued at 4s. 6d. sterling, with halves and quarters in proportion: 11 escalins pafs for 1 dollar, and 1 escalin is reckoned at 9 cents. Doubloons pafs for 16 dollars; joes for 8 ditto; French crowns for 1 dollar 9 cents, and the half-crowns in proportion; French pieces of 5 francs pafs for 9 escalins, or 81 cents.

In the Dutch colonies of St. Eustatia, St. Martin, Curaçoa, accounts are kept in pieces of eight; that is, piaftres current of 8 reals or schillings, each real being subdivided into 6 stivers.

The piaftre gourde or Spanish dollar paffes for 11 reals or bits; and thus the current piaftre is worth 3s. 5d. sterling, reckoning the dollar at 4s. 8d. sterling.

The joe paffes here for 11 piaftres current; the Spanish single pistole for 4½ piaftres, more or less; the other Spanish and Portuguefe gold coins in proportion.

In the settlements of Surinam, Berbice, Demerary, and Essequibo, accounts are kept in guilders of 20 stivers; the silver being divided by some into 8 duits, and by others into 12 pennings.

All the coins of Holland circulate here, and are mostly reckoned at 20 per cent. above their value in Dutch currency.

The following is their general rate, as well as that of other monies.

<table style="width: 100%; border-collapse: collapse;"> <tr><td>10 Dubbelties =</td><td style="text-align: right;">gdrs. stiv. 1 0</td></tr> <tr><td>The bit - =</td><td style="text-align: right;">0 5</td></tr> <tr><td>Seftehalf - =</td><td style="text-align: right;">0 5½</td></tr> <tr><td>Schilling - =</td><td style="text-align: right;">0 6</td></tr> <tr><td>Guilder - =</td><td style="text-align: right;">1 4</td></tr> <tr><td>Dalder - =</td><td style="text-align: right;">1 10</td></tr> <tr><td>Rixdollar - =</td><td style="text-align: right;">3 0</td></tr> </table>	10 Dubbelties =	gdrs. stiv. 1 0	The bit - =	0 5	Seftehalf - =	0 5½	Schilling - =	0 6	Guilder - =	1 4	Dalder - =	1 10	Rixdollar - =	3 0	<table style="width: 100%; border-collapse: collapse;"> <tr><td>Spanish dollar =</td><td style="text-align: right;">gdrs. stiv. 3 0</td></tr> <tr><td>Ducatoon - =</td><td style="text-align: right;">3 3</td></tr> <tr><td>Gold ducat =</td><td style="text-align: right;">6 6</td></tr> <tr><td>Guinea - =</td><td style="text-align: right;">14 10</td></tr> <tr><td>Ryder - =</td><td style="text-align: right;">16 16</td></tr> <tr><td>Joe - =</td><td style="text-align: right;">22 0</td></tr> <tr><td>Doubloon - =</td><td style="text-align: right;">42 to 44</td></tr> </table>	Spanish dollar =	gdrs. stiv. 3 0	Ducatoon - =	3 3	Gold ducat =	6 6	Guinea - =	14 10	Ryder - =	16 16	Joe - =	22 0	Doubloon - =	42 to 44
10 Dubbelties =	gdrs. stiv. 1 0																												
The bit - =	0 5																												
Seftehalf - =	0 5½																												
Schilling - =	0 6																												
Guilder - =	1 4																												
Dalder - =	1 10																												
Rixdollar - =	3 0																												
Spanish dollar =	gdrs. stiv. 3 0																												
Ducatoon - =	3 3																												
Gold ducat =	6 6																												
Guinea - =	14 10																												
Ryder - =	16 16																												
Joe - =	22 0																												
Doubloon - =	42 to 44																												

The chief circulating medium here is paper, issued by government.

In 1809 a new silver coinage was minted at the Tower of London for these colonies, consisting of pieces of 3, 2, 1, ½, and ¼ guilders. The larger piece weighs 15 dwt.; and is 1 oz. 6 dwt. worse than English standard. Its value therefore is, 3s. 5d. sterling, or computing it as the dollar is now rated in the West Indies (*i. e.* at 4s. 8d.), its value is 3s. 8¼d., and the smaller pieces in proportion. They are marked on the reverse, COLONIES OF ESSEQUIBO AND DEMERARY TOKEN; and the king's head is on the obverse.

The exchange with London should be about 12 guilders for 1l. sterling, but it varies considerably above this, even to 20 guilders and upwards.

In the Danish islands accounts are kept in piaftres or rix-dollars current (called also pieces of eight), subdivided into 8 schillings or bits, and each bit into 6 stivers: accounts are also kept in dollars of 100 cents, as in America. The silver coins struck for the Danish islands are quadruple, double, and single bits, and pieces of 1 and 3 stivers. The Spanish dollar paffes for 12½ bits, and each bit for 6¼ stivers. The leeward currency is used in the Danish islands in the purchase or negociation of bills on England: gold is valued at 1 dollar per dwt. or 4½d. currency per English grain.

The monies, coins, weights, and measures of the Spanish islands are the same as those in Spanish America, or Mexico; accounts being kept in pesos or dollars of 8 reals, subdivided into 16 parts, and also into 34 maravedis de Plata Mexicanos. The gold coins are doubloons of 8 escudos d'oro, worth 15 pesos; halves and quarters in proportion. The silver coins are, pesos Mexicanos or dollars, with halves and quarters,

called pecetas Mexicanas; also eighths and reals, and sixteenths, in due proportion.

Trinidad, having been for many years in the possession of the English, has adopted the denominations of money of the English islands. Accounts therefore are here kept in pounds, shillings, and pence leeward currency; and also in dollars and bits, the bit being the 9th part of a dollar.

There are here silver pieces of half bits and quarter bits. The Spanish, Portuguefe, and English gold coins pafs as follows in Trinidad.

			Leeward Currency.		
	dwt. gr.	dol. bits.	l.	s.	d.
Doubloon -	17 8	15 8	7	4	0
Half ditto -	8 16	7 8½	3	12	0
Pistole -	4 8	3 8¼	1	16	0
Half ditto -	2 4	2 0	0	18	0
Joe -	7 12	6 8	3	2	0
Guinea -	5 8	4 8	2	4	0
Half ditto -	2 16	2 4	1	2	0
One-third ditto	1 19	1 5¾	0	14	8

Gold here is valued at 8s. 3d. currency per dwt. or 4½d. per grain.

The weights and measures here are the same as in England, except that the cwt. is reckoned only 100 lbs. avoirdupois.

The monies and currency of St. Bartholomew island are the same with those of the other leeward islands.

The regulations to which the West India exchanges are subject are as follow. When bills drawn in the West Indies on London are not duly honoured, they are returned to the drawer, with the following charges.

	Damages.	Interest per Annum.	Time how charged.
Jamaica	8 per cent.	6 per cent.	{ from date of the bill. { from the time of presentation with protest.
Barbadoes	10 ditto	6 ditto	
Grenada	10 ditto	6 ditto	
St. Vincent	10 ditto	8 ditto	{ from the bill falling due.
Tobago	10 ditto	8 ditto	
Trinidad	10 ditto	6 ditto	{ from date of the protest.
Dominica	10 ditto	6 ditto	
Nevis	10 ditto	8 ditto	
Montserrat	10 ditto	8 ditto	
Antigua	10 ditto	8 ditto	
St. Kitt's	10 ditto	8 ditto	
Tortola	10 ditto	8 ditto	
Demerara	25 ditto	6 ditto	
Essequibo			
Berbice			
Surinam	10 ditto	10 ditto	{ from date of the protest.
St. Thomas			
St. John			
Santa Cruz			

There are occasionally other charges besides the above, such

such as postage, notarial expences, and difference of exchange.

If a bill, drawn in the West Indies on any part of Great Britain, be noted for non-acceptance, the holder may oblige the drawer, by legal process, to give security in the island for the amount, without waiting for the bill being protested for non-payment. See Kelly's Cambist, vol. i.

WEST Island, in *Geography*, one of the smaller Philippine islands, near the south coast of Mindoro. N. lat. $12^{\circ} 18'$. E. long. $121^{\circ} 12'$.—Also, a small island at the east entrance of the straits of Sunda. S. lat. $5^{\circ} 27'$. E. long. $106^{\circ} 20'$.—Also, a small island in the East Indian sea, near the fourth coast of Cumbava. S. lat. $8^{\circ} 49'$. E. long. $119^{\circ} 2'$.

WEST Kirk, a town of the island of Westra, in a bay on the fourth coast. N. lat. $59^{\circ} 8'$. W. long. $2^{\circ} 51'$.

WEST Houghton, a township in the parish of Dean, and county of Lancaster, England, contained, in 1811, 663 houses and 3810 inhabitants.

WEST Penn, a township of Pennsylvania, in the county of Northampton, containing 947 inhabitants.

WEST Point, a town of Virginia, on the York river; 35 miles E. of Richmond. N. lat. $37^{\circ} 30'$. W. long. $76^{\circ} 56'$.

WEST Point, a town of New York, on the right bank of the Hudson river, in the county of Orange. This was a post of great consequence, especially with respect to the communication between the northern and the middle colonies, and the possession very desirable to the British general, who entered into a treaty with general Arnold the commander to betray it. The adjutant-general of the British army, major André, was employed by sir Henry Clinton as the agent on this business, and being discovered, he was executed as a spy; 42 miles N. of New York. N. lat. $41^{\circ} 23'$. W. long. 74° .

WEST Point, a cape at the western extremity of the island of Anticosti. N. lat. $49^{\circ} 50'$. W. long. $64^{\circ} 30'$.

WEST River, a river of Virginia, which runs into Black bay, N. lat. $36^{\circ} 30'$. W. long. $76^{\circ} 17'$.—Also, a river of Maryland, which runs into the Chesapeake, N. lat. $38^{\circ} 54'$. W. long. $76^{\circ} 42'$.—Also, a river of the province of Maine, which runs into Machias bay, N. lat. $44^{\circ} 45'$. W. long. $67^{\circ} 19'$.

WEST River, or *Wantassic*, a river of Vermont, which runs into the Connecticut, N. lat. $42^{\circ} 50'$. W. long. $73^{\circ} 31'$.

WEST River Mountain, a mountain of New Hampshire, near West river.

WEST Town, a township of Pennsylvania, in the county of Chester, with 790 inhabitants.

WEST Wain, the west shore of Hudson's bay.

WESTBROUGH, a town of Massachusetts, incorporated in 1717, in the county of Worcester, containing 1048 inhabitants; 33 miles W. of Boston.

WESTBURY, a market-town and borough in the hundred of the same name, and county of Wilts, England, is situated at the distance of 24 miles N.W. by W. from Salisbury, and 97 miles W. by S. from London. Nothing is known with certainty of its history, till the reign of Edward I., when it was constituted a corporate town by charter, under the jurisdiction of a mayor, recorder, and twelve capital burgesses. Westbury sends two members to parliament, and has done so regularly since the 27th year of Henry VI., who renewed its charter of incorporation, and bestowed upon it the additional privilege of being represented in the national councils. The right of election is in the holders of burgage tenures, being resident within the borough, and not receiving alms: the mayor is the re-

turning officer. The town consists principally of one long street, running nearly in a direction north and south. According to the population return of the year 1811, it contained 351 houses, and 1790 inhabitants, who were chiefly engaged in the manufacture of woollens. A market is held weekly on Fridays; and two fairs annually, when there is usually a large supply of cattle, horses, sheep, pigs, cheese, &c. The borough and hundred of Westbury form only one parish: for the former, a court-leet is held by the mayor in November annually; and for the latter, one in May by the steward of the lord of the manor, at which two high constables are appointed for securing the public peace. The only public buildings in this town which demand particular notice, are the town-hall and the church. The hall is a convenient edifice, in which the borough-courts are held: it is situated near the centre of the town, and is also appropriated in part as a wool-hall. The church is a large ancient structure of stone, with a tower in the middle. In it are several monuments in honour of persons of considerable note.

About a mile to the south of Westbury is the village of Leigh, commonly called Westbury-Leigh; supposed by several antiquaries to be the place designated in Asser by the word *Ægges*, where king Alfred encamped on the night previous to the battle of Ethandune.

Heywood house, situated about two miles due north from Westbury, was built in the reign of king James I., by James, lord Ley, afterwards created earl of Marlborough. It was long possessed by the family of Phipps; but is now the property and seat of Abraham Ludlow, esq.—*Beauties of England and Wales*, vol. xv. Wiltshire. By J. Britton, F.S.A. 1814.

WESTBURY, a village in the hundred of Ford, and county of Salop, England, situated 8 miles W. by S. from Shrewsbury. In this village is a respectable free-school; and in the church, among other monuments, is one raised to the memory of general Severne, who inherited Wallop-hall, in this parish. About two miles S.W. of Westbury is Cawfe, or Caux-Castle, which is supposed to have been erected by Roger Corbett, who held of earl Roger de Montgomery a tract of land consisting of thirty-nine manors. It is conjectured that he gave the above name to this his capital seat, in allusion to a castle in the Pays de Caux, in Normandy. As he and his son probably joined with Robert de Belesme in his rebellion, the castle is supposed to have been forfeited to Henry I., who gave it to Paris Fitz-John, from whom it was taken by the Welsh. It was restored to the original lords, and in the first of king John a weekly market was obtained for it, at the instance of Robert Corbett. Its proximity to the Welsh frontiers rendered its tenure uncertain, and we find that it was again seized by the Welsh, and restored by Henry III. In the reign of Edward III., the male line of the family becoming extinct, the castle was transferred, by marriage of a daughter of the house, to the Staffords, earls of Stafford; on the execution of the last of whom, Edward, duke of Buckingham, it was forfeited to the crown, but was restored to his son Edward. It was alienated in the reign of Elizabeth to Robert Harcourt, from whom it descended to lord viscount Weymouth. The site of this castle is perhaps one of the most lofty and commanding in the whole range of the Salopian frontier. It is an insulated ridge, rising abruptly from a deep ravine on one side, and sloping towards a vast valley, bounded by the Stiper-stones on the other. The keep-mount is singularly steep and towering; it must have been ascended by steps, or by a winding path, but no traces of either at present remain: part of a well is still distinguishable;

inguishable; the castle itself is nearly destroyed. Parts of one of the entrance-gateways, evidently of a more recent date than the original castle, are still to be discerned.—*Beauties of England and Wales*, vol. xiii. Shropshire. By R. Rylance, 1811.

WESTBURY, a township of Lower Canada, on the river St. Francis.

WESTENBERG, a town of the marggravate of Anspach; 6 miles N.E. of Anspach.

WESTENSEE, a lake of the duchy of Holstein; 8 miles E. of Rendsburg.—Also, a town of the duchy of Holstein, on the side of the lake of the same name; 8 miles S.E. of Rendsburg.

WESTERBURG, a town of Germany, which gives name to a lordship, situated on the Westerwald. The lords of Westerburg succeeded the counts of Leiningen. They are counts of Leiningen and lords of Westerburg; 16 miles W.N.W. of Weilburg.

WESTERHAM, a market-town in the hundred of Westerham and Eden-bridge, late of Sutton, and county of Kent, England, is situated near the confines of the county towards Surrey, at the distance of 5 miles W. from Seven-Oaks, and 22 miles S.E. by S. from London. The manor was given by Edward I. to the abbey at Westminster, for the performance of certain religious services for the repose of the soul of queen Eleanor. He also granted several privileges to the abbot, which were confirmed by Edward III., who also gave permission to hold a weekly market at Westerham, which is still continued. After the dissolution, Henry VIII. conveyed these estates to sir John Gresham, younger brother of sir Thomas Gresham, the founder of the Royal Exchange: and his descendant, sir Marmaduke Gresham, sold this manor to the Wardes of Squerries, a respectable seat in this parish, near the west end of the town; and John Warde, esq. is now the owner. Westerham is stated, in the population return of 1811, to contain 272 houses, and 1437 inhabitants. The market is now held on Wednesday; and here are two annual fairs. The church, a spacious edifice, contains a great variety of sepulchral memorials; among which is a neat cenotaph in commemoration of major-general James Wolfe, a native of this town, who was slain before Quebec in 1759. This town also gave birth to Dr. Benjamin Hoadley, who, in the last century, was successively bishop of Bangor, Hereford, Salisbury, and Winchester.

Some singular land-slips are recorded by Haisted, as having happened at different periods in this parish. The first which is mentioned occurred in 1596, near Oakham-hill, about a mile and a half southward from the town; where about nine acres of ground continued in motion for eleven days; some parts sinking into pits, and others rising into hills. A similar occurrence took place in 1756, at Toy's-hill, about a mile and a half to the east of the town, where a field of two acres and a half underwent considerable alterations of surface, from an almost imperceptible motion.—*Beauties of England and Wales*, vol. viii. Kent. By E. W. Brayley, 1808. Haisted's History of Kent, 1778.

WESTERHAUSEN, a town of the bishopric of Halberstadt; 3 miles E. of Regenstein.

WESTERLEY, a town of America, in Rhode island; 30 miles S.S.W. of Providence.

WESTERLOO, a town of France, in the department of the Two Nethes; 15 miles E.N.E. of Malines.

WESTERMO, a town of Sweden, in Sudermanland; 62 miles W. of Stockholm.

WESTERN *Amplitude, Church, Horizon, and Ocean.* See the several articles.

WESTERN, in *Geography*, a town of the state of Massachusetts, in the county of Worcester, containing 1014 inhabitants; 20 miles W. of Worcester.

WESTERN *Islands.* See AZORES.

WESTERN *Islands.* See HEBRIDES.

WESTERN *Reef*, rocks in the Spanish Main, near the Mosquito shore. N. lat. $14^{\circ} 42'$. W. long. $82^{\circ} 25'$.

WESTERNACH, a river of Bavaria, which runs into the Mindel, 2 miles N. of Mindelheim.

WESTEROS, or WESTESAS, or *Western Arosia*, so called to distinguish it from Odra Aros, or Eastern Arosia, the ancient name of Upsala, a town of Sweden, and capital of Westmannland, situated on a small river close to the lake Mæler. This is esteemed by the native writers a place of high antiquity; and they derive its appellation, by a fanciful etymology, from the river Ar, and Os, a mouth, and suppose it alluded to by Tacitus, and by Jornandes the Gothic historian. However this be, the name occurs in the earliest times of Swedish history. Westeros carries on a considerable commerce with Stockholm across the lake Mæler; particularly in copper and iron from the mines, which abound in the province of Westmannland. It is a large straggling town, composed of wooden houses, and contains the ruins of an ancient palace, formerly inhabited by the kings of Sweden. It is a bishop's see; and the cathedral, which is built with brick, is celebrated for the tower, esteemed the highest in the kingdom; the lower part of this tower is square, and supports an octagon spire, covered with copper. Within this cathedral is the tomb of Eric XIV. Westeros has often suffered much by fire, particularly in 1714. It is 36 miles W.S.W. from Upsal. N. lat. $59^{\circ} 36'$. E. long. $16^{\circ} 30'$.

WESTEROS, a township of New York, in Oneida county, bounded N. by Boonville, E. by Steuben, S. by Floyd and Rome, W. by Lee, which was erected from the W. part in 1811. It is watered by small head waters of Mohawk river, and has plenty of mill-seats. The soil, surface, and products, are similar to those of Steuben and the adjoining towns. In 1810, the population was 2416, and the number of electors was 275. The lands are well cultivated and productive. The inhabitants are rich, and are clothed in household manufacture.

WESTERWALD, a district of Germany, in the north part of Wetteraw, or Wetteravia.

WESTERWALD *Earth*, a kind of earth mentioned by Agricola, of a whitish-yellow colour, of a like nature to the terra Silesiaca, but preferable to it, as yielding more salt. He tells us, that it dissolves silver so much better than other menstrea, as to render it potable, and capable of being prepared into a useful medicine in cephalic cases. Boyle's Works, vol. i. p. 501.

WESTERWYCK, in *Geography*, a sea-port of Sweden, in the province of Smaland, situated in a bay of the Baltic. This bay is called Sparefund; and near it is a custom-house, where all homeward and outward bound ships are searched. Westerwyck formerly stood two Swedish miles higher up in the country, on the spot where the market-town of Gammel now stands. It has a good harbour, a commodious quay, and a cloth manufacture, and carries a brisk trade in ship timber, and all sorts of naval stores; 68 miles N. of Calmar. N. lat. $57^{\circ} 45'$. E. long. $16^{\circ} 24'$.

WESTEY, a township of Ohio, in the county of Washington, containing 172 inhabitants.

WESTFIELD, a river of Massachusetts, which runs into the Connecticut, 4 miles S. of Springfield.—Also, a town of the state of Massachusetts, in the county of Hampshire, containing 2130 inhabitants; 6 miles W. of Springfield.

field.—Also, a post-town of New York, on the east side of lake George; 6 miles S. of Ticonderoga.—Also, a township of New York, in Richmond county, in Staten island. At its southern extremity in the S.W. is a ferry of three-quarters of a mile to Amboy, in New Jersey. It has one church near the centre, and well cultivated land. The whole population in 1810 was 1444, and the number of electors 139.—Also, a town of Vermont, in the county of Orleans, containing 149 inhabitants.—Also, a town of New Jersey, in the county of Essex, containing 2152 inhabitants; 8 miles W. of Elizabethtown.

WESTFORD, a town of Vermont, in Chittenden county, containing 866 inhabitants.—Also, a post-town of Massachusetts, in the county of Middlesex, containing 1330 inhabitants; 28 miles N.W. of Boston.—Also, a township of New York, in Otsego county; 8 miles S.E. of Cooperstown, erected in 1808 from the N.W. part of Worcester. Its surface is broken by hills and valleys, but has much rich mould in the valleys. The hills are adapted to grazing, and it has many tracts of meadow land. Its timber consists of maple, beech, ash, elm, bass-wood, and pine; and the whole is irrigated abundantly by springs and brooks. In 1810 the whole population consisted of 1215 persons, and the number of electors was 73, and that of taxable inhabitants 177.

WESTGATE BAY, a bay of the Thames, on the coast of Kent, W. of Margate.

WEST GREENWICH, a town of Rhode island, in the county of Kent, with 1619 inhabitants.

WESTHAM, a town of Virginia; 4 miles N.W. of Richmond.

WESTHAMPTON, a post-town of New York, in the south-east part of Long island.—Also, a township of Massachusetts, in the county of Hampshire, containing 793 inhabitants; 7 miles W. of Northampton.

WEST HANOVER, a township of Pennsylvania, in the county of Dauphin, containing 2461 inhabitants.

WESTHAVEN, a township of Connecticut; 3 miles W.S.W. of Newhaven.

WESTHOFEN, a town of France, in the department of Mont Tonnerre; 5 miles N.N.W. of Worms.—Also, a town of France, in the department of the Lower Rhine; 12 miles W. of Straßburg.

WESTHOVEN, a town of Germany, in the county of Mark, at the foot of a mountain near the Roer; once the domain of the celebrated Witikind, and possessed of considerable privileges; 4 miles S.W. of Schwiert.—Also, a town of Vermont, in the county of Rutland, containing 679 inhabitants.

WESTING, in *Navigation*, the same with departure.

WESTLAND, in *Geography*, a town of Ohio, in the county of Guernsey, with 250 inhabitants.

WESTMAES, a town of the island of Beyerland; 12 miles W. of Dort.

WESTMAN, or WESTMONIA, an island in the North sea, near the coast of Iceland. N. lat. $63^{\circ} 20'$. W. long. $20^{\circ} 28'$.

The Westman islands suffered very much about the commencement of the seventeenth century, by the piracies of the Algerines; almost their whole population being destroyed or carried into captivity. In 1627 a large body of Algerine pirates landed on various parts of the southern coast of Iceland; and not satisfied with the booty they obtained, murdered between forty and fifty of the inhabitants, and carried off nearly four hundred prisoners of both sexes. These unfortunate captives, transported to Algiers, were exposed there to so much wretchedness, that nine years afterwards, when the king of Denmark obtained their liberty by ran-

som, only thirty-seven out of the whole number were found to be surviving; of these, thirteen succeeded in reaching their native land. A priest named Olaus Egilson, a captive, and released in 1629, left a MS. relation of this event, which has been since published in Danish.

WESTMAN, a town on the W. coast of the island of Stromoe.

WEST MANCHESTER, a township of Pennsylvania, in the county of York, containing 978 inhabitants.

WESTMANNLAND, or WESTMANIA, a province of Sweden, bounded on the north by Dalecarlia, on the east by Upland, on the south by Sudermanland, Nericia, and the Mæler lake, and on the W. by Warmeland; about 110 miles in length, and 80 in breadth where widest. The soil is fertile, and consists mostly of arable lands, with meadows, pastures, and very fine woods in proportion; and it is reckoned the most famous province in the kingdom for mines. The iron trade carried on by the inhabitants of Westmannland, is the most considerable in all Sweden: the quantity of iron exported annually from Westeros, Arboga, and Kioping, is very large. The south part of the province chiefly consists of arable and meadow lands, and supplies the inhabitants of the mine districts with corn; and the northern parts abound in mine-works, and fine woods. Westmannland is well watered, both with rivers and lakes, which yield a vast plenty of fish; and the Mæler lake is a great advantage to its commerce, as it opens a passage from this province to Stockholm. The chief subsistence of the inhabitants is derived from agriculture and the mines, breeding of cattle and fishing. The wood, hammer-mills, &c. also employ a great many hands.

WEST MARLBOROUGH, a township of Pennsylvania, in the county of Chester, containing 917 inhabitants.

WESTMEATH, a county of Ireland, which formerly was a part of the kingdom of Meath, but on the division into counties was separated from it, and both now form a part of the province of Leinster. It has Cavan on the N., Meath on the E., the King's county on the S., Roscommon, from which it is separated by the Shannon, and Longford on the W. Its greatest extent from E. to W. is 33 Irish (42 English) miles, and from N. to S. 27 Irish (34 English) miles. Its area measures 231,538 acres, or 361 square miles Irish, equal to 371,979 acres, or 577 square miles English measure. The number of parishes is 62, of which 21 have churches, and all but three are in the diocese of Meath. The population was computed by Dr. Beaufort to be 69,000. No part of this country is embarrassed with mountains, but a great number of acres are rendered unproductive by large lakes and extensive bogs; yet the convenience of fuel, the abundance of gravelly hills, and the variety of prospects which arise from these beautiful lakes, and the undulating form of the surface, render it a very pleasant and healthful country. The soil is in general light, but in some places deep and rich; and though there is more of it kept under grass than employed in tillage, yet the plough is by no means neglected; for after supplying the home consumption, the farmers of this county largely contribute to the exportation of oats from Drogheda. The Royal Canal from Dublin to Tarmonbury, on the Shannon, was to pass through this county, and it has been carried as far as Mullingar; but the difficulties into which the company has fallen make it doubtful when the original design will be completed. Westmeath is remarkably well watered. Besides the Shannon, which forms part of its western boundary, the Inny and Brosna, two rivers of considerable extent, pass through its lakes, and insulate the greater part of it. The Inny rises in the county of Cavan, and first enters Lough Shelin, which separates that county

from Westmeath; then in its course passing through the loughs Derveragh and Iron, it is at length lost in that vast expanse of the Shannon, called Lough Ree, or the Royal Lake. The Brosna, rising in Lough Iron, flows from it to Lough Hoyle, after quitting which it passes the town of Mullingar; it then expands into Lough Ennel, and when again contracted, flowing by the town of Kibeggan, it enters the King's county, through which it proceeds to the Shannon. As Westmeath is nearly central, so its streams flow in both directions. Those which have been already mentioned, joining the Shannon, are mixed with the Atlantic ocean; whilst other small streams, being collected in the river Dele, take an eastern direction, and being united with the Boyne, flow to the Irish sea.

Besides Lough Shelin on the north, and Lough Ree on the western boundary, there are six considerable lakes in this county, and several small ones. These are well stored with fish of various kinds, and afford a number of beautiful prospects; yet it is to be regretted that so many acres should be almost an unprofitable waste. The fish found in these lakes are, perch, pike, bream, tench, trout, and very fine eels. The trout are often of ten pounds weight, and as red as a salmon. Such is the abundance, that Mr. Young tells us that a child with packthread and a crooked pin is able to catch perch enough in an hour to support a family for a day. This territory once belonged to Mortimer, earl of March, who married the daughter and heiress of Lionel, duke of Clarence, third son of Edward III. This nobleman resided much in Ireland, and was probably induced by the beauties of the situation to build a palace at Fahatty, on the banks of Lough Derveragh, one of the finest of these lakes, the remains of which were said above a century ago to retain "the lineaments and footsteps of ancient state and magnificence." When Richard II. was deposed by Henry of Lancaster, Mortimer was the next in succession to the throne, and he found it necessary to conceal himself, which he did by retiring to Fahatty. By a marriage with his daughter, Richard, duke of York, succeeded to his Irish property, and to his right of succession. This nobleman resided in Ireland for some years as lord-lieutenant, before circumstances enabled him to urge his claim to the crown, which, after a long and bloody civil war, was obtained by his son. The attachment of the settlers in Ireland to this family was shewn in the reign of Henry VII., by their readily embracing the cause of Simnel and Warbeck.

Mullingar is the shire town of Westmeath; but Athlone is a place of more consequence. For an account of these, and of Kinnegad, Kibeggan, Fore, &c. see their respective articles in this work. Westmeath has three representatives in the imperial parliament, two for the county, and one for the borough of Athlone.—Beaufort, Young, Collected, &c.

WESTMINSTER, a spacious, populous, and important city of the county of Middlesex, England, is situated on the north bank of the river Thames, and constitutes the western extremity of the metropolis. Although in every respect, local position alone excepted, independent of London, Westminster constitutes a most essential portion of the great metropolis of the British empire. The line of demarcation between these two cities has long indeed, by the rapid increase of buildings, ceased to be perceptible to general observation; but it is not the less real and efficient. The inhabitants of Westminster, it is true, consider themselves, in a general sense, as belonging to London; but for the purpose of internal discrimination, they confine the term Westminster to its original signification, the site and the environs of the present collegiate, formerly the abbey-church of St. Peter. Considering the city in this restricted

sense, and St. Peter's church as the centre, the latitude of Westminster is $51^{\circ} 29' 52''$ N., and the longitude $0^{\circ} 7' 32''$ W., from the meridian of the royal observatory in Greenwich-park. St. Peter's church bears from St. Paul's in London W.S.W. 2900 yards, or above one mile and five furlongs. The form of Westminster, in its present extended state, is triangular, having the base along the line of Oxford-street, which separates it from Marybourne on the north; and the vertex on the Thames, where the buildings terminate at Millbank on the south. The base, from Tyburn turnpike, at the western extremity of Oxford-street, to the vicinity of Chancery-lane, at Lincoln's-inn, measures nearly two miles. The side on the west from that turnpike to the vertex on Millbank, is also about two miles. The remaining side on the east, in a right line from the vertex to Chancery-lane, is one mile and six furlongs. The ground occupied by the buildings of the city and liberties therefore contains one square mile and a half, or about one thousand acres. Westminster and London come into contact at Temple-bar, the boundary of the former city commencing at the Thames on the west of the Temple-buildings, and running north to Lincoln's-inn. There quitting London, it turns westward to the eastern extremity of Oxford-street, excluding the church and parish of St. Giles-in-the-Fields, which belong to the county of Middlesex.

General View of Westminster.—From the extent of ground occupied by the city and liberties, and from the general population, amounting, by the enumeration of 1811, to 162,085 persons, Westminster would, in another position, be fully entitled to rank high among the secondary capitals of Europe. In common language, the great aggregate of Westminster is termed a city; but that term belongs only in strictness to the immediate environs of St. Peter's church, while all the other parts of the community are spread over the district or liberties belonging to the monastic establishment, of which that church was a principal member. The city is of great antiquity, in the sense in which antiquity is estimated in Britain; but the occupation of the liberties is of comparatively late date. This portion of Westminster may also be distinguished, as to its age, into the old and the new towns, by a line running north from Charing-cross up St. Martin's-lane into Crown-street, Soho-square, and terminating near St. Giles's church, at the eastern end of Oxford-street. On the east of this line lies the old town, and on the west spreads out the new. The distribution of the streets, and the construction of the buildings of the city, sufficiently indicate their early origin; an observation not unsuitable to the extremities of the old town. The new town, on the other hand, having been formed when better notions of distribution and arrangement began to prevail, possesses a high proportion of all the advantages which such notions were calculated to produce. The abbey-church of St. Peter is distant from the limits of London at Temple-bar, by the present streets along the Strand and Whitehall, about 2400 yards, or one mile and three furlongs; but from Temple-bar to the extremity of the Strand, at Charing-cross, is only 1500 yards, or seven furlongs. The origin of this street is manifest from its name, having been only a road along the strand, or bank of the Thames, leading through the village of Charing to Westminster. Without keeping however precisely along the margin of the water, the road, owing to the steep fall of the bank, was carried forward at such a distance as to permit spacious houses and gardens to be formed on the slope between it and the river. The residence of the court, in early times, was frequently in the Tower of London, or at some place at a distance from the capital; but under Henry III., who

reigned from 1216 to 1272, the court usually resided in Westminster. The courts of justice, which had before accompanied the king in his motions, were, by his confirmation of *Magna Charta* in 1225, made stationary in Westminster, where the parliament also generally met. For the convenience of attendance on the king, the courts of justice, and the parliament, for the enjoyment also of good open air, and an agreeable prospect, many of the nobles, and especially of the bishops, erected palaces along the banks of the river. Persons of inferior station, whose chief dependence for business and subsistence rested on those great men, were necessarily induced to fix their abode in their vicinity. In this way, a chain of dwellings, of various sorts, was progressively raised between the cities of London and Westminster, and united both with the intervening village of Charing. The situations of those palaces, or inns, as they were called, are preserved to the present day, in the succession of streets retaining their names, which communicate from the Strand on both sides, especially to the river. Thus, for instance, from Temple-bar we come to streets bearing the names of Essex, Arundel, Norfolk, Surry, Somerset, Savoy, Beaufort, Cecil, Salisbury, Durham, York, &c., all calling up personages memorable in former times; but of the houses to which those names belonged, no vestige, if we except the fragments of the palace of the Savoy, and the present Northumberland-house, can now be said to remain. The opposite side of the Strand being cut off from the use and the view of the Thames, was of course little frequented; but Exeter-change still indicates the residence of the celebrated Cecil, lord Burleigh, whose son Thomas became earl of Exeter. Bedford and Southampton streets declare the origin of their names. As late as in the year 1353, when Edward III. was on the throne, the Strand was an open highway, crossed and cut up by water-courses from the higher grounds. It was then repaired, but not before great complaints had been made: for in the petition of the persons who lived near the palace of Westminster to Edward II., "the footway from Temple-bar to the palace" is stated to be so bad, that "the feet of horses, and rich and poor men, received constant damage, especially in the rainy season; the footway being interrupted by thickets and bushes." From Temple-bar to the palace of Savoy, the Strand seems to have been paved, or properly made about 1385, in the reign of Richard II.: but the paving went no further till the latter part of Elizabeth's reign; and in the 35th of Henry VIII. the road was stated to be "full of pits and sloughs, very perilous and noisome." In the year 1533 the Strand took the form of a street, bordered on each side with houses and gardens; among which was Covent-garden, corruptedly so called from the garden of the convent, or abbey of Westminster, to which it belonged. Charing was still a detached village; St. Martin's church stood literally in the fields; and St. Giles's, also situated in the fields, stood in a distant hamlet in the country. Such, however, was the increase of the town in the end of Elizabeth's reign, that in 1600 St. Martin's-lane was built on both sides; and although St. Giles's church still stood detached, the great west road, now called Holborn, (properly Old-bourne, from the name of a small brook running along it,) was formed into a street all the way into London at Fleet-ditch. Covent-garden and Lincoln's-inn-fields were partially built on, as were Drury-lane and Long-acre, and principally inhabited by the gentry. The village of Charing was long before this time, or in 1292, adorned with a cross by Edward I., being the last spot where the body of his queen rested on the way to Westminster. In 1647 it was removed, and in part employed in pavement at Whitehall;

but soon after the Restoration, its place was filled, as it now is, by a statue of Charles I. on horseback. From Charing to Westminster, the bank of the Thames was occupied by the residences of royal, or other distinguished personages. First was a palace for the king of Scotland, when he came to court to attend the parliament, of which, on account of lands he held in England, he was considered a member. An ancient painting, formerly in the college of arms in London, represented Edward I. sitting in parliament, having on his right-hand Alexander III., king of Scotland; and on his left, Llewellyn, prince of Wales. The palace has long been effaced, but its site is still called Scotland-yard. To this succeeded in position the palace of Whitehall, which will be noticed in another place. The church of St. Martin stands within the limits of the old quarter, but its parish originally extended over the whole of the new quarter of Westminster; and out of it, as buildings increased, the parishes of St. Paul, Covent-garden, St. James, St. Anne, and St. George, have successively been formed.

Among the various improvements lately introduced into the streets of Westminster, must be reckoned the substitution of gas-lights for oil-lamps, now much in use in shops as well as without doors. The gas, or vapour, is extracted, by a species of distillation, from pit-coal. Purified from the incombustible aerial substances with which it is extricated from the coal, by transmission through a body of water, the inflammable or carburetted hydrogen gas is conveyed by pipes, like water, to the places where it is wanted. By the admission of flame to the orifice of the pipe, the gas takes fire, producing together with a strong heat, a lively light of peculiar force and brilliancy. The coals from which, in London and Westminster, the gas is obtained with the greatest effect, are the Lancashire cannel, and the Scotch splint coals. Newcastle coal is found to be much less pure, but from its cheapness is now mostly used.

Origin and History of Westminster.—Much learning and more fancy have been employed in devising an etymology for the name of London; but the name of Westminster is too obvious to afford exercise for the skill or the ingenuity of the philologist or the antiquary. The Saxon terms composing the latter name evidently refer to the church of St. Paul, in London, in the east. Stowe indeed, and some later writers, carry the reference to a monastery, not far from the Tower of London, called the East-minster. But that establishment was founded only by Edward III., in the middle of the fourteenth century, long posterior to that of Westminster, and could not therefore have given origin to the latter institution. The history of Westminster is founded on, and closely interwoven with that of the monastery of St. Peter: for to the existence and importance of the latter, the rise, progress, and prosperity of the former must be attributed.

The site of the church and monastery of St. Peter was in early times an island, inclosed by the main channel of the Thames on the east, and by a collateral branch of that river on the west. History furnishes no information concerning the limits or the extent of this insulated tract; but by a careful examination of the ground, even under all its alterations, the course of the collateral branch may still be discovered. This branch seems to have broken off from the Thames to the east of Chelsea hospital, to have passed northward, along the natural hollow in which the water still flows to supply Chelsea water-works, and thence over a short interval, now covered with the houses of Pimlico, into the depression occupied by the canal in St. James's park, across the site of Whitehall into the Thames. In this case the island was in length from S.W.

WESTMINSTER.

to N.E. about one mile and three-quarters, and in breadth in the middle about half that distance. Of this spacious tract, by far the greatest portion must, in former times, have been regularly overflowed by each returning tide of the river; as it would be at the present time, were not the embankments bordering the Thames carefully preserved. The age of these mounds is unknown; but to no others than the heads of the monastery to whom the island belonged can their formation be reasonably ascribed; and to them is Westminster therefore indebted for the many advantages derived from the lands rescued from inundation. The embankments must have been constructed, and the ground within them well improved in 1386: for in that year abbot Litlington died in the manor-house of *Neyte*, situated within that space. So desirable was that situation, that the duke of Lancaster, styling himself king of Castille, had requested leave to reside in the house during the sitting of a parliament. The name of this place still survives, although absurdly corrupted into *Neat-houses*. In an authentic charter, dated in 785, Offa, king of Mercia, grants certain lands to the monastery of St. Peter: its situation is described to be in "Tornea in loco terribili ad Westmunster." In the writings of Sulcardus, a monk of this monastery who wrote in the eleventh century, the name is Thorneia. Both these names are supposed to be formed from the Saxon *Thorn-ey*, the isle of thorns and briars, expressing the wild uncultivated state of the "terrible spot" noticed by Offa. Forbidding as such a situation now would be, it bore a different aspect in ancient times; for it possessed alike security from attack, and seclusion from the world. To the religious establishment on Thorney, the rise, progress, and prosperity of Westminster are to be ascribed; but the origin and the date of that establishment itself are involved in obscurity. The probability, however, is, that it was founded by Sebert, king of the East Saxons, who died in 616. That it had in 785 acquired celebrity, is evident from the charter before-mentioned, granted by Offa. From Sebert's time the monastery seems to have been only a priory; but by Offa it was changed to an abbey, of which the abbots arose, in the course of a few years, to the highest dignity of which their rank was susceptible. To demonstrate more fully his attachment to the patron of the abbey, St. Peter, Offa in it deposited his coronation-robcs and regalia. From this circumstance, perhaps, as much as from subsequent papal authority, St. Peter's church afterwards became, and still is used for the inauguration of the English sovereigns; and to the dean, as successor of the abbot, are intrusted many of the implements and ornaments employed in that important function, which was first there performed on William the Conqueror, in 1066. After suffering severely in common with other works of the same character, by the ravages of the Danes, the abbey was restored by Edgar, who began to reign in 957, on the instigation of Dunstan, who removed thither, probably from Glastonbury, twelve monks of the order of St. Benedict. It is nevertheless to Edward the Confessor that the institution is principally indebted for its splendour. Sulcardus informs us that Edward had vowed to go to Rome, there to express his pious gratitude to heaven for his unexpected establishment on the English throne. The many inconveniences, however, by which the performance of this engagement must have been attended, induced him to substitute in its stead some other mode of testifying his thankfulness. He therefore undertook to rebuild the church and monastery of St. Peter in a magnificent manner, and endow them with ample revenues. Of the structure itself we only know from Matthew Paris, that "it was constructed in a new kind of arrangement, from which many persons in erecting churches

took a pattern, and strove to imitate it." Speaking of the same edifice, sir Christopher Wren refers to an account printed from an ancient manuscript. This account he translates into language proper for builders, in this way. "The principal area or nave of the church being raised high, and vaulted with square and uniform ribs, is turned circular to the east. This on each side is strongly fortified with a double vaulting of the aisles in two stories, with their pillars and arches. The cross-building, contrived to contain the choir in the middle, and the better to support the lofty tower, rose with a plainer and lower vaulting; which tower then spreading with artificial winding-stairs, was continued with plain walls to its timber-roof, which was well covered with lead." The striking novelty in this structure was probably the introduction of an imitation of a cross in the plan: for the earlier Saxon churches are supposed to have had no transepts. The grants of lands, and of relics, bestowed by Edward on his new foundation, were ample beyond all precedent. He likewise invested it with peculiar privileges, exempting it from all secular services and authority, even from episcopal superintendance. But this last exemption brought on each new abbot the trouble and expence of a journey to Rome, to be confirmed by his holiness in person. Edward died on the 5th of January, 1066, having survived but a few days the splendid ceremony of the consecration of the new structure. From these privileges, afterwards extended to a considerable space connected with the abbey, may be traced in a great measure the present civil constitution of Westminster. While Laurence was abbot in 1163, in the reign of Henry II., the power was obtained from pope Alexander III. for his using the mitre, ring, and gloves, distinguishing marks of episcopal dignity. But this privilege became, in the sequel, of still higher importance; for mitred abbots came to sit in parliament as well as bishops, and to enjoy every honour to which bishops, as lords of parliament, were entitled. Laurence dying before the papal approbation of the measure was formally announced, his successor Walter was the first abbot of Westminster who actually enjoyed the honours of the mitre. The reign of Henry III., of great importance in the history of England in general, is not less so to that of Westminster abbey in particular. In it the greater part of the edifice was rebuilt, in the lofty elegant style by which it is chiefly characterized; a style which about that time began to be adopted in ecclesiastical buildings throughout Europe. As early as 1220, although then only a youth, Henry laid the first stone of the chapel of the Virgin, which was afterwards superadded by the gorgeous structure of Henry VII.; but it was not until 1245 that he directed the church to be enlarged, and the tower, with the eastern part, to be constructed anew. In 1269 the building was opened for divine service, and the body of Edward the Confessor was deposited in a splendid shrine erected behind the high altar.

The abbey of Westminster is entitled to the peculiar veneration of every friend of literature, of science, and of civil and religious liberty; for within its bounds was erected the first apparatus for printing books employed in this island. William Caxton, a mercer of London, during a long residence on the continent as agent for the affairs of his company, and in 1464 as minister from Edward IV. to the duke of Burgundy, became acquainted with the art of printing, then very recently practised in Lower Germany. In 1471 he printed at Cologne a work which he had translated from the French into English; and returning home in the following year, he, under the patronage of the abbot of Westminster, commenced printing in the almonry, or eleemosynary adjoining to the abbey. In March 1474 appeared his book

on the "Game at Chefs," which may be regarded as the first production of the English press. (See PRINTING.) The honour of being the first protector of printing in England has been frequently assigned to John Islip: but this must be erroneous; for he became a monk only in 1480, and arose to be abbot only in 1500. To one of his predecessors, therefore, to Estency, elected in 1474, or rather to Millyng, elected in 1469, is the introduction of printing to be attributed. The abbacy of Islip is however memorable on another account. In it was founded, on the 24th of January, 1502-3, the celebrated chapel of Henry VII. Having obtained the crown as heir to Henry VI., he resolved to erect a sumptuous monument for his remains, in the expectation of his canonization. The first part of the project was carried into effect: but the court of Rome requiring a greater sum for compliance with his solicitation than the prudent Henry of Richmond cared to bestow, the last part of the project was relinquished. Westminster-abbey was now on the eve of great alterations. The schemes of Henry VIII. began to be put in practice. On the 16th of January, 1539-40 a surrender of the whole establishment was executed by abbot Benson of Boston, and twenty-four of the monks. The annual revenue is stated to have then been nearly 4000*l.*; a sum of great real value, when the pound of beef was regulated at one halfpenny, and that of veal and mutton at three farthings.

Prior to the dissolution of the monasteries, Henry had resolved to convert some of them into episcopal sees, to be endowed with a portion of the lands or the revenues which that dissolution would place at his disposal. Of the projected sees, Westminster was to be one; and on the 17th of December, 1540, the abbey-church was, by letters patent, constituted a cathedral, with a bishop, a dean, twelve prebendaries, and other inferior officers. The new bishop was Thomas Thirleby, then dean of the chapel-royal. The late abbot Benson was, for his ready compliance with Henry's wishes in the change of the abbey, appointed dean of the new cathedral: certain monks became prebendaries, minor canons, and students in the university: the others were dismissed with pensions, decreasing from ten pounds down to five marks. The abbatial mansion was converted into a palace for the bishop, whose annual revenue is variously stated from six hundred to eight hundred pounds. The diocese included the whole county of Middlesex, with the exception of Fulham, the rural residence of the bishops of London. The endowment of the dean and chapter was not completed till the 5th of August 1542, when lands, in various parts of the kingdom, were assigned, of the yearly value of 2598*l.*, out of which, however, the sum of 400*l.* was to be paid for the salaries of five professors of divinity, law, physic, Hebrew, and Greek, in each of the universities. A farther sum of 166*l.* 13*s.* 4*d.* was to support 20 students in the universities; and two masters, with 40 grammar scholars, were to be maintained in the school of Westminster. The new bishopric was, however, but of short duration; for on the 29th of March 1550, bishop Thirleby was required to surrender it to Edward VI., and it was soon afterwards reunited to that of London. Part of the possessions of St. Peter's cathedral were appropriated to the repairs of St. Paul's in London; whence arose the proverb of "robbing Peter to pay Paul." In the edict for suppressing the see of Westminster, no mention was made of the establishment of a dean and prebendaries, &c.; it became consequently a question whether they were to be continued. To remove all doubt on this head, an act passed in parliament, declaring the church still to remain a cathedral, with the former establishment, but within the diocese of

London. On the accession of Mary to the throne, the restoration of the monastery to its pristine condition was carried into effect. The abbot, John Fackenham, surviving Mary, was the only ecclesiastic of his rank who sat in the first parliament of Elizabeth in 1558; and he took the lowest place on the bishops' bench. But on the 21st of May 1560, the monks were again displaced, and the church again rendered collegiate, on a basis very similar to that which had been established by her father, Henry VIII. The last dean of Elizabeth's appointment was the learned Lancelot Andrews, afterwards bishop of Winchester, dean of the chapel-royal, and a special favourite of James I. Since the restoration by Elizabeth, if we exclude the general disorganization of similar institutions, in consequence of the internal disorders which commenced in the reign of Charles I., the collegiate establishment of the abbey-church of Westminster has undergone no material alteration.

Abbey-Church.—Such is briefly the history of the religious establishment on Thorney, to which modern Westminster is indebted for its origin and prosperity. Of this establishment, the church remains in a great measure entire: the buildings appropriated for the abbot and the monks have undergone great alterations; but their general arrangement may still be traced, and they are still allotted for the residence of the persons attached to the service of the church and the dependent school. For a fully detailed description of this celebrated church, of its architectural beauties and defects, of the sepulchral monuments it contains, of the ceremonies performed within its walls, and for a recapitulation of the important transactions connected with its history, recourse must be had to the various works published specially on the subject. This church is a distinguished specimen of that mode of architecture, commonly but absurdly styled Gothic, a term which, however improper, most writers still continue to employ, though no specific style or class of building is defined by it. Erected in the 13th century, when buildings in this style of architecture were well understood, and skilfully constructed, it would doubtless have possessed, if not the spaciousness, at least the light and airy and elegant appearance for which such structures are generally remarkable. But by the introduction of sepulchral monuments, elevated above the level of the choir, many of them magnificent indeed in themselves, but certainly misplaced as far as regards the internal arrangement of the building, that attractive appearance must very early, perhaps from the beginning, have been injured. Owing to those encroachments, it has been necessary to bring forward the present choir much beyond its usual station, not only intercepting the transepts, but advancing a considerable way into the nave, or body of the church. The building consists of a nave and two side aisles, separated by ranges of tall, slender, clustered columns, supporting the roof raised to a great elevation, still further increased in appearance by the narrowness of the space between the columns. The length of the whole edifice within the walls is 360 feet, the breadth of the nave and aisles 72 feet, the length of the cross or transept 195. The insertion of St. Edward's chapel in the choir is particularly unfavourable; for that important division of the building was from the beginning very short: nor is it easy to discover the reason of this deviation from general usage. On entering the great western door, the whole body of the church displays itself to view in a very striking manner. Loftiness, lightness, and elegance, are its marking features; but these features are much obscured, and distracted by the numerous discordant monuments, which fill up the open spaces, and cover the walls. The nave is separated from the choir by a screen; and east of the latter is a chapel,
raised

raised above the level of the pavement, appropriated to the shrine of Edward the Confessor, but also occupied by several monuments to royal and noble persons. At the east end of this is a sumptuous architectural chantry to the memory of Henry V. Still more to the east is the splendid and interesting chapel, called Henry the Seventh's, because begun by him, and founded for his mausoleum. On the north and south sides of the choir are aisles, and also some small chapels, dedicated to different saints.

From the time of Henry VII. little was done, although very requisite, to the exterior of Westminster church, till that of George II., when many parts of it were coated over with stone, and otherwise repaired at the public expence. Some time before this, the two towers at the west end were completed from designs of Sir Christopher Wren, as they now appear. In covering the outside of the church, the rich sculpture, and the statues which formerly adorned the buttresses, could not be restored. Those parts seem now, therefore, unsuited to the highly ornamented building to which they are attached: nor do the western towers assimilate with the style of the fabric to which they belong. The paintings in the great west window were executed in 1735: the window in the south transept was also renewed in 1705. In the interior of the church, the pillars dividing the nave from the side aisles guide the eye to the fine painted window at the extremity of the choir, which, in former times, when the altar-piece was low, must have had a fine effect in giving a lighter air to that part of the building. The altar-piece was brought hither by queen Anne in 1706: it had formerly belonged to Whitehall chapel. The marble columns of the Corinthian order, however elegant in themselves, but ill accord with the style of the structure around them; an incongruity but too often sanctioned in other edifices of the same kind in England. In front of the communion-table is still to be seen, although woefully mutilated, a curious Mosaic pavement of lapis lazuli, porphyry, jasper, serpentine, touch-stone, &c. placed there by abbot Ware in 1272, who brought it from the continent, where he procured the materials during a mission to Rome. The black and white lozenged marble pavement of the choir, was the gift of the celebrated Dr. Busby, master of the school annexed to the church. In the centre of Edward the Confessor's chapel, stands the mutilated body of the shrine, containing, in a wooden case, the ashes of St. Edward; and around the sides of the chapel are ranged the monuments of several kings, queens, and princesses, from Henry III. to Elizabeth, the daughter of Henry VII.; all of which are extremely curious and interesting. In this chapel are preserved the chairs, one very ancient, the other made for the last queen Mary, in which our kings and queens are seated within the choir at their coronation. In the frame of that used by the king is the fatal stone, to the position of which the sovereignty of Scotland, or rather of the Scotch nation, was attached.

The choir of the church, in the form of a semi-octagon, was surrounded by eight chapels, now reduced to seven, by the appropriation of the central chapel to be the porch of that of Henry VII.

The cross-aisles or transepts of the church, as well as the nave, have long been consecrated to the interment of persons in various ways distinguished in the world. The south transept has only an eastern aisle, the west being occupied by part of the cloisters. This transept, named Poets'-corner, contains many interesting memorials of men whose genius and talents in science, literature, and the arts, entitle them to the honourable recollection of posterity. Of these monuments, many are highly interesting as memorials of

eminent characters, and others as specimens of the sculptor's art. No small number of them, however, and those not the least sumptuous and obtrusive, are entitled to no regard on either account, being vast masses of marble devoid of beauty and taste. It is, however, to be remembered, that to be "numbered among the illustrious dead," within the walls of the abbey-church of Westminster, now is and long has been purely a question of finance with the officers attached to the foundation.

Chapel of Henry VII.—In ancient cathedrals and other churches of considerable extent, it was the practice to appropriate to the peculiar service of the Virgin, the chapel situated immediately behind the high altar, and in the eastern recess of the building. Such a chapel originally belonged to the abbey-church; and on its site with some adjoining space, under the same patronage, but now best known by his own name, Henry VII. constructed his magnificent and admirable chapel. When we contemplate this most curious specimen of English architecture, and consider the expence which must have been encountered to complete it, we are utterly unable, on any rational grounds, to reconcile its erection with the acknowledged disposition and character of the founder. In perusing the history of nations, we must be struck with the frequent recurrence of this fact, that men of all degrees, particularly of the highest, have acted on the vain supposition, that, by a single ostentatious act of beneficence or munificence, not unfrequently posthumous, they could acquire immortal fame, and even secure the favour of heaven, however unworthily they may have performed their duty in life. Of this fact, the chapel of Henry VII. stands a memorable example; for in no one act of his life and reign, did that prince give evidence of any one of those feelings from which the construction of this superb structure could be expected to proceed. Of benevolence, however, in a certain sense, no sovereign ever had a better conception than Henry. The vast sums he exacted under this specious title, far exceeded the demands for which they were required: he accordingly amassed great wealth, and at his death his treasury was enormously rich. Towards his end, Henry, sensible of a mis-spent reign, endeavoured to atone for his offences by various charitable works, by bestowing a large sum on King's-college chapel in Cambridge, and in particular by founding, erecting, and endowing his chapel in Westminster. From the elegance and richness of the design, and from the skill and labour necessary to complete it, we are warranted to conclude that the most eminent artists and artificers of the country were employed. The first stone of the new chapel was laid by the hands of abbot John Islip, and other persons of the court, in the presence of Henry, on the 24th of January 1502-3. How much of the work was executed at the king's death, on the 21st of April 1509, is unknown; but most probably the masonry must have been nearly, if not altogether, completed. Towards the finishing of the whole, Henry left, in the hands of the abbot, 5000*l.* with provision for more if required. The superb tomb for the king is particularly described in his will; but a different plan was followed, and the work was finished by his son Henry VIII. The ground-plan of the building consists of a body nearly a square, terminated at the east end by a semicircular part, composed of five sides of an octagon. The extreme length of the whole chapel, including the porch, is 134 feet, and the corresponding breadth 82 feet 6 inches. On viewing the exterior of the building, we are struck by the apparent slightness of the work; for instead of walls, the principal weight and quantity of the whole rests on a few detached piers and lateral buttresses. This peculiar character of
ancient

ancient ecclesiastical buildings, manifests great science and skill in the architects; for to raise lofty walls, and poise ponderous wide-spreading roofs on piers and columns, requires the nicest geometrical accuracy. The sides are supported by five octagonal piers; those of the semicircular end are united to wedge-shaped masses, entering so far into the chapel, as to correspond with the pillars separating the aisles from the nave. The interstices between the external piers are filled by windows of a peculiar plan and great delicacy of workmanship. The roof over the nave rests on perpendicular walls, supported by very slender internal pillars, and is strengthened all around by flying buttresses or semi-arches from the external piers. Within, the chapel is divided by two ranges of pillars into a nave 33 feet 6 inches in width, and side-aisles each 11 feet 3 inches wide. The internal roof is executed in stone, with pendants and numerous ribs. By the advance of the piers in the circular part, that end is formed into five small chapels or oratories; but the side-aisles in their original had no separation from the nave, except the ranges of pillars. They are now, however, unfortunately cut off by a row of stalls on each side, on the line of the pillars, and shooting up with their fretted and frittered canopies as high as the roof of the aisles. What tends to heighten the deformity of these stalls, is the number of gaudy flags of the knights of the Bath, who are installed in this chapel, suspended all around, at once concealing many beautiful parts of the architecture and sculpture, and utterly at variance with the elegance and the design of the edifice. The entrance to the chapel is by a flight of steps to a magnificent gateway, but from its situation dark in itself, and darkening the extremity of the adjoining church. The chief object within the chapel is the tomb of the founder, inclosed by a screen of gilt brass: it is a piece of admirable workmanship, executed by Torregiano of Florence, a rival of Michael Angelo. There also, still in opposition, lie the jealous and vindictive Elizabeth and her unfortunate victim Mary Stuart. Thus in a corner of the abbey-church, a few feet only of earth now separate the once formidable political antagonists William Pitt and Charles James Fox. The bronze figure of Margaret Tudor, mother of Henry VII., is one of the finest pieces of sculpture in the whole building. In viewing this chapel, two subjects always excite regret; the situation in which it stands, and the materials of which the exterior is constructed. Attached to the end of the abbey-church, with which its mode of construction has but a very distant relation; although in itself, if furnished with a suitable front-piece, worthy to be a separate and independent work, it now sinks into a mere appendage. The exterior surface of the chapel is in many parts corroded and consumed; and most of the sculpture is now quite defaced. Some years ago parliament voted a considerable sum of money, to be annually applied to defray the expence of new-casing the whole edifice with Bath stone, and the work has been carried on under the directions of Mr. T. Gayfere, with scrupulous attention to the form and manner of the original workmanship. Beneath the chapel is the vault prepared on the death of Caroline, queen of George II. in 1737, and containing the remains of several members of the present royal family. The cloister of the abbey, still sufficiently entire, and containing numerous sepulchral inscriptions, communicates with the ancient chapter-house, which is of octagonal form, and the roof is supported by a branching central column. It was erected, according to Matthew of Westminster, in 1250, by Henry III. This building, which, till the time of Edward VI., served as a house for the commons of England, is now employed to preserve public

records; amongst them, the celebrated *Liber de Wintonia*, as it was called by the compilers, or *Domesday-book*, as it was not unaptly named by those persons whom it regarded. This work, the most ancient and venerable record, or statistical account, as we now speak, of which this or any other country can boast, was completed about 1086, in the end of the reign of William the Conqueror. (See *DOMESDAY-BOOK*.) In the same chapter-house are also preserved the recorded proceedings of the notorious star-chamber, so called from the star-like ornaments of the roof.

School.—The cloister also communicates with the celebrated school of Westminster, which was refounded by Elizabeth in 1590, with an establishment for the classical instruction of forty boys. After a certain time, the scholars, if duly qualified, are selected alternately for their respective institutions, by the dean of Christ-church, Oxford, and the master of Trinity college, Cambridge. Besides the youths on the foundation, from three to four hundred, others usually receive their education in the school, at the expence of their respective parents.

Parish Churches of Westminster.—The city and liberties are now distributed into ten parishes. Within the city are St. Margaret's and St. John the evangelist's; within the liberties, St. Martin's, St. James's, St. George's, St. Anne's, St. Paul's, St. Clement's, St. Mary's, and the Savoy. St. Margaret's, the original church of the city, is a simple plain structure. It is handsomely fitted up to accommodate the commons of the kingdom on certain solemn occasions; as the choir of the neighbouring abbey-church is allotted to the peers of parliament. One peculiar ornament of St. Margaret's church is a magnificent painted window representing the crucifixion. This very interesting piece was executed in Holland as a present for Henry VII. St. John's church, belonging to a parish formed out of St. Margaret's, furnishes an admirable example of what imagination, unrestrained by judgment and taste, can produce. It ought however to be known, that Mr. Archer, and not sir John Vanburgh, who has been oftener blamed than understood, was the architect of this fabric. St. Martin's and St. George's churches are remarkable for their noble porticoes; but both are so unfortunately, not to say absurdly situated, that it is impossible to have a view of them in any way satisfactory. St. Paul's, Covent-garden, is noted for its simplicity, and its plain, heavy, Tuscan portico. In erecting the latter at the *east* end of the church, where it can be seen, Inigo Jones essayed a bold deviation from established practice; but to change the interior distribution of parts was perhaps beyond his power. The portico therefore stands where no entrance can be opened, for there within stands the communion-table; and the entrance is opened at the *west* end, where there should be, but is not, a portico. The church of St. Mary, like that of St. Clement, is strangely placed in the midst of the Strand, a most public and noisy street; and instead of possessing the simple dignity of a Christian temple, seems rather a model contrived to shew the skill of the architect in comprising the greatest quantity of ornament devoid of utility, within the narrowest bounds. But Mr. Gibbs the architect followed his instructions in adorning an edifice to be so ostentatiously exhibited. He had besides but just returned from Italy, where similar structures abound. It is no wonder, therefore, that, in both the interior and the exterior of the New church of St. Mary, he was led to imitate the buildings he might, as a mere student of architectural design, long have admired.

Besides the churches and chapels of the establishment, Westminster contains places of worship for Christians of all denominations, and of professions the most contradictory, from the mysterious Swedenborgian, who maintains the sole

WESTMINSTER.

and absolute *divinity*, to the simple Unitarian, who asserts the pure *humanity* of the great founder of the Christian religion. French, Swiss, Dutch, and German Protestants, have proper places where the service is performed in their own languages. The Society of Friends or Quakers have a respectable place of assembly in St. Martin's-lane; and various chapels are open for the members of the church of Rome. In Denmark-court, in the Strand, is a well-frequented Jewish synagogue.

Civil and Political State of Westminster.—The first dwellings constructed around the monastery in Thorney, stood on the lands of the establishment, which consequently had full authority to govern the inhabitants. These were rapidly increased in numbers by the privilege of sanctuary granted to the abbey for offenders; but the great causes of the growth, population, and importance of Westminster, were the residence there of the kings, and the transaction of all public business within its precincts. Although the Strand, Whitehall, and a few other parts were inhabited, at the elevation of the abbacy into an episcopal see in 1540, yet the quarter only immediately inclosing the cathedral church was honoured with the title of city. The whole of this quarter was included in the original and ancient parish of St. Margaret; but in order to accommodate the increased body of inhabitants, especially in the southern parts, a new parish was formed out of the old in 1728, and named after St. John the evangelist. All the other quarters of the present Westminster, erected on the liberties of the abbey, are contained within the following eight parishes, arranged in the order of their establishment. St. Clement's Danes, St. Martin's in the Fields, and St. Mary's in the Strand, all of uncertain antiquity. St. John the Baptist's, in the Savoy, also ancient, St. Paul's, Covent-garden, St. James's, St. Anne's, Soho, and St. George's, Hanover-square; the last four all formed within the last 200 years. In designating Westminster in the aggregate, the city and the liberties are necessarily mentioned; but in no respect does any distinctive rank, right, or privilege exist between the inhabitants of those different quarters, who are all equally citizens and members of the same community. On the public change of religion, and the conversion of the abbey of St. Peter into a collegiate establishment of a dean and chapter in 1560, the latter were placed, as to all their civil rights and authority, in the situation possessed by their predecessors; but the sanctuary was, with all other similar privileges, suppressed in the 21st year of James I. The dean and chapter of St. Peter's have, therefore, continued ever since to be the supreme magistrates and administrators of the inhabitants of the city and liberties of Westminster. Since the Reformation, however, the exercise of all civil powers has always been vested in lay persons, elected or confirmed by the dean and chapter. Of this singular and anomalous system of government, which, how applicable soever to the original, seems wholly unsuitable to the modern Westminster, the following are the principal members, as settled by an act of the year 1585:—The first is the high-steward, usually a resident nobleman of distinction (the present is the duke of Northumberland), who is elected by the chapter of St. Peter's; the dean acting as high-steward during and previously to the election. By this principal officer a deputy steward is nominated; but his appointment must be confirmed by the dean and chapter. This deputy acts as a sheriff, holding the court-leet with the other magistrates: he is always chairman of the quarter-sessions of Westminster, which are independent of those of Middlesex. Next in rank is the high-bailiff, nominated on the other hand by the dean and chapter, but confirmed

by the high-steward. He is the returning officer in the election of the representatives in parliament for the city and liberties; and to him all the other bailiffs are subordinate. He summons juries, and has a right to all fines, forfeitures, and strays, within his jurisdiction: he also, on due requisition, calls together and is present in assemblies of the electors, for the purpose of petitioning parliament or the crown, or of transacting any other public business in which they are all concerned. The high-constable, chosen at a court-leet of the magistrates, has all the other constables under his superintendance. In addition to these officers, sixteen householders, styled burgeses, are chosen, with their assistants out of the different parishes. These resemble the aldermen and common-council of London, each having a particular ward or district under his inspection; and of their number two head burgeses are chosen, who, at the court-leet, sit next to the high-bailiff. The inhabitants of Westminster form no corporation, nor do they possess as such any exclusive privileges; neither do any companies of trade or profession exist within the jurisdiction. The various courts of justice belonging peculiarly to Westminster are, 1. The court of the duchy of Lancaster, a supreme court of record, held in Somerset-place, for deciding by the chancellor of the duchy all matters of law or equity concerning the estates belonging to the county-palatine of Lancaster. 2. The quarter-sessions of the peace, a court of record, held by the justices of the peace at the Guild-hall, near the abbey-church, for all trespasses, &c. committed within the city and liberties. 3. The court-leet, held by the dean, or his steward, for choosing parochial officers, preventing and removing nuisances, &c. 4. Courts of requests, or of conscience, as they are called, for deciding without appeal by commissioners, all pleas for debt under forty shillings. 5. Courts of petty-sessions, held every lawful day at the offices in Bow-street, Marlborough-street, and Queen-square, for matters of police, misdemeanor, or offence. 6. To these must be added the court of St. Martin-le-grand, in London, but belonging to Westminster. The jurisdiction of the dean and chapter of St. Peter's, widely extended as the liberties are, is not confined to their bounds. In the very heart of London, under the walls as it were of St. Paul's, is the precinct, as it is termed, of St. Martin-le-grand, an integral part of Westminster, and wholly independent of London. This precinct took its name from a collegiate church founded in 1056, dedicated to St. Martin and qualified *le-grand*, on account of the great privilege of sanctuary conferred on it. By Henry VII. it was bestowed on the abbey of St. Peter; but on the surrender to Edward VI. it was pulled down, and houses were built on the ground. Being let out to strangers not freemen of London, they claimed the privileges before enjoyed by the canons of the suppressed institution. Those claims produced many contests which were never definitively settled; and the exemption of St. Martin's precinct from the jurisdiction of London seems now to be established, rather by long-continued usage than by any regular or authoritative declaration of right. This small precinct (a term in London signifying specifically a subdivision of a ward) consists of one short street of its own name, leading north from the east end of Newgate-street to the beginning of Aldersgate-street, and a few lanes and courts on each side. In this precinct persons not freemen of London, exercise their several trades or professions without controul; the inhabitants also concur in the election of representatives for Westminster, in the same way with those who actually dwell within that city. A very material change is now (1818) in progress in St. Martin-le-grand. The chief office of the general post, domestic and foreign, situated in Lombard-street, in Lon-

don, has long ceased to be either central in position or commodious in distribution, for the prodigious business transacted in it. After many attempts, chiefly on the part of the inhabitants of the west end of the town, where many of the principal men of business reside, parliamentary sanction has at last been obtained for the erection of a new post-office, properly adapted, in situation and internal arrangement, to the purposes of the establishment. The situation selected is in St. Martin-le-grand; and the necessary preparations in removing houses and clearing the ground, have made considerable progress. The expense of this enterprise must be great; but the edifice may be rendered highly ornamental as well as useful to the metropolis. Mr. Kay is the architect. The jurisdiction of the dean and chapter of Westminster extends also over some places in Essex, on that account independent of the diocesan bishop of London, and even of the metropolitan of Canterbury; for while the Roman Catholic religion prevailed, the abbey was immediately under the pope. If the jurisdiction of the abbey thus extended over places remote from its bounds, it on the other hand comprehended within its bounds, a district exempt from its jurisdiction. This is what is commonly called "the liberties, or the duchy of Lancaster." The district comprehends all the south side of the Strand, from the Temple to Cecil-street, with nearly the same extent on the north side. The palace and district of the Savoy having been a part of the possessions of the house of Lancaster, which were separated from the crown by Henry IV., that part of the Strand belonging to the Savoy became a district or liberty of itself. It has a supreme court under the chancellor of the duchy of Lancaster, as already mentioned; and formerly no inhabitant of this district voted for the representatives of Westminster. But at the election in March 1795, those of the duchy-liberties who lived within the parishes of St. Mary in the Strand, and St. Martin's in the Fields, were admitted to give their suffrages. Until after the dissolution of the abbey, Westminster sent no representatives to parliament; being virtually represented by the abbot, who sat with the bishops in the house of peers. In the records of the last parliament of Henry VIII. no mention appears of any summons or returns relative to Westminster, Peterborough, or any other abbey-town. The first parliament of Edward VI., therefore, is that in which the members for Westminster began to take their place. The two representatives of the city and liberties are elected by the inhabitant householders, or those paying scot and lot, who are now estimated at about 17,000; the number being considerably increased by the enlargement before-mentioned in 1795. The elective franchise being thus widely diffused among all ranks of the inhabitants, and the popular favour being commonly in the inverse proportion of that of the court, one if not both of the representatives of Westminster may generally be expected to be decidedly hostile to the measures of the existing administration. So well is this understood by ministers, that, to have at least one member favourable to their views, they have frequently encouraged some distinguished naval commander to offer his services to the electors.

Having for many years been the ordinary residence of the sovereign, Westminster has of course contained the principal departments of every branch of legislative and executive administration. The parliament, originally ambulatory and attached to the person of the king, was rendered stable in Westminster on the confirmation of Magna Charta by Henry III. in 1216. Long before that period, the royal palace was erected adjoining to the abbey; and as in those early times justice was often administered by the king in person, or in his presence, the various courts of judges were of

course established in or near his residence. When the palace of Westminster ceased to be occupied by the monarch, and Henry VIII., in 1512, transported his court to Whitehall, the parliament and the judges still retained their original station; but the executive branches of administration, relative to financial and military affairs, accompanied the court. Hence we see those departments all established in what is still called Whitehall; although the king has long ceased to reside in that quarter, and that a very small portion of the old palace is either occupied by public offices, or even in existence. Hence also it is that all public acts of government are dated from Whitehall. From the prodigious multiplication and subdivision of all public affairs relative to justice, finance, and military and naval operations, the details of various branches have necessarily been carried on in other convenient quarters of the metropolis. Such are the Temple, Lincoln's-Inn, Guildhall, the Bank, the Custom-house, the Excise-office, the Tower, &c.; still it is in Westminster alone that the general arrangement of the whole is conducted.

Public Buildings.—Of the ancient residence of the kings of England in the vicinity of the abbey of Westminster, the name, the general position, and a few mutilated apartments, are all now remaining. According to a survey and plan of the whole buildings and vestiges of this palace, it extended along the bank of the Thames from north to south, and then turned westward near to the buildings of the abbey. Of the general arrangement, it is impossible to discover more than that the walls and foundations seem to have been all parallel to the corresponding walls of the present great hall, the only part still remaining in its original state. Composed of parts erected at different periods, no balance or symmetry of plan seems to have been regarded in their distribution.

Westminster Hall, memorable in itself as a building, as the scene of many important transactions, and for the uses to which it is applied, was erected by William Rufus, or William II., about 1097, as an appendage to the old palace, or a part of a new project. Having suffered much from accidental fires, as well as from the lapse of time, the hall, just three centuries after its construction, was completely restored by Richard II., who heightened the walls, altered the windows, adding a new roof, and built a stately gateway. The hall is a vast parallelogram, standing north and south, in length, within the walls, 249 feet, and in breadth 66 feet, not 74, as is generally stated. The walls, although massive and plain, are externally strengthened by buttresses. The roof, rising to a high pitch, is ingeniously and firmly constructed, not of Irish oak, as usually said, but of chestnut brought from Normandy. This room is said to be of greater magnitude without pillars than any other known. In this hall parliaments have been held; Richard II. was deposed in it in 1399, and for many ages it has been employed in the coronation-feasts of the sovereigns. In it assembled the court for the trial of Charles I., in January 1649. It is still the place of inquiry, before the house of peers, into the conduct of persons impeached by the house of commons. In the middle of the right or west side of the hall, is an opening into the court of common pleas. The south end of the hall is occupied by wooden structures, to contain on the right-hand the court of chancery, and on the left the court of king's bench; so called because the king in ancient times actually sat, as he is at present asserted, by what is styled a legal fiction, actually to sit, on the bench to administer justice. Between these two courts stairs conduct to the apartments occupied by the two houses of parliament. That employed by the peers was towards the south end of the old palace; but on account of the additional number of 32 peers entitled

bled to seats on the union with Ireland, over and above the unexampled augmentation of the peerage in the present reign, their meetings were transferred to what was the court of requests; so called because the masters of the court, in ancient times, received the requests or petitions of the people, and gave their opinions on the subjects. This room, considerably larger than the former, is also within the old palace; and is now ornamented with the celebrated tapestry, representing the discomfiture of the Spanish Armada, or fleet and army, destined for the invasion of England in 1588. At the upper end of the room is the throne, a highly enriched arm-chair; and at the lower end is an open space, termed the bar. The commons of England, when they formed a separate body from the peers, were, by an agreement with the abbot of St. Peter's, allowed to meet in the chapter-house already mentioned. But when, at the Reformation, the establishment of the collegiate chapel of St. Stephen in the old palace was suppressed, to that place their meetings were transferred by Edward VI. This chapel, originally constructed by king Stephen, was rebuilt by Edward III. in 1347. The commons, before the union with Ireland, were accommodated within the chapel; but their number being by that measure augmented from 558 to 658 members, it became necessary to enlarge the place of assembly. At the east, or upper end of the room, is the speaker's chair; before it is the table with the clerks, and at the bottom is the bar. The seats for the members rise one behind another, as in a theatre. Those on the floor, on the speaker's right-hand, are called the treasury-benches, and occupied by the members of administration: the bench in front is usually occupied by the leading members of the opposition. St. Stephen's chapel, highly adorned by Edward III., suffered greatly by its first adaptation for the commons; but much more by the late alterations. By removing the wainscot, a great part of the ancient decorations was disclosed, and a very important fact in the history of the fine arts was, for the first time, ascertained. On the 11th of August, 1800, was discovered a series of sculpture and painting, the latter exhibiting portraits, scripture-scenes, and other decorations, interesting in themselves, and peculiarly so as specimens of the state of the arts, as they existed nearly five hundred years ago. It has been usual to ascribe to John Van Eyck, of Bruges, in Flanders, the invention of painting in oil-colours, in 1410. This opinion has, however, of late years, been much invalidated; by the discovery in St. Stephen's chapel it is completely overthrown. From original records of the expences incurred in the construction and decoration of that building, it now appears that the renovation was begun in the fourth year of Edward III., or about 1329, and not in 1347, as stated by Stowe and others: that the painters had not begun in 1345, but were at work in 1350, and ceased to be mentioned in 1364: that those who painted on glass had begun in 1350, and finished in 1352: that the paintings were unquestionably in oil: and that, of seventy-six painters employed in the chapel, the whole, with the exception perhaps of two, and they not the masters, were natives of England. From these authentic documents it is therefore fully ascertained, that *pictures*, in the usual sense of the term (not *house-painting*), in *oil* were executed in Westminster palace in 1350, or sixty years before Van Eyck's supposed discovery of the art. But the same genuine records go still farther back: they prove oil to have been employed in painting pictures in the chapel before the rebuilding by Edward III.; that is, in the 20th year of Edward I., or in 1272, which was one hundred and eighteen years prior to Van Eyck. (See PAINTING.) Under the old house of

lords are the cellars which were prepared for the famous powder-plot, of the 5th of November, 1605.

Whitehall Palace.—This royal mansion occupied a considerable space on the bank of the Thames, including Privy-Garden, and extending to Scotland Yard, stretching out in breadth from the river quite across the street still called Whitehall into St. James's-park. It was originally the property of Hubert de Burgh, earl of Kent, and grand justiciary of England under Henry III. The situation was low and marshy, owing to the concurrence of the branch on the west of Thorney island with the main channel of the Thames. In 1248 the palace belonged to the archbishops of York, who possessed it until, on the fall of cardinal archbishop Wolsey, it was, in 1529, seized, with his characteristic love of justice, by the insatiable Henry VIII. Possession being obtained, many alterations were made in the building, of which a portion, commonly called the Cock-pit, adjoining to the Treasury, still exists. Falling into decay, James I. resolved to rebuild Whitehall in a suitable manner; and for such a design the spacious ground between the Thames and the park, and commanding both, offered every facility excepting that of elevation of ground, without a proper degree of which dignity is hardly attainable in architecture. Of the magnificent, although in many parts faulty, project of Inigo Jones, prepared for the intended work, one portion only was executed. This is the Banqueting-house, so called from its succeeding, in destination as in scite, to a part of the old palace appropriated to royal entertainments. The present edifice, one of the few specimens of noble and regular architecture in the metropolis, consists of two stories, on a rustic basement, ornamented with Ionic and Corinthian columns and pilasters. This edifice, containing seven windows on a floor, was only one of the angular pavilions of the intended grand structure. It is sufficiently enriched, but not overloaded with ornament; and being constructed on a scale of very large dimensions in the parts, had the whole, even with all the defects of the project, been carried into effect, no sovereign in Europe could have exhibited a place of residence to be compared with that of the king of Great Britain. Magnitude of parts was in that project held to be indispensable for grandeur of effect. The interior of the Banqueting-house has long been converted into a royal, and lately into a military chapel; adorned, as is still most incongruously imagined, with trophies of war. The ceiling is peculiarly worthy of observation, being the production of the splendid pencil of Rubens; exhibiting the allegorical history of his patron, James I. This masterly performance ought to have dissuaded the advisers of George I. from converting the room into a place of Christian worship; for "its contents are in no way akin to devotion; and the workmanship is so very extraordinary, that, in beholding it, the spectator must either possess an uncommon measure of zeal, or be utterly destitute of skill and taste, who can attend to any thing besides." From a window of the Banqueting-house the unfortunate Charles I., unfortunate in living in times when the art of managing parliaments was either unknown, or perhaps thought unworthy of a prince, passed to the scaffold erected in the public street in the front of his own palace. In a court behind the building stands one of the small number of public statues of the metropolis meriting examination. It is the work of Gubbins, and exhibits James II., indicating, as he would do in his destined situation, with an air and attitude full of expression, the spot where his father suffered. At no great distance, on the former scite of the cross in the village of Charing, is erected another fine equestrian figure of Charles himself.

St. James's Palace.—That the sovereign of the British empire was far less suitably lodged in his capital than are numbers of his subjects, has by foreigners been often remarked, and by natives been sometimes converted into a compliment to the sovereign and to the nation. But the fact is, that St. James's palace was in its origin an hospital, of part of which Henry VIII. availed himself to construct the present buildings, as an appendage to the palace of Whitehall, with which it was connected by St. James's park. Having been allotted for the residence of the princess, afterwards queen Anne, and her husband George of Denmark, St. James's has ever since continued to be occupied for court or state purposes. The buildings are neither grand nor regular: the front, overlooking the park, has alone a certain air of dignity: and the state apartments, although they contain nothing peculiarly magnificent in the furniture or the decorations, are commodious and handsome.

Connected with this palace is the park of the same name, ornamented with a long canal in the middle, and with broad walks, separated by rows of trees on the sides, the only species of improvement of which its flat situation is well susceptible. Near the centre of the canal, a wooden bridge, in the Chinese style, has been built across the water. On the north-west of St. James's-park is an open space, called the Green-park, capable, from its elevation and variety of ground, of much greater improvement: but its principal recommendation is that, being in fact a wide extended green field, it furnishes a delightful promenade in all directions, and welcome relief from the hard pavement of the streets.

Buckingham-House.—This edifice, now settled on the present queen in lieu of Somerset-house, and hence called the Queen's palace, possesses peculiar attraction, as much from its very favourable situation, as from its history. It was built by John Sheffield, duke of Buckingham, about the year 1700, and its gardens were adorned with terraces, canals, &c. The building is of brick, and most of the apartments are small. In this palace for several years were held his majesty's levees, while his health permitted his appearance. Annexed to the palace are an octagon and other apartments, containing the king's library, rich in various works of value, particularly in early editions of books. Interior views of the chief rooms, with an ample history of this edifice, &c. are given in Pyne's History of the Royal Palaces.

Carlton House, the residence for a number of years of the prince of Wales, regent of the united kingdom, as formerly of the princess dowager of Wales, his majesty's mother, occupies a situation in between Pall-Mall and St. James's park. The chief front towards the street presents the singular incongruity of a lofty and highly enriched Corinthian portico, giving entrance into a low rusticated edifice. Between the house and the street is a court-yard, bounded by a low wall, sustaining an open colonnade, with an entablature. The interior has undergone many changes, and is fitted up in the most costly and sumptuous manner. The library, conservatory, and the armoury, are very fine and splendid. The work just referred to contains several beautiful prints of the different rooms; also a particular account of the house and its contents.

The ancient palace of *Somerset-house* has now disappeared, being superseded by the magnificent structures composing Somerset-place. Of the Savoy a few portions still exist, but much changed from their original destination; and in a few years, perhaps, even the whole may be effaced.

The plan of Somerset-place, as formed by sir William Chambers, was to comprehend within one vast edifice pro-

per apartments for transacting many branches of the national business; and to this purpose, incomplete as it is, it is now applied. Besides these departments, Somerset-place contains handsome suites of rooms for the Royal and Antiquarian Societies, and for the Royal Academy of the Fine Arts. The front towards the Strand, of regular architecture, is spacious and lofty; but, on the whole, having the air, as in fact it is, of the entrance to a structure of great extent and magnificence. The front consists of nine arcades on the ground-floor, the three in the middle forming the entrance, by three colonnades supported on coupled columns. Above the basement is a range of ten Corinthian semi-columns extending over two ranges of windows. Above the three centre windows rises an attic, with statues. The whole is, however, a very great work, and cannot fail, when beheld from the river, or the new bridge adjoining, to have a powerful effect on the spectator. Situated on a rapid descent to the river, the labour and expence of raising the square to the level of the street has been prodigious; and the skill shewn in constructing the whole edifice well merits admiration.

Part of the old palace of Whitehall, as already noticed, may be traced in the building usually called the Treasury; but that part which faces the parade in the Park is comparatively modern, and constructed in a style announcing strength as well as dignity and accommodation for business. Close to this edifice stands that called the Horse-Guards, because a party of that class of troops daily do duty there. Constructed on a plan and elevation intended to recal the idea of an antique fortress, it contains the chief departments of business comprehended under the title of the War-Office. The neighbouring office of Admiralty, spacious and lofty, is greatly indebted to the screen erected by the Adams, by which the enormous portico is brought to bear apparently some degree of proportion to the building.

The theatres of Drury-lane, Covent-garden, the Hay-market, and Opera-house, have been all noticed in the description of London. See LONDON.

At no great distance from the magnificent pile of Somerset-place, and similarly situated over the Thames, stands an extensive range of buildings called the *Adelphi*. The erection of these, a vast enterprise for private individuals, is the work of the celebrated architects, Messrs. Adam. The terrace, which commands the river and surrounding buildings, and the streets and buildings, are elevated on arcades rising from the edge of the water, adapted for warehouses, and opening into roads leading up to the Strand. In the Adelphi is a handsome edifice, belonging to the Society for the Encouragement of Arts, Manufactures, and Commerce. The great hall exhibits a series of paintings, unique in modern times, by James Barry. An establishment of a peculiar character has lately begun to appear on the bank of the Thames, a short way above the extreme buildings of Westminster. This is the *Penitentiary*, designed for the punishment, employment, and reformation of offenders of secondary criminality. When, by the emancipation of the British colonies in North America, transportation of offenders to that country necessarily terminated, the plan was adopted of removing them, to contribute to the colonization of the newly-acquired territories in the Asiatic seas. The system, however, when applied to cases of limited expatriation, being highly objectionable, the scheme of the rising establishment has been approved, and its execution begun. The criminals are confined in circular buildings, so constructed that the overseers may, from a central situation, unseen, observe every room. The edifice will, when complete, form externally a hexagon,

consisting of six of these circular divisions; the whole encompassed with a wall, inclosing 18 acres of ground, and calculated to contain altogether from 1000 to 1200 prisoners. Some of them are already placed, and the beneficial effects of the institution on their general conduct has already been very perceptible. As a part of Middlesex, the proper prisons for criminals are those belonging to the county; but in Tothill-fields is a bridewell for the detention and temporary punishment of petty offenders, under the charge of the magistrates of the city and liberties. The charitable establishments of Westminster for the education and maintenance of youth and the consolation of age, for the relief of disease and accidental calamity, are much more numerous and useful than splendid. St. George's and the Middlesex hospital, (not, however, properly within the town,) the Westminster infirmary, &c. are excellent institutions, superintended by medical gentlemen of the highest professional reputation. Of the distinguished private mansions of noblemen and others, it is impossible here to do more than point out a few of the most remarkable. Among these are Northumberland-house, the only residence now remaining of our ancient nobility in the Strand; the duke of Marlborough's in Pall-Mall, erected by the nation for the great duke John; the duke of Norfolk's, St. James's square; earl Spencer's in St. James's place; Burlington-house; the duke of Devonshire's and earl of Egremont's in Piccadilly; the marquis of Lansdowne's in Berkeley-square; the earl of Chesterfield's in South Audley-street; earl Grosvenor's in Upper Grosvenor-street; the marquis of Anglesey's in Burlington-street; the marquis of Stafford's, Cleveland-house. These are some of the best, as far as the exterior is concerned; but many others might be noticed highly deserving of attention, particularly for the admirable paintings by the best masters with which they are enriched.

Bridges.—It is a remarkable fact, that, great and important as Westminster is, until the construction of the noble bridge of its own name, of 15 arches, and in total length 1223 feet, completed in 1750, it possessed no other mode of communication across the Thames than by ferries, or by the embarrassed circuit of London-bridge. The opening of Blackfriar's-bridge was certainly a great accommodation for an extended portion of the town; but still something more was wanted, in a space between those bridges of no less than 3100 yards, or one mile and three quarters, of a most populous and active metropolis. About mid-way of this interval was opened, on the 18th July, 1817, a new bridge, leading from the Strand between the Savoy and Somerset-place, called the *Strand or Waterloo* bridge: it is a structure of a novel description in this country. The idea of it is not, however, new, having been frequently suggested, particularly by Gwyn in 1766. (For a particular description of this bridge, and the dimensions of its various parts, we refer to the article *WATERLOO*.) The road-way is strictly horizontal on the level of the street in the Strand, but much above the surface of the Surrey shore, to which it descends by a long and gentle slope. Each pier, as in Blackfriar's-bridge, is externally ornamented with two Tuscan columns supporting a square projection. The bridge was opened on the anniversary of the horrible carnage of Waterloo, and from this event it has been attempted to give it a name. In this case, however, as in that of what was formerly styled Pitt's-bridge, in London, in 1760, the public, unable to discover even the most distant relation between the structures and the proposed appellations, know them only, as they must naturally do, by their situation, as Blackfriar's and the Strand bridges. This admirable work

does great honour to the engineer and architect Mr. John Rennie, and to the judgment of the managers of the enterprise; and is, all circumstances of position, form, and materials considered, without a parallel in Europe. Besides the Strand-bridge, another of a different kind has lately been constructed over the Thames, just a mile above Westminster-bridge, leading over from Tothill-fields to Vauxhall, and thence properly named *Vauxhall-bridge*. The architect, Mr. Walker, has divided the breadth of the river into nine apertures, covered by frames of cast-iron, resting on stone piers. The road is not horizontal, but forms two gently inclined planes, meeting in a very obtuse angle in the middle. The length of this light and elegant bridge is 809 feet. A third bridge, not indeed immediately connected with Westminster, but of great importance to the metropolis, is now in progress. This is the Southwark-bridge, commencing between that portion of the town and the city of London, on the line of Queen-street and King-street to Guildhall. This extraordinary structure, designed also by Mr. Rennie, consists of three grand arches of cast-iron, in segments of very large circles: the centre arch 240 feet in span, and the two others of 210 feet, each. To enable the reader to form a comparative idea of the bridges now mentioned, the following dimensions of some other remarkable bridges are subjoined. London-bridge, (see *BRIDGE*.) consists of 19 very unequal arches; Southwark-bridge (the iron part), 730 feet long, and of three arches; Blackfriar's-bridge, 995 feet long, of nine arches; Strand-bridge, 1280 feet long, of nine arches; Westminster-bridge, 1223 feet long, of 15 arches; Vauxhall-bridge, 809 feet long, of nine arches. On the continent, the most remarkable structures of this description are the celebrated horizontal bridge over the river Loire, at Tours, in the west of France, in length 1335, and consisting of 15 elliptic arches; the bridge over the Moldaw, at Prague, in Bohemia, 1700 feet long. These, however, are all far outdone by the antique bridge over the Rhone, at St. Esprit, in the south of France, consisting of a multitude of small arches, supporting a very narrow road-way, extending in all nearly to 3000 feet. This bridge has the peculiarity, that, instead of being straight, it is composed of two lines forming an obtuse angle, turned against the current, as if the better to withstand its violence.

Literary and Scientific Institutions.—These have already been noticed in the article *LONDON*, to which the reader is referred. It will always be a peculiar honour for the British nation in general, and to the metropolis in particular, that, with very few exceptions indeed, all those valuable institutions for the promotion of learning, science, and the arts, which add so much splendour to the capital, owe their origin, their maintenance, and their reputation, to the voluntary exertions, personal and pecuniary, of private individuals. The two principal exceptions in London and Westminster are the *British Museum*, and the *Academy of Painting, Sculpture, and Architecture*; but from their nature, without public aid, neither of these institutions might ever have been established. (See *MUSEUM*.) The British Museum is in regular and rapid progress, in the acquisition of stores of high importance in the departments of natural history, literature, and art, to which it is devoted. The *Elgin marbles*, or the venerable monuments of Grecian sculpture, rescued by the earl of Elgin, during his embassy at the Ottoman porte, from barbaric neglect and destruction, in their original position in Athens, are objects of attraction and importance unparalleled in Western Europe. Of the British Museum, in general, it is but justice to observe, that, in no

similar establishment, can more attention be shewn to facilitate the researches, literary or scientific persons, of all who resort to the treasures it contains.

The population of Westminster very sensibly fluctuates, according to the season of the year. From October to July, while the parliament is assembled, the courts of law are sitting, and the places of amusement are open, the town is fully inhabited. During the other months, even those whose business is still transacted in town retire to their villas or quarters, in the surrounding villages and country. A hundred years ago, the inhabitants were computed, but surely overrated, at 130,000: by the last returns to parliament in 1811, they amounted to 62,085, occupying 17,555 houses.

The books examined for the foregoing account, and to which the reader is referred for more minute particulars, are, *Antiquities of Westminster*; the literary part by J. S. Hawkins, esq.; plates from drawings by J. T. Smith; 1 vol. 4to. 1807. *The History of Henry VII.'s Chapel*, by J. Britton, with plan, views, elevations, &c.; in vol. ii. of *Architectural Antiquities of Great Britain*. *The History and Antiquities of the Abbey Church of St. Peter at Westminster*, 4to. 1818, &c., by E. W. Brayley; with numerous plates from drawings by J. P. Neale. *The History of the Abbey Church of St. Peter's, Westminster, its Antiquities, and Monuments*; in 2 vols. 4to., with 63 engravings; published by Mr. Ackermann. *An Inquiry into the Time of the first Foundation of Westminster Abbey, &c.*, by R. Widmore, 4to. 1743. Also, *The History, &c. of the Abbey Church*, by the same author, 1751. *Westminsterium, or the History and Antiquities of the Abbey Church of St. Peter, Westminster*, by John Dart; 2 vols. fol. 1723. The general histories have been already referred to in the article LONDON.

WESTMINSTER, a town of Massachusetts, in the county of Worcester, containing 1419 inhabitants; 55 miles N.W. of Boston.—Also, a post-town of Vermont, in the county of Windham, containing 1925 inhabitants; 18 miles N. of Brattleborough.—Also, a town of Maryland, with a post-office; 26 miles N.W. of Baltimore.

WESTMINSTER-Hall, an island in the straits of Magellan, situated to the N.E. of Cape Pillar. S. lat. $52^{\circ} 34'$. W. long. $76^{\circ} 16'$.—Also, an island in the Mergui Archipelago. N. lat. $10^{\circ} 42'$.

WESTMORE, a town of the state of Vermont, in Essex county, containing 71 inhabitants; 65 miles N. of Norwich.

WESTMORELAND, WESTMORLAND, or *Westmoreland*, a northern county of England, surrounded by parts of Durham and Yorkshire to the N., N.E., and E.; by Lancashire to the S. and to the S.W.; and by Cumberland on the W. and N.W. The greater part of the boundary line is artificial; but at the S. and S.W., rivers and lakes constitute natural lines of demarcation. This district is supposed to have derived its name from being a western moorish country; perhaps it was the land of the moors or lakes in the west. It formed a part of the territory of the *Brigantes* in that district occupied, according to Richard of Cirencester, by the *Voluntii* and the *Sistuntii*. The *Brigantes* were the principal inhabitants of the Roman province *Maxima Caesariensis*; and during the heptarchy were included in the extensive kingdom of Northumberland. In the time of Edward the Confessor, this kingdom was divided into six shires, of which one was called "*Appulbifchire*, to which belonged the land of Westmoreland." In this division, however, Kendal and its district were not included; for

long after the Norman Conquest, they were reckoned to be long to the hundred of Lonsdale, in Lancashire. Of the Roman establishments in Westmoreland, many noticeable vestiges are to be found in stations, forts, roads, inscriptions, and other remains. Among the stations, or towns, may be mentioned *Amboglana*, a name supposed to be still preserved in Ambleside, at the N. end of Windermere; but Horsley places *Diſis* at that town. At any rate, bricks, urns, coins, and other relics, sufficiently prove it to have been occupied by the Romans. *Vertera*, another Roman station, was situated where now stands Brough-under-Stanmore, a name announcing an ancient fortification. *Aballaba* seemed naturally to have given rise to the modern name of Appleby; but no Roman remains have ever been found at that place, although it be undoubtedly of considerable antiquity. *Galacum* is by Camden placed at Whelley; but by later writers near Appleby. *Brovacum* is probably Brougham castle, near Penrith. This station has often been confounded with *Brogonaca*, of which remains exist in Kirkbythore. This station Whelley or Whelp castle lies in the middle of the village, and is commonly called High Burwens. It occupies an advantageous position; the extent from west to east is about 160 yards. The foundations of the vallum are very plain. Among the inscriptions found in it is one *Fortuna Servatrice*. A branch of the great Roman road, called the Watling-street, passed through the county from Stanmore to Brougham castle; and until the modern turnpike-road was made, the former was very conspicuous almost all the way. Between Brough and Kirkby, parts of it are still to be observed; keeping, as was the practice of the Romans, a straight course, regardless of difficulties. This road measured about six yards in width, and is described to have been formed, in many places, by three courses of large square stones. Near the northern border of the county, and not far from Kirkbythore, is a large encampment, attributed to the Romans, and measuring about 300 yards in length, by 150 in breadth. It is represented as having twelve entrances, with bastions to each; but this is improbable. Some topographers describe a few of the antiquities of the county as of Celtic, or Druidical origin; particularly "a sort of Druidical place of worship near Shap." Maybrough castle, and Arthur's Round Table, near Penrith, are referred to the British era. There are also several cairns, or heaps of loose stones, in the county. At Kirkbythore, a Roman road, called the Maiden-way, branched off, and passing over the lower end of Cross-fell, terminated at Caer-vorran, in Northumberland. Roman inscriptions have been found in various parts of the county. One in particular was discovered at Kirkbythore, inscribed *Deo Belatucadro*, a local divinity probably of the original Britons. In 1739, at the same place, was found a stone inscribed *Jovi Serapi*. In the manor of Milbourn was found an altar to *Silvanus*, within a round fort surrounded by deep ditches, called Green-castle. This county is divided into the two baronies of Kendal and Westmoreland, the latter of which is occasionally called the barony of Appleby; and these again subdivided into the four wards of East, West, Kendal, and Kirkby Lonsdale. In ancient times, the Kendal barony was deemed part of the county of Lancaster. In the Domesday survey, an account is taken of some places in the barony of Kendal, with some neighbouring property in Lancashire and Yorkshire; but the Westmoreland district is unnoticed in that record, and thence supposed to have been uninhabited and waste at the time of the Conquest. The Kendal barony is in the diocese of Chester, and consists of two rural deaneries; whereas the other barony is within the diocese of Carlisle, and consists of one

WESTMORELAND.

one rural deanry. The whole county contains only thirty-two parishes. According to the census of 1811, these contained 9064 houses, and 45,922 inhabitants.

The general appearance of Westmoreland is marked with some of the strongest features in nature; immense tracts of mountains, beautiful but contracted valleys, extensive lakes, and large rocky districts, which contain many high, steep, and bulging crags. The county is not only encircled with mountains, but the greatest part of its interior surface is swelled into hills. A long range of heavy-looking hills bounds the eastern side of the county; in front of which is an extensive tract of tolerably level ground. The rest of Westmoreland is almost wholly hill and dale. The farm-houses and those of the small villages, covered with blue slate and whitened with lime, are seated about the bases of the hills, with their small irregular fields spreading up the sides of the mountains, and almost universally divided with stone-walls. This last circumstance gives the country a naked appearance; but the numerous tracts of woodland interspersed tend to enliven the scene. Every dell or hollow has its little brook, and the smallest of these are plentifully supplied with fish. Several low heathy commons are seen towards the eastern side of Westmoreland; and the western part is characterised by high rugged prominences, and even some rocky plains, small coppices, and a large extent of low flat peat-mofs; on the north, the fine woods about Lowther add a striking feature to the landscape. Such are the brief but general outlines of the picture: we proceed to particularise some of its peculiar characteristics, the most prominent of which are its *Mountains*. These are provincially called *fells*, of which the following are the most noted.

Farlton-knot, near the borders of Lancashire, is a very protuberant lime-stone rock; from the Kendal road, near Burton, it is said to have very much the appearance of the rock of Gibraltar.

Whitbarrow-scar is also a very high rock, and in some parts presents a perpendicular face of solid lime-stone. It rises its grizzly front between Milnthorp and Cartmel. The high road leads along its base, whence it presents a grand, and in some places a tremendous aspect.

Langdale-pikes, in the western corner of the county, are conical hills of great height, with pyramidal rocky tops, and are situated in the interior parts of a very mountainous district; their sides and bases are verdant, and have formerly been covered with wood.

Hill-bell is also a high conical-topped mountain, about four miles east from Amblefide.

Harter-fell, High-freet, and Kidsey-pike, are stupendous heights, within a few miles of the southern end of Haws-water. From the top of High-freet, thirteen lakes, and the sea in several directions, may be seen.

The chain of hills on the east, which is continued north and south through other counties, presents a heavy and regular appearance; and they have mostly mossy and heathy tops, except two or three conical green hills opposite Appleby. They are in general picturesque; some with abrupt declivities, or rocky fronts, form high precipices, or in bulging shattered crags project over the vales in a frightful manner; while others shew smooth, verdant, and swelling surfaces, beautifully spotted with flocks of sheep and herds of cattle.

There are few Caves in Westmoreland; one, however, is to be found at Dun-fell, bordering on Cumberland, and is of considerable extent. So intricate are the different passages and chambers of this capacious cave, that the Rev. William Richardson is said to have been seven hours in examining its varied parts. He describes the roof in some

parts to resemble pointed arches, in others flat surfaces: he found in some places the *stalactites*, and pieces of *rhomboidal spar*. He travelled nearly two miles in a right line, and discovered evident marks of some of the chambers having been filled with water. The highest part of the vault is rather more than 25 yards; the breadth in some places about 150 yards; in other parts there was scarcely height sufficient to creep through the hollow. Some other visitors have mentioned the astonishing lustre of the spar with which these vaults are encrusted. Nicholson and Burn, in their "History of Westmoreland," mention three pits, one of which is generally considered unfathomable. In the season of salmon smelts, these pits abound with those smelts, when they are to be seen also in the river Kent, which induces a belief that they arrive from thence in subterraneous passages.

Rivers.—Although the rivers or streams, (provincially called *becks*,) are numerous, they are but small, and mostly rise within this district. Only three of these are sufficiently important to retain their original names from their sources to the sea. These are, the Eden, the Lune, and the Kent, or Ken. The first springs in Mallerstang, and runs north, and having received in its course, besides many lesser streams, the conjoined rivers of Lowther and Eamont, enters Cumberland, which county it traverses in its course to the sea, at Rowcliff. The Lune, or Lun, hath its source in Ravenstonedale, and passing to the south, through a fine vale, to which it gives name, enters the county of Lancaster, formerly called Loncaster. The Ken, or Kent, has its origin in Kent-mere, and runs through a valley, called Kendale; passes the town of Kendal, and empties itself in the sea at Cartmel bay. The different rivulets from the eastern district empty themselves into the Eden, which, during its course through this county, receives its principal supplies. An irregular line, drawn east and west through the centre of Westmoreland, divides the direction of its several rivers: those on the north falling into the Eden, either before or at its entrance into Cumberland, except two or three small branches of the Tees, which rise on the eastern ridge of hills on the borders of the county of Durham. The rivers on the southern parts take a contrary direction, and enter the sea at different places.

The Lowther has its source in the Moors, above Wetsladdale, and passing Rosgill-hall, there unites with Swindale-beck, which rises near the slate-quarries; with the augmentation of a few other streams, it joins the Eamont.

The Eamont emerges from Ulls-water, and forms a boundary to parts of this county and Cumberland; and after being augmented by the waters of the Lowther river, which descends from the centre of the county, it joins the Eden as it enters Cumberland.

The Loyne, or Lune, has been described in a previous volume of this work, under LANCASTHIRE.

The Crake, a brook or rivulet, descending in several heads from a variety of dells on the side of Brackenthwaite-fell, passes through a very extensive peat-mofs to the Ken, just before its influx to the sea.

The Winter, or Winfler-beck, forms the boundary between the lower part of Westmoreland and Lancashire. It rises on the hills about two miles east from Windermere lake, and directs its course southwards, when it discharges itself in an estuary of the sea.

The Trout-beck is a brook issuing from the mountain High-freet, and unites itself with Windermere lake.

Rothay springs on the borders of Cumberland, among a number of high mountains; it runs several miles westward, and receives various streams in its progress to Grafmere.

Lakes.—Westmoreland is deservedly celebrated for its
fine

fine lakes. Among these, Windermere, or Winandermere, and Ulls-water, merit particular attention for size, and for the picturesque beauty of the scenery which furrounds them. They may be, and are by competent judges, regarded as unequalled in the kingdom.

Winandermere is a large lake of about ten miles and a half in length, by a breadth of from one to two miles; including an area, or sheet of water, of nearly 4534 acres. Its depth is in one place 23 fathoms, in a second 29, and in a third 31 fathoms. Four mountain streams, or rivers, supply this lake, and it is singular that its waters scarcely ever appear to be augmented or decreased. "Even in the most violent rains, when the country is drenched in water, when every rill is swelled into a river, and the mountains pour down floods through new channels, the lake maintains the same equal temper; and though it may spread a few yards over its lower shores, (which is the utmost it does,) yet its increase is seldom the object of observation; nor does the severity of the greatest drought make any considerable alteration in its bounds." In this lake are thirteen islands, the largest of which is now called Curwen's island. It contains about 27 acres of land, which are laid out in pleasure-gardens, walks, &c. around a very handsome mansion belonging to Mr. Curwen.

Ulls-water, part of which is known by the name of Ousemere, is a large and long lake, situated at the north-western extremity of the county, and partly in Cumberland. Next to Windermere, it is the largest sheet of water in this part of England. It covers an area of about nine miles in length from N.E. to S.W. by two in the broadest part, though the general width rarely exceeds a mile. Its sides are very irriuous, and from its shores the mountains rise in various bold, picturesque, and romantic forms; occasionally starting abruptly from the lake, and in other places ascending by gradual slopes. Towards the south-western end the mountains are on the grandest scale. On the northern and western sides the scenery is mostly rocky and woody. In some places its waters are from 29 to 35 fathoms deep. It abounds with trout, perch, skellies, and eels; also some char, and a large species of trout, some of which have been caught of ten pounds weight. In its highest part are a few small rocky islands.

Haws-water, in beauty and extent, ranks next. This lake is situated between Shap and Ulls-water, in a mountainous district; it is about three miles in length, and in breadth from a quarter to half a mile. The hills on the east side are high and rocky, and partially covered with wood. Those on the west are also high, but have a portion of low cultivated ground along the margin, which is divided into small farms. The narrowest part of this lake is said to be fifty fathoms deep.

Grafmere lake is a small but beautiful sheet of water, about a mile in length, and nearly half a mile broad, having its margin indented with numerous small bays with lofty and rocky eminences. Its situation is a few miles north of Ambleside. Near its centre is a small green island. The poet Gray describes this lake and its scenery in terms of high panegyric. "After passing the romantic mountain of Helm-Crag," he says, "opens one of the sweetest landscapes that art ever attempted to imitate. The bosom of the mountains here, spreading into a broad basin, discovers in the midst Grafmere-water; its margin is hollowed into small bays with bold eminences, some of rock, some of turf, that half conceal and vary the figure of the little lake they command. From the shore a low promontory pushes itself far into the water, and on it stands a white village, with the parish-church rising in the midst of it."

South of this, in the same vale, is Rydal-water, a small lake nearly a mile in length, and interspersed with wooded islands. Its water is shallow, and abounds with reeds.

On an elevated situation, nearly two miles west from Ambleside, is a small lake called Elter-water.

Broad-water is a small lake half a mile long, and a quarter of a mile broad, situated a few miles above Ulls-water.

Kentmere-tarn, a piece of water upwards of a mile long, and nearly half a mile broad, is situated in Kentmere-dale.

Skeggles-water, a very small lake, three miles north-east of Kentmere-tarn, is embosomed in the mountains of Longsleddale.

Sumbiggin-tarn, and Whin-fell-tarn, are small pieces of water; the former four or five miles east from Orton, well supplied with eels and a red trout, resembling char; and the latter about five miles north-east from Kendal.

The soil of Westmoreland is mostly dry and gravelly; but in the east and north, sand and hazel-mould are found. Clay prevails on a few farms towards the Eden and the eastern hills; and a moist soil appears in some northern districts. Peat-moss abounds on the tops of some high mountains, consisting of a dry soil upon a hard blue rock, provincially called *rag*. The soil that lies upon a stratum of lime-stone is esteemed the most profitable.

The Roads in Westmoreland, from the rocky nature of the country, are very firm and good. They are generally formed to wind gradually round the sides of the hills and along the vales, in such a manner, that the declivities of the former are mostly avoided. The principal roads leading through this county are those from Scotland and Cumberland to London, and the southern parts of England. These roads are united through Cumberland, but divide near Penrith, on the confines of Westmoreland: one turns eastwards, over Stainmoore, and through the centre of Yorkshire, to London, &c.; the other proceeds directly south, through Kendal, Lancaster, &c. to Manchester, Liverpool, Wales, the western counties of England, and also to London. A branch from this road goes through Kirkby-Lonsdale to the manufacturing towns in the West Riding of Yorkshire, and other southern districts.

Before the rebellion of 1715, the public roads of this county were almost impassable; but in that year the government planned several new roads: very little, however, was done to them before the more serious insurrection of 1745. This event impelled the government to direct some effectual repairs to be made. In 1774 an act of parliament was obtained to make a turnpike-road from Bowes to Brough. In this year, the first stage-coach from London to Glasgow was established to run this road. A mail began to travel through Kendal, &c. from London in 1786. Since which time the great roads have been kept in very good repair.

With the exception of some trifling veins of lead ore, few minerals have been found in the eastern part of this county. Coal is obtained only in the south-eastern extremity of Westmoreland, except an inferior quality called *crow-coal*, procured in the neighbourhood of Shap.

The county affords various sorts of valuable stone; particularly lime-stone, marble, gypsum, blue slate, and free-stone. There is great abundance of lime-stone, except among the western hills.

Marble of a beautiful kind was discovered a few years ago on the banks of the river Kent, near Kendal, and has been worked with success. The same vein has also been found on the opposite side of the river.

Blue slate of various sorts is dug from the rocky hills on the

the western side of the county; though great quantities are used in the country, yet much of the better sort is sent to London, Liverpool, Hull, and other large sea-ports. Beds of lime-stone are generally incumbent on beds of slate.

The buildings of Westmoreland are distinguished for their neat appearance. The houses are mostly built with lime-stone, or blue rag; thatched roofs are common, but slate is more generally used. In farm buildings, the barn is usually built upon the cow-house and stable, a method which requires the slope of a hill, as carts are carried along a level on one side into the barn. As very little corn or hay is stacked without, the barns are necessarily very spacious. There are many noblemen's and gentlemen's seats in this county; and also some pleasant villas which ornament the borders of the lakes.

The commerce of Westmoreland is not extensive. Its exports are chiefly a coarse woollen cloth, stockings, flates, tanned hides, gunpowder, hoops, charcoal, hams, wool, sheep, and cattle.

The manufactures of the county consist of silk and worsted waistcoat-pieces, knit worsted stockings, flannels, tanned leather, and gunpowder.

Formerly the whole county was governed by military tenure, *i. e.* by homage, fealty, and cornage, "which last drew after it wardship, marriage, and relief; and the service of this tenure was military service." Cornage appears to have been peculiar to the border-service against the Scots. Cornage, horn-geld, and nout-geld, were probably synonymous, and implied annual payments of horned cattle, to provision the garrisons. The lord's rent was called white-rent, probably from its being paid in silver. Scutage, or service of the shield, was another compensation in money, instead of personal service against the Scots.

Some veins of *copper* ore have been found and worked in different parts of the county; but the product has not been found sufficient to defray the expence of workmanship. Before the year 1704, great quantities of *lead* were found near Hartley. Some mines at Dunfell have proved very productive of this metal for many years, but latterly there has not been much ore found. At Dufton are some rich and productive lead mines, belonging to the earl of Thanet. There are some considerable mines at Greenside, near Paterdale, and at several other places in the county. This metal is obtained in various quantities.

Crofs-fell, the highest of the chain of mountains which extend along the eastern frontiers of the county of Westmoreland and Cumberland, is said by Robinson, in his Natural History of the County, to have been formerly called Fiend's-fell, from evil spirits which are said in former times to have haunted its summit, and continued their haunts and nocturnal vagaries upon it until St. Austin, as is reported, erected a cross, and built an altar upon it, whereon he offered the Holy Eucharist, by which he counter-charmed those hellish fiends, and disturbed their haunts. Since that time it has been named Crofs-fell; and unto this time there is a heap of stones on the summit, which bears the name of Crofs-fell.

Upon this and the adjoining mountains occurs the phenomenon, called the Helm-wind; which, in spite of St. Austin's charms, continues its vagaries on its ancient haunts. It is peculiar to this district, and the confines of Lancashire and Yorkshire, about Ingleborrow, Pendle, and Penigent. It also occurs on Wildboar-fell, in Ravenstonedale; and is most prevalent in the months from October to April. The appearances attending it are a whitish cloud hanging half way down the mountains, but keeping an exact parallelism with every plane, depression, and elevation of their tops,

which it covers as with a helmet. Above this appears the blue sky, and then a white cloud, called the helm-bar, from an idea that it represses the fury of the storm: it continues in a tremulous agitated motion till it disperses; and then the hurricane issues forth, roaring along the sides of the hills, and frequently extending two or three miles from their sides. The following are the heights of the principal mountains, as ascertained by Mr. Dalton. Helvellyn is 1070 yards high. A deep drift of snow was seen on this mountain on the 12th of July, 1812. Bowfell and Rydal-head are each 1030 yards in height. The High-freet is 912 yards high. On its summit are annual horse-races, and other sports, on the 10th of July, to which every one brings the sheep that have strayed into their heathing-ground, for their owners to challenge.

It appears that different grammar-schools were established in this county previous to the dissolution. Edward VI. was patron of the school at Kendal; and queen Elizabeth founded schools at Appleby, Kirkby Stephen, and Kirkby Loufsdale. From these seminaries many learned men have been distributed over England, some of whom have obtained eminence in the literary world. They have also contributed towards the establishment of other public schools in the county. Seminaries are, therefore, established in nearly every village in Westmoreland.—The History and Antiquities of the Counties of Westmoreland and Cumberland, by Joseph Nicholson, esq. and Richard Burn, LL.D. 2 vols. 4to. 1778. An Essay towards a Natural History of Westmoreland and Cumberland, by the Rev. Thomas Robinson, 8vo. 1709. General View of the Agriculture of the County, by Andrew Pringle, 4to. 1794. Observations relative chiefly to Picturesque Beauty of the Mountains and Lakes of Westmoreland and Cumberland, by the Rev. William Gilpin, 2 vols. 8vo. 1788. A Survey of the Lakes, by James Clarke, folio.

WESTMORELAND, a post-township of New York, in Oneida county; 10 miles W. of Utica, and 107 miles from Albany. Its waters are small; its surface very level, but the soil is very rich and fertile. It has a church for Congregationalists, and a competent number of common schools. In 1810, the population was 1135, and the senatorial electors were 141.—Also, a county of Pennsylvania, containing 26,392 inhabitants, of whom 20 are slaves.—Also, a county of Virginia, containing 8102 inhabitants, of whom 4080 are slaves.—Also, a township of New Hampshire, in the county of Cheshire, on the E. bank of the Connecticut, containing 1937 inhabitants; 5 miles N. of Chesterfield.

WEST NANTMILL, a township of Pennsylvania, in the county of Chester, with 1188 inhabitants.

WEST NORTHERN LIBERTIES, a town of Pennsylvania, in the county of Philadelphia, containing 9795 inhabitants.—Also, a township of the same, containing 168 inhabitants.

WEST NOTTINGHAM, a township of Pennsylvania, in the county of Chester, with 642 inhabitants.

WESTOE, a township of Durham, with 2900 inhabitants; 2 miles S. of Shields.

WESTON, a township of Connecticut, in the county of Fairfield, with 2618 inhabitants; S. of Fairfield.—Also, a town of Vermont, in the county of Windsor, containing 629 inhabitants; 30 miles N.N.E. of Bennington.—Also, a town of the state of Massachusetts, in the county of Middlesex, containing 1008 inhabitants; 12 miles W. of Boston.

WEST PENNSBOROUGH, a township of Pennsylvania, in the county of Cumberland, with 1264 inhabitants.

WESTPHALIA, a circle of Germany, bounded on the

the N. by the Dutch states, on the W. by the Netherlands, and elsewhere by the circles of the Rhine, Upper and Lower. The ancient Saxons were divided into Westphalians, Angrians, and Eastphalians. The people inhabiting between the Wefer and the Rhine, were called *Westphalians*, and the tract of country inhabited by them, has from thence been called *Westphalia*. The duchy of that name, in the electoral circle of the Rhine, constituted a part of this country; but the circle of Westphalia comprised also under it other countries, which never belonged to the above-mentioned Westphalia. And thus we must carefully distinguish from each other the three denominations, which are, the circle of Westphalia, Westphalia itself, and the duchy of that name. Formerly, not only certain states were reckoned in this circle, which at present no longer belong to it, as Utrecht, Guelderland, Zutphen, the bishopric and city of Cambray; but in other respects, also, the ancient and the modern lists of the countries of the Westphalian circle differ greatly from each. The following appeared to be states of the Westphalian circle before the peace of Luneville, *viz.* the bishoprics of Paderborn, Munster, Liege, and Osnabruck; the duchy of Verden; the principality of Minden; the abbeys of Corvey, Stablo, Werden, Cornelius Munster, Essen, Thorn, and Hervorden; the duchy of Cleves, with the county of Mark; the duchies of Juliers and Berg, Nassau Siegen, and Nassau Dillenburg; the principalities of East Friesland and Meurs; the counties of Sayn, Wied-Runkel, Schauenburg, Oldenburg, Delmenhorst, Lippe, Bentheim, Tecklenburg, Hoya, Virnenburg, Diepholz, Spiegelberg, Rietberg, Pyrmont, Gronsfeld, Reckheim; the signories of Anhalt and Winneburg; the county of Holzappel; the signories of Witten, Blankenheim, Geroldstein, Gehmen, Gimborn and Neustadt, Wickerad, Mylendonk, and Reichenstein; the county of Kerpen and Lommerfum; the signiory of Schleiden, and the county of Hallermund, to which in the matricula are reckoned moreover to belong the signiories of Dyck, Severn, Kniphausen, Keyl, Mechernick, Eys, Schlenacken, Wylre, Richold, Dreyz, and Schonau, together with the cities of Cologne, Aix-la-Chapelle, and Dortmund. The summoning princes, and directors of the circle, were the bishop of Munster, and with him alternately the electors of Brandenburg and Palatine, as dukes of Cleves and Juliers, both of whom in this directory enjoyed together but one voice. The diets of the circle were usually appointed at Cologne. The archives belonging to it were kept at Dusseldorf. The contribution of this circle in men and money, to the aids of the empire, was made equal to the contributions of Upper and Lower Saxony, Burgundy, and Swabia, and rated at somewhat more than the ninth, but less than the tenth part of the whole sum granted by the empire. With respect to religion, this circle was one of the mixed. Indeed the Catholic states used to nominate two, and the Protestant also the like number of assessors, to assist at the Imperial and chamber court of the empire. By the peace of Luneville, all that part of the circle which lay on the left bank of the Rhine, was ceded to France.

WESTPHALIA, (*Duchy of*) a country of Germany, bounded on the N. by the bishopric of Munster and county of Lippe, on the E. by Paderborn, Waldeck, and Hesse; on the S. by Witgenstein, Nassau, and Berg; and on the W. by Berg and Mark; about forty miles in extent from N. to S. and thirty-two from E. to W. Agreeably to its natural situation, this county is divided into three parts. The first of these, called the *Hellwege*, is low, and produces plenty of corn and other necessaries, with a sufficient breed of cattle and salt-springs. The second is the *Haarfrank*,

which stands somewhat higher, between *Hellwege* and the *Sunderland*, and has indeed a good, but not so fruitful a soil as the *Hellwege*. The third is the *Sunderland*, commonly called the *Surland*, or *Saurland*, which consists of hills and vales. This tract indeed is neither of great, nor even a sufficient fertility in corn; but, on the other hand, it has fine woods and meadows, together with a good breed of cattle, game, and fish, in particular trout, as also plenty of iron ore, calamy, lead, copper, silver, and gold. The principal rivers are, the Ruhr, the Lenne, the Dimel, and Lippe. The duchy of Westphalia contains in it thirty-five towns. Henry, duke of Bavaria and Saxony, being put under the ban by the emperor Frederic I. in the year 1180, the latter made a donation of the duchy of Westphalia, as also a part of the duchy of Engern, which belonged to the former, to the archbishopric of Cologne, and invested therewith the archbishop Philip; concerning which donation, in the same year, a record, or instrument, was executed at Gelnhausen, and the said donation confirmed afterwards in the year 1200, by the emperor Otho IV., as also in the year 1204, by the emperor Philip. In the year 1368, Godfrey, the last duke of Arensburg, and his consort Anne, ceded the county of Arensburg to the archbishopric of Cologne; and, in the year 1371, the emperor Charles IV. invested the archbishop Frederic therewith. The county was afterwards added to the share of the duchy of Engern. The archbishops and electors of Cologne governed this duchy, till the year 1442, by marshals, but afterward under the direction of an electoral bailiff. Brilon is the capital. In 1802, the duchy of Westphalia was given to the prince of Hesse Darmstadt.

WESTPHALIA, a kingdom formed of several principalities, taken from the king of Prussia, after the battle of Friedland, and acceded to at the peace of Tilsit. Westphalia is divided into eight departments. 1. That of the Elbe; consisting of the greater part of the duchy of Magdeburg, with the Old Mark of Brandenburg. Its population is 253,000 souls: the chief place Magdeburg. 2. That of Fulda: the chief place Cassel. It is composed of a part of Lower Hesse, of the countries of Paderborn, Corvey, Minden, &c. Its population 239,502 inhabitants. 3. That of the Harz: chief place Heiligenstadt. It consists of Eichsfeld, of the cities of Mulhausen and Nordhausen, of the principalities of Hohenstein, Grubenhagen, Blankenburg, &c. Its population is 210,989 souls. 4. That of the Leine: chief place Gottingen. It is composed of a part of the principality of Grubenhagen, and of the countries of Hildesheim, Brunswick, and Hesse. Its population is 145,537 souls. 5. That of the Ocher: chief place Brunsvick. It is composed of the greater part of the duchy of Wolfenbittel, and the bishopric of Hildesheim. Its population is 267,878 souls. 6. That of Saal: chief place Halberstadt. It is composed of the principalities of Halberstadt, Wernigerode, Quedlinburg, &c. The population is 206,222 souls. 7. That of the Werra: the chief place Marburg. It consists of Upper Hesse, the Hersfeld, &c. The population is 254,000 souls. 8. That of the Wefer: the chief place Osnabruck. It consists of the bishopric of Osnabruck, a part of Schaumburg; and its population is 334,000 souls.

WESTPHALIA-Ham. See **HAM**.

WESTPOND PLANTATION, in *Geography*, a town of the district of Maine, in the county of Kennebeck, containing 481 inhabitants.

WESTPORT, a township of Massachusetts, in the county of Bristol, incorporated in 1787, with 2585 inhabitants; 60 miles S. of Boston.

WESTPORT, a sea-port and post-town of Ireland, in the county of Mayo, situated on a beautiful bay, wooded to the water's edge, in the S.E. angle of that large haven called Clew bay, founded by the late marquis of Sligo, whose residence was within half a mile of it. Westport is a neat regular well-built town, 123 miles W.N.W. from Dublin, and $8\frac{1}{2}$ S.W. from Castlebar. The following account, extracted from a late report to the Linen Board by Peter Bernard, esq. shews what judicious indulgence and liberal protection on the part of a landlord, assisted by the exertions of an industrious individual, may do. Were the example universally imitated, many squalid and decayed villages would quickly assume a more comfortable and exhilarating aspect. "The establishment and success of the linen manufacture in Westport, is due to the persevering attention of the marquis of Sligo and Robert Patten, esq. The latter, most fortunately for the neighbourhood, settled here in the year 1787; at that period Westport was a very inconsiderable town, containing but few houses, and its general market attended only by two or three hundred persons; now it is a beautiful well-built town, with 3700 industrious inhabitants, and many gentlemen of the highest respectability residing in it. Its market at present (1817) is attended by from 4000 to 5000 persons, whose manners, appearance, and dress, bespeak most strongly the happy effects of a well-regulated system of industry." "The first linen-market was held in 1790. For the first five years it produced only eight webs *per* week, and Mr. Patten was the only buyer; but he, by giving fair and liberal encouragement to the weavers, gradually but firmly advanced the trade, which now stands on a foundation not likely to be shaken. An accession of settlers from Ulster in the years 1797, 98, and 99, who brought their looms, some capital, and their accustomed habits of industry, completed what Mr. Patten had so fortunately begun." At present the market is held every Thursday in a spacious linen-hall built by the marquis of Sligo, where the goods are measured by a machine. The linens are all seven-eighths of three different qualities, and are all brought to market in a brown state. There are sold weekly about 200 webs, the value of which is estimated at above 20,000*l.* *per annum.* There are about 150 weavers and about 20 buyers, two of whom have bleach-greens at Westport. Mr. Patten has also successfully introduced at Westport the provision and corn-trade, and also the oil business, which is carried on to a considerable extent, and gives employment in the season to a great number of fishermen and boats. In March and April a number of fish appear off the coast, which, from their appearing only on a sunny day, the inhabitants call *sun-fish*, though they differ from the fish usually so called. The fishermen strike these with harpoons, then cut out the liver, and abandon the rest of the fish, the liver being sufficient to load one boat of four tons burden. A large fish yields eight barrels of oil and two of sediment. This trade amounts to some thousands annually, and Mr. Patten's house has often bought in one year near 3000*l.* worth. The oil is esteemed as good as spermaceti oil, and is particularly well-suited for lamps, as it has no offensive smell. The price of the present day is five shillings *per* gallon; the dregs are used by tanners. Bernard's Report to the Linen Board in 1817.

WESTRAY, one of the Orkney islands, terminating the cluster on the N.W. quarter, is situated 20 miles N. from Kirkwall, and 347 miles in the same bearing from Edinburgh. Its shape bears some resemblance to that of a cross; of which the longer part extends about eight miles, the arms or transverse part not more than five, and comprehends in the whole about fourteen square miles. The island

comprises two parishes, St. Mary's and Cross Kirk; and in the population return of the year 1811 was stated to contain 248 houses, and 1396 inhabitants. The only manufacture is that of kelp, of which are produced on an average 300 tons annually. Much corn is raised, but of an indifferent quality; the grass is excellent for the dairy, and for the pasturage of black cattle; and the boisterous seas which surround the island afford great plenty of fish, of a very superior kind. On the east and south are two bays; but the only harbour that can be depended on is on the north-east, and this is fit for small vessels only: formerly it received ships of much greater burthen; but from the blowing of the sand the water has become so shallow, they are now compelled to anchor in a more open road. In two extensive plains near the sea-side, one on the south, the other on the north part of the island, a multitude of graves have been discovered, all formed in nearly the same manner; and, though tradition is silent, they were probably formed after a sanguinary conflict at some remote period: some of these graves, on the north side, have been opened, and were found to contain skeletons in a reclining posture, with weapons, domestic utensils, and several other articles, the use of which could not be ascertained.—*Beauties of Scotland*, vol. v. Orkneys, 1808. *Carlisle's Topographical Dictionary of Scotland*, 1813.

WESTRINGIA, in *Botany*, was so named by the author of the present article, in honour of Dr. John Peter Westring, physician to the king of Sweden, member of the Royal Society of Stockholm, and author of several learned papers on the *Lichen* tribe, published in the *Transactions* of that body. He has also published seven numbers in 8vo. on the dyeing properties of many Swedish lichens, comprehending a full history of the modes of applying them to use, and accompanied with most elaborate and complete coloured figures, drawn by the celebrated professor Acharius himself.—*Sm.* in *Stockh. Transf.* for 1797, 171. *Tracts* relating to *Nat. Hist.* 277. *Mart. Mill. Dict.* v. 4. *Brown Prodr.* Nov. *Holl.* v. 1. 501. *Ait. Hort. Kew.* v. 3. 372.—*Class* and order, *Didymia Gymnospermia*. *Nat. Ord.* *Verticillate*, *Linn. Labiate*, *Juss. Brown.*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, somewhat bell-shaped, with five sides and five prominent angles, but no furrows, divided about half way down into five equal, erect, lanceolate, beardless segments, permanent. *Cor.* of one petal, ringent, twice as long as the calyx: tube the length of the calyx, hairy in the throat: limb two-lipped; the upper lip flat, erect, divided, rather the longest; lower in three oblong, equal, spreading, entire segments. *Stam.* Filaments four, shorter than the limb, divaricated, the two upper ones longest; anthers of the two upper stamens roundish, halved, those of the two lower deeply divided, imperfect. *Pist.* Germen in the bottom of the calyx, four-lobed; style thread-shaped, the length of the longer stamens; stigma small, cloven, acute. *Peric.* none, except the hardened calyx. *Seeds* four, obovate, naked.

Ess. Ch. Calyx five-cleft half way down, five-sided. Upper lip of the corolla flat, cloven; lower in three deep equal segments. Stamens distant; the two upper with halved anthers; two lower with divided abortive ones.

A genus of New Holland shrubs, chiefly from the colder parts of that country, having the appearance of our rosemary, destitute of glands, but mostly downy. *Leaves* whorled, entire. *Flowers* axillary, solitary, on short stalks, with a pair of *bractes* close to the calyx. *Corolla* white, sometimes dotted with purple or violet. One species only was, for a long time, known to us, but Mr. Brown has

ascertained seven more, one of which, it seems, was brought home by the famous old navigator Dampier, and is preserved in the Sherardian herbarium at Oxford, if we remember right. They all very much resemble each other in habit, and prove the genus to be perfectly natural, though it has been confounded with *Cunila* by some very eminent botanists.

1. *W. rosmariniformis*. Rosemary-leaved Westringia. Sm. in Stockh. Transf. for 1797, 175. t. 8. f. 2. Tracts 282. t. 3. Brown n. 1. Ait. n. 1. Donn. Cant. ed. 5. 141. (*W. rosmarinacea*; Andr. Repof. t. 214. *Cunila fruticosa*; Willd. Sp. Pl. v. 1. 122.)—Leaves four in a whorl, lanceolate, revolute; shining and nearly smooth above; silky beneath. Calyx silky; its teeth longer than the tube.—Native of New South Wales, near Port Jackson, from whence specimens and seeds were sent by Dr. John White, in 1791. The stem is shrubby, several feet high, very much branched; branches either opposite, or four together, square, silky with white close hairs, densely leafy. Leaves spreading, an inch or somewhat less in length, acute, single-ribbed, entire; dark green, and polished above; white with silky hairs beneath. Footstalks broad and very short, silky, without stipulas. Flowers about the upper part of the branches, shorter than the leaves; their corolla spreading nearly an inch, white, dotted about the mouth with violet spots. Anthers violet. The calyx is silky on the outside of the tube, its segments naked with revolute margins; they appear to us variable in length. The plant is slightly bitter, not aromatic; nor have the flowers any scent.

2. *W. Dampieri*. Dampier's Westringia. Br. n. 2. Ait. n. 2.—“Leaves four in a whorl, linear, strongly revolute; nearly smooth above; hoary and opaque beneath. Calyx hoary and opaque; its teeth half the length of the tube.”—Gathered by Mr. Brown on the southern coast of New Holland. Sent to Kew in 1803, by Mr. Peter Good. It flowers in the greenhouse, from May to July. Aiton.

3. *W. rigida*. Rigid Westringia. Br. n. 3.—“Leaves three in a whorl, linear-lanceolate, divaricated, sharp-pointed, revolute; smoothish above; hoary beneath. Calyx hoary; its teeth half the length of the tube.”—Discovered by Mr. Brown, in the south part of New Holland.

4. *W. cinerea*. Grey Westringia. Br. n. 4.—“Leaves three in a whorl, linear, spreading, pointed, revolute, hoary on both sides. Calyx hoary; its teeth scarcely a quarter the length of the tube.”—This was found by Mr. Brown, in the same country as the last species.

5. *W. angustifolia*. Narrow-leaved Westringia. Br. n. 5.—“Leaves three in a whorl, linear, spreading, revolute; roughish on the upper side; hoary beneath. Calyx hoary; its teeth half the length of the tube.”—Found by Mr. Brown, in the island of Van Diemen.

6. *W. longifolia*. Long-leaved Westringia. Br. n. 6.—Leaves three in a whorl, linear, revolute; rough with minute points on the upper side; slightly hairy beneath. Calyx somewhat hairy; its teeth equal to the tube.—Gathered near Port Jackson by Mr. Brown. We have specimens, gathered in that country by Dr. White, which answer to the specific character, except that the back of their leaves, as well as the calyx, are rather hoary than, as Mr. Brown says, green, and the leaves are four, or even five, in a whorl. The corolla is externally downy; but this last character is, perhaps, not peculiar to the present species.

7. *W. glabra*. Smooth Westringia. Br. n. 7.—“Leaves three in a whorl, linear-lanceolate, flat, smooth on both sides, as well as the calyx.”—Gathered by Mr. Brown, in the tropical part of New Holland.

8. *W. rubifolia*. Madder-leaved Westringia. Br. n. 8.—“Leaves four in a whorl, elliptic-lanceolate, nearly flat, very smooth and shining. Calyx nearly smooth.”—Found in the island of Van Diemen, by Mr. Brown.

The two last species seem to differ remarkably from all the foregoing, in the flatness and smoothness of their leaves.

WESTRIZ, in *Geography*, a river of the duchy of Stiria, which runs into the Luffnitz, near Furtzenfeld.

WESTS, a town of Virginia; 4 miles S.W. of Leesburg.

WEST SALEM, a township of Pennsylvania, in Mercer county, with 660 inhabitants.

WEST SOUTHWARK, a town of Pennsylvania, in the county of Philadelphia, containing 6443 inhabitants.

WEST SPRINGFIELD, a town of Massachusetts, in the county of Hampshire, containing 3109 inhabitants.

WEST STOCKBRIDGE, a town of Massachusetts, in the county of Berkshire, containing 1049 inhabitants.

WEST WHITELAND, a township of Pennsylvania, with 636 inhabitants.

WEST WINDSOR, a town of New Jersey, in the county of Middlesex, containing 1714 inhabitants.

WET AIR. See MOISTURE.

WET Couch, a term used by the maltsters for one of the principal articles of malt-making.

In the making of malt, the usual way is to soak the grain in water two or three days, till it becomes plump and swelled, and the water is brown; the water is then drained away, and the barley is removed to a floor, where it is thrown into a wet couch, that is, an even heap of about two feet thick.

In this heap the barley spontaneously heats, and begins to grow, shooting out first the radicle, and, if suffered to continue growing, soon after the blade; but at the eruption of the radicle, the process is to be stopped short, by spreading the wet couch thin over the floor, and turning it once every four or five hours for two days, laying it thicker each time; after this it is thrown into a large heap, and there suffered to grow hot of itself, and afterwards spread abroad again and cooled, and then thrown upon the kiln to be dried crisp, without scorching. Shaw's Lectures, p. 186.

WET Dock. See DOCK.

WET-Glover, a dresser of the skins of sheep, lambs, goats, &c. which are slender, thin, and gentle.

WETA, or WINDAU, in *Geography*, a river of the duchy of Courland, which runs into the Baltic, a little below Windau.

WETERFELD, a town of Bavaria, on the Regen; 21 miles N.E. of Ratibon.

WETHER-GETTER, among *Sheep-Farmers*. See RAM.

WETHER-Sheep, in *Rural Economy*, a term applied by stock-farmers to a castrated male sheep of more than one year old; but before that time it is called a wedder-lamb. The wethers of the improved breeds of sheep, especially those of the new Leicester sort, are much more early than the old kinds. See SHEEP.

WETHERBY, in *Geography*, a market-town in the upper division of the wapentake of Claro, West Riding of the county of York, England, is situated on the river Wharfe, 7 miles N.W. from Tadcaster, about the same distance S.E. from Knaresborough, and 194 miles N.N.W. from London. The course of the river forms an angle, whose sides are each about one mile in length; at the point of this angle the town is seated. It affords nothing worthy of notice, but a handsome bridge crossing the Wharfe. Above this bridge the river forms a beautiful cascade, by falling

falling in a sheet of water over a high dam erected for the convenience of the mills. Over this cascade, the salmon, in their way up the river from the sea, are seen to leap with wonderful dexterity. Wetherby has a weekly market on Thursdays, and three annual fairs. In the population return of the year 1811, the town is stated to contain 1140 inhabitants, occupying 243 houses. In the time of William the Conqueror, this manor was possessed by two Norman lords, William de Percy and Erneis de Burun. It was afterwards given to the knights templars; and, together with all their estates in England, was forfeited on the abolition of their order, in the year 1312. In the civil war of Charles I. this town was garrisoned by sir Thomas Fairfax, who, in 1642, repulsed sir Thomas Glenham, in two different attacks. A little below the town is St. Helen's Ford, where the Roman military-way crossed the Wharfe. Within a mile of the town is Wetherby Grange, the seat of Richard Thompson, esq. In the park is an heronry, a thing rather uncommon in this part of the country. The herons build their nests in the tops of the highest trees; but seldom take the trouble, when they can get them ready made by the rooks, whom they expel, and enlarge and line the nests, driving away the original possessors, should they happen to renew their fruitless claims.

About two miles to the west of Wetherby, is Stockeld park, the seat of William Middleton, esq. His ancestors descended from Hypolitus de Brame, lord of Middleton, who lived in the reign of Henry II. Not far from the house, and near the high road, is a rock of a very singular shape, 65 feet in circumference, and 30 feet high, standing on the margin of a lake.—Hargrove's History of Knaresborough, 1809. Beauties of England and Wales, vol. xvi. Yorkshire. By J. Bigland, 1812.

WETHERSFIELD, a town of Connecticut, in the county of Hartford, containing 3961 inhabitants.

WETMORE'S ISLAND, a small island on the coast of Massachusetts, at the mouth of the river Penobscot.

WETSTEIN, JOHN JAMES, in *Biography*, was born at Basle in 1693, and made such proficiency in his early studies, that he was fit to be admitted into the university at the age of eleven years. In his 20th year he was ordained minister, on which occasion he maintained a disputation on the various readings of the New Testament, in which he defended the authenticity and integrity of the text. To this course of study he was sedulously devoted, and in order to explain the words and phrases of the New Testament, he carefully read the Greek authors, both sacred and profane; and he also consulted the Rabbinical writings, for the purpose of acquainting himself with the opinions and customs of the Jews. Richly furnished with this kind of knowledge, he set out, in 1714, on a literary tour to Zurich, Berne, and Geneva. From the latter place he proceeded through Lyons to Paris, where he became acquainted with Montfaucon, Courayer, and other eminent men; and he also visited England, where he was particularly noticed by the celebrated Bentley, and diligently searched for MSS. of the New Testament. During his stay in this country, he was made chaplain to a regiment of Swift's troops, and having obtained leave of absence, visited Paris, in order to collate a particular MS., and, after three months, joined the regiment at Bois-le-duc. Having afterwards visited Holland and Germany, he returned to Basle in 1717, and became deacon to the church of St. Leonard, which office he held with distinguished approbation for nine years. In pursuance of his main object, he corresponded with Bentley on the subject of various readings; but he was interrupted in his plan by a violent dispute with a divine of Basle, who had

been his intimate friend, occasioned by his publication of a specimen of his various readings in 1718. In the progress of this dispute, the clergy took a part, and presented a petition to the council, requesting that Wetstein's edition of the New Testament might be prohibited; alleging, amongst other objections, that it favoured of Socinianism. His Prolegomena, however, were printed in 1730, and a new accusation was preferred to the council against the author. This kind of clamour proving ineffectual, his enemies engaged some of his pupils to appear as witnesses against him; and they produced extracts of his lectures from the MS. copies of these pupils to support their accusation. The result of these dishonourable proceedings was a suspension of his functions in 1729, and this was soon followed by his total deposition. This conduct of the clergy was aggravated by a variety of misrepresentations; the ministers of Mulhausen, Neufchatel, Vallangen, and Geneva, expressed their disapprobation of these measures; and forty heads of families in the parish of St. Leonard presented a petition for obtaining Wetstein's re-establishment. But as this interposition on his behalf was unsuccessful, he left his native country, and removed to Amsterdam, where the Remonstrants elected him professor of philosophy in the room of Le Clerc, requiring, at the same time, that he should justify himself, either by a public apology, or before the council at Basle. Adopting the latter method, he returned to Switzerland, and in the presence of thirteen commissioners, chosen from the council and body of the professors, he shewed that the extracts furnished by his pupils were not worthy of credit; that the witnesses had sworn nothing that could prove the accusation alleged against him; and that the acts of the divines contradicted each other. The council, in March 1732, annulled the decree of condemnation, and restored him to the full exercise of his functions. The Remonstrants at Amsterdam were satisfied, and in 1733 he took possession of his office, the duties of which he faithfully discharged till his death. His character being re-established at Basle, he was elected in 1744 professor of the Greek language; but the Remonstrants, in order to retain him, nominated him professor of ecclesiastical history, and made an addition to his salary. Amidst the labours of the offices, which he sustained with great honour to himself and benefit to his pupils, he proceeded in collecting and arranging his various readings of the New Testament; grudging no expence, and availing himself of every opportunity that occurred in collating various MSS. Encouraged by a great number of learned men in England, Holland, and Germany, he at length published his first volume in 1751, and the second in the following year; and in order to preclude every objection, he printed the text from that commonly received, and the various readings at the bottom. To the whole he subjoined a commentary, comprehending all the remarks with which he had been furnished by the Hebrew, Greek, and Roman writers whom he had consulted. His attachment to received principles is evinced by his mode of explaining several passages, and particularly those which related to the divinity of Jesus Christ. To his New Testament he added two epistles of St. Clement, now first published, with a Latin version, and a dissertation on their authenticity. His literary reputation being now established, he was made a foreign associate of the Academy of Sciences at Berlin, in 1752; and in the following year elected a fellow of the Royal Society in London. Although Wetstein's constitution was vigorous, his incessant labour accelerated the infirmities of age; and he was seized with a numbness and coldness in his right leg, which threatened a gangrene, and all attempts to check the progress of this malady were ineffectual; so that it terminated his valuable life

in March 1754, in the 61st year of his age. He beheld the approaches of death with tranquillity and resignation. Wetstein was social, and fond of innocent amusements, though studious. He was an excellent Greek scholar, possessed a retentive memory, and spoke several modern languages. He was affable even to strangers, and kind and condescending to his pupils. His benevolence comprehended all of every nation and communion, and he was prompt in communicating assistance and advice to all who applied to him. His character has been amply vindicated from invidious and degrading charges by Kriehout, in his "Memoria Wetsteiniana Vindicata," 4to. Formey's Elog. Gen. Biog.

WETTELSHEIM, in *Geography*, a town of Germany, in the principality of Anspach; 4 miles N.W. of Treuchtlingen.

WETTENHAUSEN, a princely abbey, founded in the tenth century; 20 miles W. of Augsburg.

WETTER, a town of Germany, in the county of Mark; 6 miles S.W. of Schwiert.—Also, a town of Germany, in the principality of Hesse; 6 miles N.W. of Marburg. N. lat. $50^{\circ} 54'$. E. long. $8^{\circ} 45'$.—Also, a river of Germany, which rises in the county of Solms, and runs into the Nidda, at Assenheim.

WETTER *Island*, an island in the East Indian sea, about 90 miles in circumference, of an irregular form. S. lat. $7^{\circ} 24'$. E. long. $126^{\circ} 40'$.

WETTER *Lake*, a lake of Sweden, in East Gothland, sixty-five miles long, and from ten to sixteen wide. This lake has but one outlet by the river Motala, though above forty little streams discharge themselves into it. This lake lies much higher than either the Baltic or the North sea, and is deep and clear, but very boisterous in winter. It is supposed certainly to prognosticate the approach of stormy weather. As this lake, like all inland pieces of water, surrounded with hills or mountains, is subject to sudden storms in the stillest weather, superstition and credulity co-operating, as in other cases, have been busy in explaining and admitting causes for this phenomenon; and accordingly it has been reported and credited, that these sudden storms are occasioned by a subterraneous communication with the lake of Constance in Switzerland. It is said, that by a regular series of correspondence and observation it was found, that when the waters of one lake arose, those of the other fell in the same proportion; and frequently the waters of the Wetter were violently agitated without the least wind, or any apparent cause, until information arrived that at the same time the lake of Constance had been disturbed by a tempest. The whole is supposed to be a fable grounded on some antiquated tradition. See WADSTENA.

WETTERAU, or WETTERAVIA, a country of Germany, situated between the county of Hesse and the river Maine, which takes its name from the river Wetter. It contains the counties of Siegen, Schaumburg, Dillenburg, Dietz, Hadamar, Weilburg, Idstein, Hanau, Solms, Wetterburg, Isenburg, Sayn, Witgenstein, Hohenstein, Cronberg, and Waldeck, the lordships of Weid, and the imperial towns of Wetzlar, Friedberg, and Gelnhausen. The northern part is called Wetterwald.

WETTERINGEN, a town of Germany, in the bishopric of Munster; 7 miles S.W. of Rheine.

WETTING, a town of Westphalia, in the duchy of Magdeburg, on the Saal, the principal place of a bailiwick, which was formerly a county, in the year 1283 granted to the cathedral of Magdeburg. In the neighbourhood are some coal-mines; 34 miles S. of Magdeburg. N. lat. $51^{\circ} 37'$. E. long. $12^{\circ} 3'$.

WETTINGEN, a town of Switzerland, and principal

place of a bailiwick, in the county of Baden, on the Limmat, with a celebrated wooden bridge of one arch over the river, executed by the same person who built the bridge over the Rhine, at Schaffhausen; 1 mile S. of Baden.

WETZ, a river of Germany, which runs into the Lahn, near Wetzlar.—Also, a town of Germany, in the principality of Solms Braunsfels; 5 miles S. of Wetzlar.

WETZLAR, an imperial town of Germany, in the circle of the Upper Rhine, situated on the Lahn. The Roman Catholics, the Lutherans, and the Calvinists, have each a church; 45 miles E. of Coblenz. N. lat. $50^{\circ} 34'$. E. long. $8^{\circ} 33'$.

WEVELSBURG, a town and citadel of Westphalia, in the bishopric of Paderborn; 8 miles S. of Paderborn.

WEVER, a river of England, in the county of Chester, which runs into the Dee, 7 miles N. of Chester.—Also, a river of England, in the county of Devon, which runs into the Culm, near Bradninch.

WEVERHAM, a township of England, in Cheshire; 3 miles W. of Northwich.

WEVERY, a river of Wales, which runs into the Wye, near Builth.

WEWER, or WEVER, a town of Westphalia, in the bishopric of Paderborn; 22 miles S.S.W. of Paderborn.

WEWURTZE, a river of Lithuania, which runs into the Minnic, 3 miles S. of Proeculis.

WEXEL, a mountain of Stiria; 4 miles N.W. of Fridberg.

WEXFORD, a county of Ireland, in the south-east part of it, which has St. George's Channel on the E. and S., the counties of Waterford, Kilkenny, and Carlow, on the W., and that of Wicklow on the N. It extends from N. to S. 44 Irish miles, and from E. to W. 25; being 56 English miles in length, by 32 in breadth. It contains 342,900 acres, or 535 square miles Irish, equal to 550,888 acres, or 695 square miles in English measure. The number of parishes 142, having 41 churches, all of which, except two parishes with one church, are in the diocese of Farns. The population was estimated by Dr. Beaufort at about 115,000. Wexford forms almost a peninsula, being separated from Waterford and Kilkenny by the haven of Waterford, and the deep and navigable river Barrow, and from the counties of Carlow and Wicklow by formidable ranges of mountains, which admit of few passes. Being situated next to the principality of Wales, and nearly opposite to the mouth of the British Channel, it presented great advantages to the English invaders of Ireland in the reign of Henry II.; who, after their first victories over the natives, selected this county, from its natural strength, for the residence of the first colonists. The inhabitants of the baronies of Bargie and Forth are supposed to retain traces of their descent from these settlers. (See BARGIE.) Wexford cannot be called hilly or mountainous, except on the frontiers of Carlow and Wicklow. Yet it contains a great deal of coarse cold land, and stiff clay soil, which the want of lime-stone renders it difficult and expensive to improve. The baronies of Bargie and Forth, being of a lighter soil, are well tilled, and produce large quantities of barley. The river Slaney crosses the county from Newtown Barry to Wexford, receiving the Bann from the northward, and affords a perpetual variety of picturesque and romantic views among its wooded and winding banks. This river is navigable to Enniscorthy. The linen manufacture has made no progress in this county, but there is a manufacture of coarse woollens. The chief towns are Wexford, New Ross, and Enniscorthy, of which an account is

given under their names. Wexford has been notorious for the events which took place in it during the rebellion of 1798. In it the misguided populace was successful for some time, and the massacres at Scullabogue, and at the bridge of Wexford, afford a melancholy proof of what may be expected from an ignorant and almost barbarous peasantry, when they have the ascendancy. Their leaders were unable to controul them, and if the king's troops had not been successful, there would have been no bounds to their exterminating phrensy. Before the Union, Wexford had eighteen members, but these have been reduced to four, two for the county, and one each for the towns of Wexford and New Ross. Beaufort.

WEXFORD, a sea-port and post-town, and also the assize town of the county of the same name, in Ireland, at the mouth of the river Slaney. It was originally built by the Danes, who named it Wexford, and it was formerly considered a place of strength, being enclosed by very thick walls, some of which are still remaining. There are some handsome buildings; on the site of the old castle the barracks are erected, commanding an extensive view of the harbour. The church, situated in the main street, is an elegant modern structure. The market and court-house are likewise new edifices; but the chief ornament of Wexford is its wooden bridge, thrown over an arm of the sea, 2100 feet long, where insurmountable difficulties baffled all efforts to form a stone bridge. This bridge is a favourite promenade, and is as delightfully calculated for a pleasant recreation, as it constitutes an useful communication. The harbour, though spacious, is shallow, and formed by two necks of land, between which there is an entrance about half a mile broad, which was formerly defended by two forts, erected at the extremity of each isthmus. The mouth of the harbour is choked with a bar, and therefore no vessel drawing more than twelve feet water can pass to the town. Provisions of all kinds are very plentiful and cheap here, particularly the finest wild fowl. The chief export is corn, principally barley and malt. Wexford was taken from the Danes by the English invaders, after a siege of four days, in 1170; it was besieged and stormed by Cromwell in 1649; and on being evacuated by the king's troops, it was taken possession of by the rebels in 1798. The shocking murder of the loyal inhabitants, when 97 unoffending victims suffered at the bridge, has been already alluded to. There are seven parishes, but they are all united, and have only one church in common. Wexford is 67 miles S. by W. from Dublin. Carlisle. Traveller's Guide.

WEXIO, a town of Sweden, in the province of Smaland, situated on the Helga lake: the see of a bishop, and residence of the provincial governor; 46 miles N.N.W. of Carlscrona. N. lat. $56^{\circ} 52'$. E. long. $14^{\circ} 44'$.

WEY, a river of England, which runs into the Thames at Weybridge. This river is made navigable to Guildford and Godalmin, and a canal has lately been made from it to Basingstoke, in Hampshire.—Also, a river of England, which runs into the sea at Weymouth.

WEY. See WEIGH.

WEYBER, in *Geography*, a lake of Bavaria; 3 miles W.N.W. of Kempten.

WEYBRIDGE, a considerable village in the hundred of Elmbridge, and county of Surrey, England, is situated on the river Wey, whence it derives its name, not far from its conflux with the Thames, at the distance of 12 miles N.E. by N. from Guildford, and 20 miles S.W. by W. from London. It contains some respectable houses, among which is a large edifice, called Holstein-house, from having

been the residence of a prince of Holstein, when on a visit to England; it has for some years been used as a printing-office. The church is a small, but neat structure, having a nave and south aisle, at the west end of which is the vault of the earl of Portmore's family, built up about four feet above the level of the pavement, inclosed with iron rails, but without any inscription. The population return of the year 1811 states the parish of Weybridge to contain 167 houses, and 918 inhabitants.

In this parish is Oatlands, the seat of his royal highness the duke of York. This domain came into the possession of Henry VIII. by an exchange with the family of Rede, for the manor of Tandridge, in the same county. It was settled by Charles I. on his queen Henrietta Maria for her life; and their youngest son, called Henry of Oatlands, was born here. At the Restoration the queen dowager was again put in possession of the estate; and after her death Charles II. granted it to the earl of St. Alban's. In the next century it descended to the earl of Lincoln, afterwards duke of Newcastle, who fixed his residence here, enlarged the park, and made considerable plantations. In the park is a large piece of water, formed by springs which rise in it. Between the house and garden is a grotto, divided into three apartments, in one of which is a bath, supplied by a small spring, dripping through the rock; at the end of it is a copy of the Venus de Medicis, as if going to bathe.

The duke of York purchased this estate of the duke of Newcastle, together with the manors and parks of Byfleet and Weybridge, which he held by lease from the crown. In 1800 two acts were passed for inclosing the common fields and wastes, under which the duke obtained by allotments and purchases about 1000 acres of the waste, so that the domain now comprises about 3000 acres. The mansion was burned down while the duke was in Flanders, in 1793. The present house was then erected, from designs by Mr. John Carter; and in 1804 an act was passed for granting to the duke so much of this estate as was held of the crown.

In a small park in this vicinity is Ham, an old mansion, formerly the residence of the countess of Dorchester, mistress of James II. It is now uninhabited, and in a ruinous condition. Near it are many large cedars; one, in particular, measures, at five feet from the ground, about thirteen feet in circumference, and runs up straight to a great height.—*History and Antiquities of Surrey*. By the Rev. John Manning, and William Bray, esq. 3 vols. folio. *Beauties of England and Wales*, vol. xiv. Surrey. By F. Shoberl.

WEYBRIDGE, a township of the state of Vermont, in the county of Addison, separated from Newhaven by the Otter Creek, containing 750 inhabitants.

WEYDA, a town of Saxony, in the circle of Neustadt, on the Elster; 11 miles E.N.E. of Neustadt. N. lat. $50^{\circ} 42'$. E. long. $12^{\circ} 1'$.—Also, a river of Saxony, which runs into the Elster, 2 miles N. of Weyda.

WEYDEN. See WEIDEN.

WEYDENAU, a town of Silesia, in the principality of Neisse; 8 miles S.W. of Neisse. N. lat. $50^{\circ} 12'$. E. long. $17^{\circ} 2'$.

WEYDENEN, a town of Prussian Lithuania; 3 miles W.S.W. of Pilkallen.

WEYDENHAYN, a town of Saxony, in the margravate of Meissen; 7 miles W. of Torgau.

WEYER, a town of Austria; 2 miles N.E. of Gmunden.—Also, a town of the duchy of Stiria; 6 miles S. of Pruck.

WEYEREN, a town of Austria; 6 miles W. of Gmunden.

WEYERS,

WEYERS, a town of Westphalia, in the bishopric of Fulda; 8 miles E.S.E. of Fulda.

WEYERSHEIM, a town of France, in the department of the Lower Rhine; 6 miles S. of Haguenau.

WEYHER, a town of Austria; 6 miles W. of Bavarian Waidhoven.

WEYHILL, a village of England, in the county of Hants, celebrated for the great annual fair held here for the sale of sheep, hops, &c.; 3 miles W. of Andover.

WEYL, or WYL, a town of Switzerland, belonging to the abbey of St. Gal, and principal place of a bailiwick; 14 miles S.S.W. of Constance.

WEYLANOO, a town of Hindoostan, in Guzerat, on the coast; 20 miles S.E. of Puttan Sumnaut.

WEYMOUTH, or WAXMOUTH, a borough and market-town in the hundred of Uggescombe, Dorchester division of the county of Dorset, England, is situated on the southern coast of England, at the extremity of a beautiful bay, which forms nearly a semicircle, making a sweep of about two miles. The town is 8 miles S. by W. distant from Dorchester, and 128 miles S.W. by W. from London. It received its name from the mouth of the little river Wey, near which it stands, and communicates with Melcombe Regis, to which it is united by a bridge erected in 1770. That the site of Weymouth was known to the Romans is probable from several circumstances; and Mr. Baxter supposes it to have been the Clavinio, which is mentioned in the anonymous Ravennas. In the Saxon ages, however, it is expressly named in a Saxon charter still extant, by which king Ethelred gave a certain portion of land, called by the inhabitants Weymouth (or Wick), near the isle of Portland, to his faithful minister Atere. In the reign of Edward III. the town had become of some importance, the inhabitants being ordered, together with those of Melcombe and Lyme, to send a certain quota of ships for the king's expedition to Gascony. In the 21st year of that reign, Weymouth (for Melcombe is not mentioned, though perhaps included) furnished the king with 20 ships, and 264 mariners, at the siege of Calais, according to the roll of his fleet preserved in a manuscript in the Cottonian Library. In the year 1471, Margaret of Anjou, with her son, prince Edward, landed here from France, in order to restore her husband to the throne. In 1507, king Philip of Castile, with his queen, were driven on this coast, and having run into the port, were detained by sir Thomas Trenchard, till an interview took place between the English and Spanish monarchs, from which the former derived some advantages. In 1588, Weymouth contributed six ships to oppose the Armada, one of which was of 120 tons burthen. During the civil war of Charles I., this town was alternately garrisoned and besieged by the king, and by the parliament's forces. In 1649 the corporation petitioned parliament for an indemnification for the losses they had sustained in the war, and a relief from the burthen of maintaining the garrison; but their request does not appear to have been granted, as a letter was soon afterwards received concerning the "refractoriness of the magistrates." The manors of Portland and Wike, with the ports of *Waimuth* and Melcombe, and the liberties attached to them, were granted by charter of Henry I. to the monks of St. Swithun, Winton; and Henry II. confirmed the port of *Waimue* and the whole land of Melcombe to that establishment, with additional privileges. Weymouth and Melcombe are (as has been observed under MELCOMBE *Regis*) so frequently joined in descents and ancient grants, that some difficulty occurs in separating them with precision. Weymouth is the more ancient borough; though neither sent members to parlia-

ment till the reign of Edward II., since which time each of them returned two. Melcombe, being part of the demesne of the crown, and possessing some peculiar privileges, is principally noticed in succeeding charters. The rivalship which subsisted for centuries between the two boroughs arose, in the reign of Elizabeth, to such a height, that it was judged expedient to unite them; and an act was passed in her 13th year (afterwards confirmed by James I.), by which they were incorporated, and directed hereafter to be called "The united Town and Borough of Weymouth and Melcombe Regis;" the government being vested in a mayor, recorder, two bailiffs, an indefinite number of aldermen, and twenty-four capital burgesses: and they now possess, as one borough, the peculiar right, with the metropolis, of sending four members to parliament. The representatives are elected by the freeholders of Weymouth or Melcombe, whether inhabitants or otherwise. The number of voters is about two hundred. These electors have also votes for the county members. Leland says, "The townlet of Weymouth lyeth strait agayn Milton (Melcombe) on the other side of the haven, and at this place the water of the haven is but a smaule brede, and the trajectus is by a bote or a rope bent over the haven; so that in the ferry-bote they use no oars. Waighmouth has certain liberties and priviledges, but there is no mair in it. Ther is a kay and wharf for shippes. By this town on a hill is a chapel of ease. The parochie church is a mil off." The chapel mentioned by Leland was remarkable for its elevated situation; having, according to Coker's survey of this county, an ascent of eighty stone steps. It was of considerable antiquity, as appears by a patent of Henry VI., granting a licence to found a guild in the chapel of St. Nicholas, in the borough of Weymouth, by the name of the master and wardens of the fraternity or guild of St. George, in Weymouth. This chapel was demolished in the civil war: the site is still called Chapel Hays, and is now used as a bowling-green. Weymouth, since the time of Elizabeth, had, from a variety of causes, been gradually going to decay. The removal of the wool-staple to Poole, the loss of the Newfoundland trade, the havoc made by the civil wars, damages by fire, want of public spirit, and other circumstances, had concurred to produce this effect; and till it began to acquire celebrity as a watering place, it was little more than an inconsiderable fishing-town. The late Ralph Allen, esq. of Bath, about the year 1763, first contributed to bring Weymouth into repute. Having received great benefit from bathing there, he proclaimed its salubrity to the extensive circle of his acquaintance; and his encomium being exceeded by the real beauties of the situation, it soon began to be the resort of the first company from all parts of the kingdom. The reputation thus acquired was extended by the late duke of Gloucester, who, having derived considerable advantage himself, provided a residence for the accommodation of the royal family; and their majesties, accompanied by the three elder princesses, in the year 1789, made their first visit to this place. His majesty experienced its beneficial effects, and became so attached to the spot, that he has repeatedly honoured it with his presence. The advantages arising from these visits have proved of the greatest consequence to the town, which has rapidly augmented in size and importance, from the vast concourse of people by which it is now frequented. The chief objects of curiosity to strangers, are the Esplanade and the Bay. The Esplanade, a fine level piece of sand, which, but a short time ago, was nothing but a receptacle for all the rubbish of the town, is now converted into one of the most charming promenades in England, and adorned by a range of handsome edifices.

This public walk is half a mile in length, and about thirty feet in breadth. The bay, where the company bathe, makes a semicircular sweep of nearly two miles, and is protected from winds by the surrounding hills, which render the sea perfectly secure. As soon as Weymouth became a place of fashionable resort, the expediency of public amusements was perceived; and Mr. Sproule of Bath offered proposals for erecting a set of assembly-rooms, with an hotel, and other necessary appendages. The propositions were acceded to; and about the year 1772, a building, 600 feet in length, and 250 in width, was erected on a vacant spot adjoining the town, at the expence of 6000*l.*, which was defrayed by subscriptions in shares of 100*l.* each. The Royal Assembly Room is a lofty, light, and spacious building, in which upwards of an hundred couples may dance with ease and pleasure. The theatre has been recently fitted up in a style of elegance that does equal credit to the manager and the architect. The boxes are capable of containing 300 spectators; and the mode in which they are decorated is little inferior to the London theatres. On the quay is a most convenient hot salt-water bath. The bridge has been rebuilt in the Chinese style. The church is a low structure, occupying the site of an ancient chapel belonging to the church at Radipole, of which parish this was originally a part, but in the reign of James I. was made a separate jurisdiction; within it is a fine altar-piece, representing the Last Supper, for which sir James Thornhill, who executed and presented it to the town, is said to have refused 700*l.* East of the church are some buildings that are connected with a Dominican priory, founded here about the commencement of the fifteenth century. These are now parcelled out in tenements; and the chapel belonging to the priory is used as a malt-house. The Quakers and Independants have each a meeting-house here. The number of houses in Weymouth, as returned under the population act of 1811, was 447; of inhabitants 1747. Markets are held on Tuesday and Friday; and here are three annual fairs.

Several small forts have at various periods been erected to defend the town and harbour. On a high cliff, about a mile from the town, are the ruins of Sandisfoot castle, a fortress erected by Henry VIII. about the year 1539, when he expected the Papal see to excite an invasion of this country. Leland denominates it, "a right goodly and warlike castle, having one open barbican." Its form was a parallelogram, the greatest length running from north to south. The walls, which were mostly cased with squared Portland stone, were lofty and very strong: in some places, the thickness was not less than seven yards.—Hutchin's History of Dorsetshire, 3 vols. folio. Beauties of England and Wales, vol. iv. Dorsetshire. By J. Britton, and E. W. Brayley, 1804.

WEYMOUTH, a town of New Jersey, in the county of Gloucester, containing 1029 inhabitants.

WEYMOUTH, or WASSAGUSSET, a town of the state of Massachusetts, in the county of Norfolk, containing 1889 inhabitants. This is said to be one of the oldest towns in the state. It lies on the coast, and has some small vessels employed in fishing. The cheese made in its environs is much esteemed; 5 miles S. of Boston.

WEYMOUTH Bay, a bay on the N.E. coast of New Holland, to the N.W. of Cape Weymouth.

WEYPERT, a town of Bohemia, in the circle of Saatz; 25 miles N.W. of Saatz. N. lat. 50° 25'. E. long. 13°.

WEYS, a river of Austria, which runs into the Danube, a little to the E. of Ips.

WEZE, a river of France, which runs into the Meuse at Liege.

WHALE, in *Astronomy*, one of the constellations. See CETUS.

WHALE, *Cete*, in the Linnæan system of *Zoology*, the seventh order in the class of *mammalia*. For the characters and distribution of this order, see CETE.

For the discriminating characters of the genus of *balæna*, or whale, and a general account of its species, see BALÆNA.

The common whale, or *balæna mysticetus* of Linnæus, with its variations, &c. is described under the article MYSTICETUS. Aristotle is said to have given it the name of *mysticetus*, *μυστικητος*, or bearded whale, from its having in its mouth hairs instead of teeth.

In old time the whale seems never to have been taken on our coasts, but when it was accidentally flung on shore: it was then deemed a *royal fish*; and the king and queen divided the spoil; the king asserting his right to the head, and the queen to the tail. The reason of this whimsical division, as assigned by our ancient records, was to furnish the queen's wardrobe with whale-bone.

The anatomy of the bones of the whale has been so little understood, that there have been many very great errors in regard to such of them as have been at times found fossil, or buried in the earth among the teeth of elephants, and the remains of testaceous and other animals. The most frequent and most ridiculous of all the wrong opinions about these, is their having originally belonged to creatures of the human species; yet many, even among the more intelligent part of the world, have taken them for the remains of giants. The vertebræ of a whale have been mistaken for those of a giant, and a part of its fins for a hand, and so of the rest. While the world, more ready to spread the marvel, than to enquire into the truth, have made computations of the height of the man to whom bones of that size must have belonged, and from their proportion in regard to those of the common human size, have found the giant who possessed them must have been 90 or 100 feet high; much less pains in comparative anatomy would have taught them, that they never could have belonged to any human body at all. Mem. Acad. Par. 1727.

WHALE, *Beaked*, *Bottle-head*, or *Nebbe-haul*, *Balæna Roftrata*, the small whale, with taper snout, and adipose back fin, or with very long and acute beak or snout. The head, upper part of the back, fins, and tail, are of a dark or blueish-brown; and the sides and abdomen are of a beautiful white, with a slight tinge of pale rose or flesh colour; and marked for more than half the length of the animal by numerous longitudinal plaits or furrows: the eyes are small, as is also the head, and the snout is more elongated than in any other species, tapering gradually to the extremity, which is slightly pointed; the back fin is small, and situated at no great distance from the tail; the pectoral fins are small and narrow, and the tail is divided into two longish and pointed lobes. This is of a more elegant form than those of the larger species. These fish sometimes, but rarely, grow to the length of twenty-five feet; they make little noise in blowing, are very tame, come very near the ships, and will accompany them a great way.

WHALE, *Fin-back*, *Balæna Physalus* of Linnæus, called also *fin-fish*. See PHYSALUS.

WHALE, *Pike-headed*, *Balæna Boops* of Linnæus, is a species which takes its name from the shape of its nose, which is narrower and sharper-pointed than that of other whales. The length of one taken on the coast of Scotland, observed by sir Robert Sibbald, was forty-six feet, and its greatest circumference twenty; but it sometimes exceeds this length. From the skinny flap at the root of the tongue, as well as from

from the intestines, the Greenlanders prepare windows. See **BOOPS**.

WHALE, *Round-lipped*, or *Broad-nosed*, or *Under-jawed*, *Balæna Musculus* of Linnæus, is characterized by having the lower lip broader than the upper, and of a semicircular form. See **MUSCULUS**.

WHALE, *Bunched*, *Balæna Gibbosa* of Linnæus, with one or more gibbous excrescences on the back, and without dorsal fins: the *Knottensfisch* oder *Knobbelfisch* of Anderfon and Crantz. This species is a native of the Northern seas, and though not much known, is said to be of the same general form with the great whale, but of smaller size, and having its back furnished with one or more tubercles. The variety with a single tubercle is found about the coasts of New England; the other with six tubercles along the back is supposed to swarm about the coasts of Greenland. Their whale-bone is said to be of a pale or whitish colour.

WHALE *Spermaceti*. See **CACHALOT**, **PHYSETER**, and **SPERMACETI**.

See on the subjects of the preceding articles, Pontopidan's Nat. Hist. of Norway, vol. ii. p. 118, &c. Crantz's Hist. of Greenland, vol. i. p. 106, &c. Pennant's Brit. Zool. vol. iii. p. 50, &c. Phil. Trans. abr. vol. viii. p. 424, &c. Shaw's Zoology, vol. ii.

WHALE-Blubber, in *Agriculture*, the fat oily refuse matter left in making the oil from that fish. It is a material which has been used as a manure in some cases with success, especially when employed in mixture with clayey loam, sandy loam, or any other common earthy or mouldy substances. These matters should be blended together in such a manner, it is said by the writer of the "Elements of Agricultural Chemistry," as to expose a large surface to the action of the air, the oxygen of which produces soluble matter from them. It is observed, too, that lord Somerville made use of this oily substance with great success on his farm, in the county of Surrey; in which case it was made into a large heap with soil, and retained its powers of fertilizing for several successive years.

It is noticed, that carbon and hydrogen abounding so much in this as well as other oily substances, fully account for their effects; and that their durability is easily explained from the very gradual manner in which they change by the action of the air and water on them, as must obviously be the case.

This fatty material, in this sort of union with earthy matters, may consequently be a very beneficial application in many cases of tillage-land, especially where the superficial bed of mould or soil is rather of the thin kind. It may also be very useful as a top-dressing to grass-land, particularly where the sward is thin, tender, and not well set with grassy herbage, as tending not only to promote the growth of the crops, but the closeness and firmness of the surface swardly covering. See **MANURE**, and **OIL Compost**.

It should therefore be preserved and procured as much as possible for these uses and applications.

WHALE-Bone, a commodity procured from the whiskers of the whale, used as a stiffening in stays, fans, buxks, screens, &c. See **WHALE supra**.

Frederick Martens has particularly described the whale-bone and the method of procuring it in his "Voyage to Spitzbergen." Within the mouth of the fish is the whale-bone, hairy as a horse's hair, and hanging down from both sides, all about his tongue. In some whales the whale-bone is bent like a scymitar, and in others like a half-moon. The smallest whale-bone is before in his mouth, and behind towards his throat; and the middlemost is the largest and the longest, being sometimes about two or three men's length. On one

side, all in a row, there are 250 pieces of whale-bone, and as many on the other, containing in all 500; and there are still many more, for the cutters let the least of all remain, because they cannot easily come at it to cut it out, on account of the meeting of the two lips, where the space is very narrow. The whale-bone is in a flat row, one piece by the other, somewhat bending within, and towards the lips every where like a half-moon. It is broad at the top, where it sticks fast to the upper lip, every where overgrown with hard white sinews towards the root, so that between two pieces of whale-bone you may put your hand. These white sinews are of an agreeable smell, break very easily, and may be boiled and eaten. Where the whale-bone is the broadest, as underneath by the root, there groweth small whale-bone, the other being greater. The small whale-bone, as Mr. Martens supposes, does not grow bigger; from one end to the other it is equally thick, and full of long jacks, like horse's hair. The whale-bone is underneath narrow and pointed, and all overgrown with hair, that it may not hurt that which is young; but without the whale-bone has a cavity, for it is turned like a gutter, in which the water runs, where it lies the one over the other, like the shields or plates of craw-fish, or the pantiles of an house, that lie one over the other; for otherwise it might easily wound or hurt the under lip. To cut the whale-bone out is a particular operation, and many iron tools are used for this purpose. Some whale-bone is of a brown, black, or yellow colour, with streaks of several colours. The whale-bones of some whales are blue and light-blue, which latter are supposed to come from young whales.

WHALE-Fins, a name improperly given to whale-bone.

WHALE-Fishery. See **FISHERY**.

WHALE OIL. See **OIL**.

Mr. Parkes (Essays, vol. i.) observes, that the dealer in Greenland whale oil might also increase the profits of his trade very much, by preparing his oil for sale when the weather is suitable for the operation. This kind of oil is always purified by passing it through large flannel bags, which retain the impurities, and suffer the finer parts to percolate through them. When the oil has undergone this treatment, it is called *bagged* oil, and is then deemed fit for sale. At a low temperature, a considerable quantity even of this latter kind would concrete, and might be separated by similar means; whereas in a warm atmosphere this dissolves, and, being less inflammable, very much injures the oil for burning.

By proper attention to this circumstance, all the oil which is designed for burning might be very much improved, and the portion thus separated from it, would be worth more to the soap manufacturer for making yellow soap, than similar oil which had not undergone this process.

This intelligent chemist conceives, that an oil-merchant would do well always to bag different oils in different seasons; though many experiments might be necessary before it could be ascertained what was the exact temperature at which the respective kinds would most copiously deposit this feculence. After observing that in several parts of Germany, and particularly in the neighbourhood of Gottenburgh, ammonia is prepared from the dregs which remain after the expression of train-oil, he suggests that whale-blubber might be employed for the distillation of ammonia. Madder, he says, might be devised for correcting its offensive smell, and rendering it very productive of volatile alkali. See **AMMONIA**.

WHALE Bank, in *Geography*, a fishing-bank on the coast of Newfoundland, 60 miles long, and 21 wide; 90 miles S. of Cape Mary. N. lat. 45°. W. long. 53° 50'.

WHALE Cove, a bay of the Atlantic, on the north coast of the island of Manan, near the coast of Maine.

WHALE Fish Island, an island on the coast of Guiana, at the mouth of the river Essequibo.

WHALE Island, a small island in the North sea. N. lat. $69^{\circ} 14'$. W. long. 134° .—Also, a small island near the north-west coast of Borneo. N. lat. $4^{\circ} 10'$. E. long. $112^{\circ} 21'$.

WHALE Islands, small islands in Portsmouth harbour. N. lat. $50^{\circ} 48'$. W. long. $1^{\circ} 5'$.

WHALE Point, the south-east cape of an island in the straits of Magellan; 6 miles S.S.W. of Passage Point.

WHALE Rock, an under-water rock at the entrance of the Bay of Islands, on which the Endeavour struck in 1769; 4 miles S.E. of Point Pocock.

WHALE Sound, a channel in the straits of Magellan, between an island and the coast of Terra del Fuego.

WHALFIRTH VOE, a bay on the west coast of the island of Yell. N. lat. $60^{\circ} 58'$. W. long. $1^{\circ} 25'$.

WHAME, in *Natural History*, the name given by the people of some parts of England to the burrel-fly, or wringle-tail, a species of bee-fly very troublesome to horses.

WHANG-HO, in *Geography*. See HOANG-HO.

WHAPLODE, a township of Lincolnshire; 2 miles S. of Holbeach.

WHAPPING'S CREEK. See WAPPING'S Creek.

WHARF, a perpendicular building of wood or stone, raised on the shore of a road or harbour, for the convenience of landing or discharging a vessel, by means of cranes, tackles, capsterns, &c. See *Artificial PORTS*.

The fee paid for the landing of goods on a wharf, or for shipping them off, is called *wharfage*. And the person who has the oversight or direction of the wharf, receives wharfage, &c. is called the *wharfinger*.

There are two legal denominations of wharfs, *viz.* legal quays and sufferance wharfs.

Legal quays are certain wharfs in all sea-ports, at which all goods are required, by the 1 Eliz. c. 11., to be landed and shipped (except at Hull); and they were set out for that purpose by commission out of the court of exchequer, in the reign of Charles II. and subsequent princes. Others have been legalized by act of parliament; as the London docks, by 39 & 40 Geo. III. c. 47.; West India docks, by 39 & 40 Geo. III. c. 69. and 42 Geo. III. c. 113; East India docks, by 43 Geo. III. c. 126. and 46 Geo. III. c. 113. (See *DOCKS*.) Hull, by 14 Geo. III. c. 56. and 42 Geo. III. c. 191.; Milford, by 30 Geo. III. c. 55.; Bristol, by 48 Geo. III. c. 11.

In some ports, certain wharfs are deemed to be legal quays by immemorial practice, though not set out by commission, or legalized by act of parliament; such as Chepstow, Gloucester, &c.

Sufferance wharfs are places where certain goods may be landed and shipped; such as hemp, flax, raff, and other bulky goods; likewise goods carried coastwise, in Great Britain, by special sufferance granted by the crown for that purpose.

The constituting limits to the ports and legal quays is part of the royal prerogative. Lord Hale's Treatise. *Vide* Hargrave's Tracts.

WHARF also, in a canal, denotes that wider part of it where boats lie while loading or unloading.

WHARFAGE, in *Commerce*, certain rates paid for landing and shipping goods from the quays.

WHARFE, or **WHERFE**, in *Geography*, a river of England, in the county of York, which runs into the Ouse, 7 miles below York.

WHARFINGER, the proprietor or farmer of the quays where goods are shipped and landed.

By the 26 Geo. III. c. 40. no goods entitled to drawback or bounty on exportation are to be shipped in Great Britain, but by wharfingers licensed by the commissioners of the customs; and in docked lighters. And they are to give bonds not to be concerned in illegally landing, relanding, or shipping goods. They are also liable to certain penalties at conniving or knowing of any fraudulent transaction, or landing goods at improper places and times, by 1 Eliz. c. 11., and 13 & 14 Cha. II. c. 11.

WHARTON, HENRY, in *Biography*, an English divine of the Established Church, was born in 1664, at Worstead, in Norfolk, where his father was vicar; and in his sixteenth year admitted a pensioner of Gonville and Caius college at Cambridge, where he assiduously pursued the study of various branches of literature, and particularly of mathematics, under Isaac Newton, Lucasian professor. After taking the degree of B.A. with great reputation, he assisted Dr. Cave in his "Historia Literaria," contributing almost the whole of the appendix of the three last centuries. In 1687 he took orders, and his degree of M.A. in the following year. He had various literary occupations, chiefly in writing or editing treatises against Popery; until he took priest's orders, when he was presented first to the vicarage of Minster in the isle of Thanet, and in 1689 to the rectory of Chartham. By the advice of Dr. Lloyd, bishop of St. Asaph, he undertook the work which gave some celebrity to his name, intitled "Anglia Sacra, sive Collectio Historiarum, partim antiquitus, partim recentior Scripturarum, de Archiepiscopis et Episcopis Angliæ à prima Fidei Christianæ susceptione ad Annum 1540," 2 vols. fol. London, 1691. An additional part was published after his death in 1695, under the title of "Historia de Episcopis et Decanis Londinensibus; necnon de Episcopis et Decanis Asslavenfisibus (St. Asaph); à prima Sedis utriusque Fundatione ad Annum 1540," 8vo. The author's "Anglia Sacra" was the result of great industry and labour, and evinces the author's zeal for the church to which he belonged; but it is chargeable with incorrectness. In 1692 he published "A Defence of Pluralities;" in the following year he edited some ancient theological pieces; and, under the name of Anthony Harmer, published "A Specimen of some Errors and Defects in the History of the Reformation of the Church of England, by Gilbert Burnet, D.D.," a work which excited the indignation of the author, and caused him to mention Wharton with asperity in the introduction to the third volume of that work. The last publication of Wharton was "The History of the Troubles and Trial of Archbishop Laud;" to which were added Laud's diary, and some other pieces. He also edited the Life of Cardinal Pole, by Bacatelli, together with some animadversions on Strype's Memorials of Archbishop Cranmer. Although his constitution was strong, he closed his life, in consequence of intense application, somewhat prematurely, in March 1694-5, in the 31st year of his age, leaving several MSS., some of which were afterwards printed, as also two volumes of sermons. He was interred in Westminster-abbey. *Biog. Brit.*

WHARTON, PHILIP, *Duke of*, the son of the marquis of Wharton, who was a firm supporter of the Revolution and Hanover succession, was born in 1699; and after having exhibited talents which commanded notice, when he was 13 or 14 years of age, in the course of his education under domestic tutors, contracted a premature marriage with the daughter of major-general Holmes, and thus disappointed his father's views, and hastened his death in 1715. In the beginning of 1716, Philip set out on his travels, proposing to finish his education at Geneva; but the young marquis, having contracted a taste for gaiety and expence,

was disgusted with the manners of that place, and leaving his governor there, proceeded to Lyons, and wrote to the Pretender at Avignon, accompanying his letter with the present of a fine horse. The Pretender was highly gratified, and receiving the marquis at his court, decorated him with the title of the duke of Northumberland. At Paris he paid his respects to the dowager-queen of James II., and received notice and good advice from the English ambassador, lord Stair. About the end of 1716 he returned to England, and going over to Ireland, where he possessed a peerage, he was admitted to take his seat in the house of lords of that kingdom. Here, deserting the principles and connection which he had lately formed, he defended the established government with all the powers of his reasoning and eloquence; in consequence of which he was advanced to a dukedom, by the style of duke of Wharton, in the county of Westmoreland. Upon coming to age, he took his seat in the English house of lords, where he distinguished himself by an abandonment of his lately avowed principles, in the defence of bishop Atterbury; and he also published a virulent opposition paper, intitled "The True Briton." But such was his boundless extravagance, that his estate was vested, by a decree of chancery, in the hands of trustees, who allowed him an annuity of 1200*l*. Having only this pittance, he determined to live abroad, and to enter into the service of the Pretender. Having visited Vienna and Madrid, he formed an acquaintance at the latter place with a young lady of Irish extraction, who was maid of honour to the queen of Spain, and married her; his duchess having died in 1726, without leaving any issue. From Rome, where he appeared under the title of the duke of Northumberland, and decorated with a blue ribband and garter, he returned to Spain, and obtained permission from the king to go as a volunteer to Gibraltar, which was then under siege by the Spaniards. When this siege broke up, he visited the Spanish court, and was nominated by the king "colonel-aggregate" of one of the Irish regiments. Discouraged in his wishes to be actively employed in the service of the Pretender, he went to Paris, and with singular effrontery paid a public visit to the English ambassador, Horace Walpole; informing him, upon taking leave, that he was going to dine with the bishop of Rochester, though it had been made criminal to hold any communication with that exiled person. At this time a bill of indictment for high treason was preferred against him in England, for having appeared in arms against his majesty's fortresses at Gibraltar; but a wish to reclaim him induced sir Robert Walpole to send two friends to offer him his re-establishment and the possession of his estate, if he would only sue for pardon. This he refused to do, consenting only to accept a pardon if freely granted him. His allowance from home was discontinued, and he was overwhelmed with debts abroad. From Rouen, where he had for some time resided, he removed to Paris, living meanly, and providing for himself by various dishonourable expedients. Having obtained a small sum, when all his resources had failed, he took his duchess with him, and went by water to Bilboa. From thence he proceeded to join his regiment, subjecting his duchess to extreme distress, in which she was occasionally relieved by the bounty of the duke of Ormond, who was himself an exile. In 1730 his health declined, and he amused himself in composing a tragedy, on the story of Mary queen of Scots; but his end was approaching. In his way to a mineral spring, in the mountains of Catalonia, where he had once obtained relief, he was obliged to stop at a small village, when his condition was so pitiably destitute, that the fathers of a Bernardine convent took compassion upon him, and brought him to their house, where by atten-

tion and cordials his life was prolonged for about a week. At length, without a friend or acquaintance to close his eyes, having performed the last duties of penitent devotion, he expired on May 31, 1731, in the 32d year of his age, and was interred the next day after the manner of a poor monk. Pope has recorded his character, in the first epistle of his *Moral Essays*, in the following beautiful lines:

" Thus with each gift of nature and of art,
And wanting nothing but an honest heart;
Grown all to all, from no one vice exempt,
And most contemptible to shun contempt;
His passion still, to covet general praise;
His life, to forfeit it a thousand ways;
A constant bounty which no friend has made;
An angel tongue which no man can persuade;
A fool, with more of wit than half mankind;
Too rash for thought, for action too refin'd;
A tyrant to the wife his heart approves;
A rebel to the very king he loves;
He dies, sad outcast of each church and state,
And, harder still! flagitious, yet not great."

Wharton was one of the warmest patrons of Young, who dedicated to him his most celebrated tragedy "The Revenge," and gave him the credit of having suggested the most beautiful incident in that composition. *Biog. Brit. Pope's Works. Johnson's Lives of the Poets.*

WHARTON, THOMAS, a physician and anatomist, was born in Yorkshire, in 1610, and educated at Pembroke-hall, Cambridge. Before the civil wars he resided in Trinity college, Oxford, as private tutor to a natural son of lord Sunderland. Upon the commencement of the war, he removed to London, and engaged in the practice of physic. After the surrender of Oxford to the parliament in 1646, he returned to Trinity college, and was created M.D. by the recommendation of general Fairfax. Returning again to London, he became a member and censor of the college of physicians, and acquired considerable practice and reputation. In 1652 he read lectures before the college on the subject of the glands; but labouring, as other anatomists of that day did, under a scarcity of human subjects, he was under a necessity of availing himself of animal dissection. In his work, intitled "*Adenographia, five Glandularum totius Corporis Descriptio*," 1656, 8vo., his descriptions are almost wholly taken from brute animals, and therefore cannot stand the test of modern accuracy. Nevertheless he revived and improved the knowledge of the salivary ducts on the side of the tongue, to which he affixed his own name; and he furnishes useful observations on the diseases of the glands. He died in 1673. *Haller. Gen. Biog.*

WHARTON, in *Geography*, a township of Pennsylvania, with 922 inhabitants; 30 miles S. of Pittsburgh.

WHATLY, a town of Massachusetts, with 891 inhabitants; 10 miles N. of Northampton.

WHATOGA, a town of United America, in the Tennessee state; 40 miles S. of Knoxville.

WHEAT, in *Botany*. See TRITICUM.

WHEAT, in *Agriculture*, a well-known valuable grain, much cultivated and grown in many parts of this as well as most other countries, as being the principal sort of corn from which bread is made. It is not now well known from what country wheat was first introduced into this; but it has lately been suggested as probable, by sir Joseph Banks, in consequence of having a small paper of seeds, on which were written *Hill wheat*, put into his hands, the seeds contained in which were found to be scarcely larger than those of our wild grasses; though, when nicely examined, they perfectly

WHEAT.

perfectly resembled grains of wheat, and which on being sown in a garden very unexpectedly proved to be wheat of the spring kind, and the usual size, the grains of which being nearly, if not wholly, as large as those of the ordinary wheat of the above sort, that the packet and seeds came either from the peninsula, or from the hilly country, far within land from Bengal, as that province itself is a flat alluvial tract of land, entirely level. That as this hill wheat is, however, no doubt, it is supposed, known to some persons who are now either in India, or who have lately returned from thence into this country, it is certainly a matter of some importance to know what information they can give on the subject of it, especially whether this wheat be a cultivated, or a wild plant; as we shall, it is said, if the latter be the case, ascertain two of the greatest desiderata of cultivators; as those of the country where wheat grows spontaneously, and the nature of the grain in its original state, when unassisted by the fostering hand of man.

It is by no means improbable, from the nature and habits of wheat, that it may have come originally from the hilly country of the east, and been rendered hardy by time and cultivation in this and most other parts of the world.

Wheat is a kind of grain of which there are two different species, in cultivation as crops, in the climate of this country; as the common *smooth* or *polled* wheat, and the *cone rough* or *bearded* wheat. Of the first of these sorts, which is by much the most cultivated in this kingdom, as being the most suited to the nature and quality of the largest extent of the soils or lands in it, and as affording the finest kind of flour, there are numerous varieties that are differently preferred in different situations; and the latter species, which is often termed *riquet* wheat, and which has also several varieties that differ little except in the colour of the chaff and the form of the ears, though it does not afford the finest sort of flour, as yielding the largest quantity of produce on stiff moist clayey lands, and as being less subject to injury and disease from wetness on such soils, as well as less liable to lodge from its firmness of stem, is frequently cultivated and grown on such sorts of land.

It has been observed by an able and intelligent cultivator in the county of Kent, Mr. Boys, that the number of sorts of this grain is annually increasing by importation from foreign countries. But that the *old* sorts are the *brown* and *yellow lammas*, the *white straw*, *Fulham*, and the *white* or *egg-shell*. That the *brown lammas* was the kind chiefly cultivated in that county till within these twenty or thirty years; but that it has now given way to a variety of new kinds, as well as some of the other old sorts: experiment has, however, shewn it to be the least productive of the several sorts. It is the common *brown-strawed wheat* that grows with a long jointed ear, the chaff of a dark brown colour, the straw long and apt to fall, the hull or bran thin, the flour very white, and the corn mellow in grinding, for which reason it is esteemed by the millers as the best of the *old* sorts for their use; and that the *yellow lammas* resembles the *brown*, in every respect, except that the colour of the grain is of a yellow hue, and the chaff of a somewhat lighter colour than the others. A red lammas with a red straw, red ear, and red kernel, is noticed by Young as being reckoned by many farmers the best of all the sorts hitherto known, as yielding the finest and whitest flour. The first of these writers states, that the *white-strawed wheat* takes its name from the colour of its ear, and in other counties has the title of the *Kentish white straw*. That it sends out a greater number of stems from the stool or plant than the other sorts, and in that way is often a very thick crop on the land. That the straw is generally somewhat shorter than that of many

other sorts, and not quite so liable to fall in rainy seasons. That it is on these accounts much sown in the eastern parts of that county; but that from its dull colour, its having a thick bran, and often grinding very steeply, it is not much approved by the millers of the district. It is remarked, that the *Fulham* sort produces a white straw, which grows short and coarse; but that it is very productive, particularly on poor land: the grain is however coarse, and the bran thick, which circumstances render it the least valuable to the millers of any of the sorts described above. And that the *white* or *egg-shell* wheat is known by its producing a white straw, a smooth white chaff, and very white grain: the bran of which is very thick, but the flour remarkably white. It works mellow in grinding, is very early ripe, and so free in the ear as to blow out in windy weather, which is a disadvantage.

It is noticed, that of the *new* sorts of wheat in that county, as the *hoary white*, the *nonpareil*, the *pilbeam*, the *square ear*, the *hoary brown*, and the *hoary white*, called by some the *velvet-eared*, the last is by far the most valuable, as being very productive, and the best for the miller's use. It has the straw white and short, the chaff covered with a thick fine down, somewhat of a brownish hue; the grain remarkably small, and of a dull white colour, the bran very thin, so that the grain in some cases is almost transparent when held up to the light. It grinds very mellow, and makes a beautiful fine white flour. But from the quantity of the down upon the chaff, and its small ears binding up very close in the sheaf, it is apt in a rainy season to vegetate too freely in the field; on which account it is not so proper to cultivate in a moist climate, and in small inclosures that are not open to the influence of the sun and winds. That the *nonpareil* is a sort said to have been brought into this country from America: it has a bright straw, with a brown ear; and the grain is very white, large, and plump. It is very productive on all soils, thrashes very free, and yields in that operation the greater part of its chaff; thereby producing a great quantity of horse-meat. It grinds very mellow, and is well esteemed by the millers in most districts. And that the *pilbeam* is a brown wheat growing very stiff, and is generally thick on the land. The grain is small and plump, somewhat of a yellow-brown. It is accounted very productive on rich lands, and is a valuable kind to mix with others, but will not of itself make good bread, from its not fermenting or working properly in that operation. In regard to the *square-eared wheat*, that it is a very productive sort, but is apt to drop out in the field, before it is ripe, and in gales of wind, on which account it is not so much cultivated. And that the *hoary brown* is but lately introduced, consequently little known at present. And the *hoary white* sort, which has a white straw, ear, and grain, is in much the same situation. That the *Clarke-wheat*, which has a red blossom, chaff, and straw, but white grain, is much cultivated in Suffex. That the *hedge wheat* is also white and very productive. And that the *velvet wheat* is distinct from the hoary white, but is white, not weighty, yet affording much flour, being very thin in the skin.

There are also different varieties of cone or bearded wheat, a sort which is named from the form of the ear, as has been seen above. That of the *riquet wheat*, there are two sorts, the white and the brown, neither of which are much cultivated in Kent. They both ripen late in the season, and are so coarse and steeply, as to be unfit for making bread, unless mixed with a large proportion of a better sort of flour. They, however, produce very abundant crops on strong wet lands, as has been noticed. It is remarked, too, by Mr. Young, to be a productive sort on very poor, wet,

cold land, though a coarse grain, selling at an inferior price in the markets. And the bearded or rivet kind of wheat is likewise thought, by some cultivators, to be the most adapted to such kinds of rich lands as have been newly broken up, and where there may be danger of the crop lodging from too great luxuriance, as it possesses the property of a greater firmness of straw or stem than the common kinds, as suggested above.

The white and the red are the sorts the most esteemed in general among the polled kind; the former affording the whitest flour, but the latter has the greater produce in most cases.

It is observed, that of the several sorts of wheat that are in cultivation in the county of Suffex, the velvet-eared is preferred in the weald part of it, as having by much the thinnest skin: they there call it *stuffed*. It weighs on the average from fifty-nine to sixty pounds the bushel. It is said by the best judges that the *white stuff* on good land answers best, as being the most saleable: but that on poor land, subject to poppies, the strong-strawed sort that overpowers this weed should certainly be sown.

There is a sort of wheat that obtains much on the Down parts, which is what they call Clark wheat. It is not bearded; has a red blossom, red chaff, and red straw; white grain, as already seen; the sample coarse, being in price under the finest sorts. It is, however, a great yielder, and requires to be cut forward.

The *Chidham white* or hedge wheat is much in cultivation, being introduced by Mr. Woods of this district. Upon trial it is found to be a very fine sort: it is white, of a very fine berry, and remarkably long in the straw. It is now much grown in many of the southern as well as northern counties.

In the county of Essex, according to the Corrected Report on the Agriculture of that district, Mr. Kemp of Hedingham compared wheat from Italy, from Scotland, and from Dantzic; the last by far the best, and next the Scotch; but the Italian was full of smut in spite of every attention in brining and liming; and sowing it a second time with still more precaution, the result was the same.

About Burnham, some cultivate a sort of wheat from Italy, which they approve of much; the straw is remarkably stout and stiff. They cultivate also a sort called the *Sopsodite*; red grain, red chaff, and purple straw; this is a very good sort. The Taunton Dean, too, is beautiful, but will not bear rough weather. For two years past the Hamburgh white, with white grain, and white chaff, has been a fashionable sort; the white American sort is also used.

The sorts most usually sown about Kelvedon are the *burrel red chaff*, and red grain; and the *white rough*; white chaff, and white grain, the chaff rough: this sort stands the weather well, and does not shell easily; but is rather difficult to thrash. About Langenhoe they generally sow white wheat on heavy land, and rarely rivets, *rough chaff*, *York white*, also *American red*. Some other of the above sorts are likewise in use.

It is remarked that a few years ago, as a person at Bradfield was walking through his wheat-fields when the corn was in full blossom, he was struck with the variety of hues, or colours, which the blossoms assumed: at first he conceived it might be owing to the different stages of forwardness in the blossom; but on particular examination and more mature reflection concluded that they were certain signs of a specific difference in the quality of the wheat: impressed with this idea, he selected the ears of different hues, and particularly marked eleven distinct numbers; noting very minutely their characteristic qualities and appearances in the field.

These he gathered and kept separate when ripe, and planted them apart from each other in his garden; the same characteristic difference was observed to continue upon the several numbers when growing in the garden as was observed in the field the preceding summer, and are as below.

First year in the garden culture.—No. 1. A stiff straw, thick ear, the rows or chests in which set closer than in any other.

2. Dark straw, full blade, and large open ear.
3. A large long ear, ripened late, and well set.
4. Full foliage, and a long open ear.
5. Straight handsome straw, large well-set ears, flag or leaf small.
6. Red rusty leaf before spindling, red straw with little leaf at harvest and smaller ears than any.
7. Very like No. 6. in straw, the ears small, but well set.

8. Straw leafy at harvest, of a good colour, well eared and handsome.

9, 10. Straw full of flag or leaf at harvest, ears set wide.

11. Very like No. 5.

Second year in the garden culture.—No. 1. Short upright stiff straw, thick well-set ears, and later by four or five days than any of the others.

2. Very dark straw, upon which there remained a full dark blade at harvest; long open ears.

3. Strong leafy straw, of a good colour, with a thick long ear, well set, rather later than Nos. 5, 8, and 11.

4. Thick leafy brown straw, with a small ear.

5, 8, 11. Short handsome bright leafy straw, ears long, thick and well set.

6. Long straw with a good deal of flag, ears ill set and open.

7. Straw handsome, but small ears, and subject to root-falling.

9, 10. Long weak straw, very leafy, and subject to root-falling.

It is noticed on these, that the lemon-coloured blossom was observed to attend Nos. 5, 8, and 11; but the colour of Nos. 1 and 3. was not particularly remembered. These are the numbers which had been preserved, Nos. 5, 8, and 11, coming to the sickle about a week earlier than Nos. 1 and 3, the produce of which, when compared with the rejected numbers, is an excess of from six to eight bushels per acre, and weighing about three pounds more to the bushel.

At Bradwell, it is observed, a crop of *Windfor* wheat was had, white grain, white straw, and white chaff, which was a most beautiful sample; the strength of the straw middling.

That of all the different sorts of wheat Mr. Hardy has tried on his farm, the best has been the white egg-shell, and this is the sort most cultivated in Foulness island.

That the *red American* is a sort which yields remarkably well with some; it is much approved in Mersea isle. Some have had the best success with it. But Mr. Strutt, at Terling, sowed a barrel of remarkably beautiful wheat from New York, in part of a field, the rest of which was sown with English wheat, and the American was so blighted in the ear as to produce a poor and miserable grain both in quality and quantity. He sowed it again, and the result was the same, and repeated the experiment the third time, the result again the same, though the adjoining English wheat in all the three years produced a fair crop free from all blight. The *habit* of this wheat, therefore, was not, it is said, changed in three years sowing.

That the *rough chaff*, a white chaff and white grain, with

WHEAT.

a velvet ear; is found about Burnham to be an excellent sort; for there they are subject to strong easterly winds, and it does not shell easily. But some, however, do not like it on heavy land, as it has not straw enough; and think that it should stand till ripe, or it will not thrash well.

And about Hallingburg Rife, and indeed through all the district of the Roodings, they find the *rivet* sort a very useful wheat, which is very general, and is found to yield on that heavy soil much better crops than any common sort; but on lighter soils the Kentish red.

In Norfolk about Reddlesworth they have an opinion that *red wheat* will not answer on black sand, white succeeding to much better advantage. But at Winborough red is only sown by Mr. Salter, the white sorts not answering so well on the heavy soils: it is termed the *old red*. Some prefer the *red chaff*, or red wheat to the white, as being less liable to grow at harvest; white however is a better sample, and produces a better price.

In Hertfordshire the rivet or bearded sort is the common sort on the clays and strong loams about Sawbridgworth, on which it yields more abundantly than the red and white wheats, four or five quarters *per acre* not being uncommon in favourable years. And a sort termed *polled rivets* is also very productive, one hundred grains having been seen in an ear.

About St. Alban's, *Day's stout*, which has the ears growing with four sets of kernels, is much sown: also about Hitchin, where it was discovered by a poor labourer who gathered a few ears. It is said to yield well. It is supposed to be the *pirks* of Ellis. The *red lammas* and *Luswell*, brought from Cambridgeshire, are likewise much sown. On the Albury clays the rivets are grown, yielding largely, but subject to mildew, and selling badly with indifferent straw. They have a *blue* and *white* sort; the latter is preferred.

In most other counties, the same sorts of wheat are likewise cultivated and grown with some other varieties.

In addition to these, there is, however, another species or sort of this grain, which is now much cultivated in some cases, as that which is known by the name of spring-wheat. This is a sort of wheat that is capable of being put into the ground at the same time with other grain crops, in the early spring months. The cultivation of it has been long practised, in some degree, in both the northern and southern parts of the island; but of late a much greater attention has been bestowed upon it, and at present it is raised and grown to considerable extent in different districts and places, as in the fens of Lincolnshire and Cambridgeshire, in many parts of Oxfordshire, in some instances in Berkshire, in Hertfordshire, where it is found to answer well, and in most of the other southern counties, as well as in many parts of the north of England, and even in the lower parts of Scotland.

The common autumn or winter sort of this grain is in general most suited to the heavier descriptions of mellow soils, which do not retain too much moisture. They should however be of a fertile quality, and capable of affording a fine surface mould, for the reception of the grain. But good crops may be raised on the lighter sorts; though the introduction of it on such kinds of land, has been suggested as disadvantageous from their being so much more adapted to the raising of other kinds of crops.

The cone, bearded, or rivet sorts of such wheat are the most proper for the heavier, more moist, and less broken down and reduced kinds of land that have been more lately put in cultivation, on which very weighty crops are not unfrequently produced.

All these sorts of wheat are grown to the most advantage

and with the greatest success, where the bottom in the land is somewhat inclined to be firm and close.

In regard to the spring sort of this grain, it would seem to be capable of being cultivated on the strong and heavy, as well as on the lighter sorts of land; but that it is the most calculated for the latter, where the vegetation and growth are rapid, particularly such fenny lands as have a firm turf-earthly bottom. In these it rises in a very quick manner, and they are not by any means well suited for the winter sorts of wheat from their lightness, rendering them liable to be thrown out in that season.

Preparation of the Land.—Wheat is a crop that is usually grown after the land has been prepared by repeated ploughing and harrowing or summer fallowing; but which is often capable of being raised after different kinds of green crops, as well as those of the root and other sorts with equal or more advantage. In some cases, flax and hemp also afford a good preparation for this grain; but some consider beans as the most favourable preparation: and experiment has shewn tares, and clover, to be nearly equal to them in this intention. In the county of Norfolk, wheat almost constantly succeeds clover, except where pea or bean crops are interposed, the land being scarcely ever fallowed with this view, except in the instances of what are termed *bastard summer tills*. It has indeed been well observed, that if there is one practice in husbandry proved by modern improvement to be worse than another, it is that of sowing wheat on fallows; it is therefore only stated on this point, that in some counties the fallows are ploughed just before harvest on to two-bout ridges ready to plough and sow under the furrow in the spraining method, a seedman to every plough which reverses the ridges. In others they lay their lands into ten or twelve furrow-stitches or ridges, and sow some under the furrow, some under the harrow. That the ridges vary exceedingly, according to their wetness; and that in Kent they have by means of the turn-wrest plough, no lands at all, but a whole field, one even surface. It would be useless to expatiate on the circumstances of fallow-wheat which ought no where to be found. If fallows be or are thought necessary, let them be sown for barley or oats, or with any thing but wheat. However, in whatever manner or after whatever kind of crop this sort of grain may be cultivated, the soil should constantly undergo that sort of preparation that may be sufficient, according to the particular circumstances of the land, to bring it into a state of considerable fineness of mould, especially in the more superficial parts, and thereby prevent as much as possible the rising of weeds; for it has been well noticed by a late writer, that whoever has attended to the progress of this sort of crop, in such lands as have been well broken down and reduced, and in such as have been left in a lumpy crude state at the time of sowing, will have found the difference to be very considerable. But it may be noticed, that when this kind of crop is taken after clover, the land seldom undergoes more than one ploughing, which is mostly given immediately before the seed is sown. However, as the grassy matter, in many cases where this mode is adopted, is extremely apt to rise and injure the crops in the more early stages of their growth, it may be better to follow the practice adopted in some districts of using a skim-coultured plough, as by this contrivance the remains of the clover weeds, and grassy material on the surface, may be cut or skimmed off, and turned into the bottom of the furrows, where they are immediately covered with the loose mould from below to such a depth, that little or no inconvenience can be sustained by them, while the land is thus rendered more clean, and capable of being harrowed in a more perfect manner than where the common plough only is employed.

ployed. Besides, perhaps, a better bed of mould is turned up in this way for the seed to vegetate in, provided the furrow is not made of too great a depth and breadth, and remain some time before it is sown; which should constantly be attended to by the agriculturist in preparing this sort of ground for wheat-crops. But it is the custom of some counties, as of Norfolk and Warwick, where the land is often continued for nearly two years in a state of clover, to break them up in the latter end of June; in the second, giving two, and sometimes three ploughings. Where the situation is favourable, and the weather turns out suitable for reducing the soil to a proper state of tilth, this may be an advantageous practice, as by such means great benefit may be obtained by cutting the grass in the beginning of the season, in which it is to be ploughed up; but where circumstances of so favourable a nature do not occur, such a method of preparation must be less beneficial than that of giving only one ploughing. In the preparation of a clover ley for wheat, Mr. Duckett has noticed a singular experiment and practice. He had a field in which wheat rarely escaped being greatly root-fallen; not to lose sowing it with that grain, and at the same time to guard against the experienced malady, he scarified it repeatedly, till he had torn up the clover, and also produced tilth enough for drilling it in; then he collected the clover fragments, and carted them into the farm-yard to make dung, and drilled the field; the wheat having a firm bottom in an unstirred soil, escaped the disease, and yielded an ample produce. The clover bulb, which would have secured the dreaded looseness of soil, had it been turned down, made a large quantity of dung, and therefore was not lost to the farm, though the particular field was deprived of it. And it has been stated on the authority of a cultivator of much experience, that in cases where the clover-crops have been such as to leave the land in a foul condition in respect to weeds, it would be highly improper to sow them with this sort of grain, as from its remaining for such a great length of time upon the ground they may be liable to have their seeds perfectly evolved, and brought into a state of vegetation. In such cases, it has been suggested as more advantageous to have recourse to such sort of crops as may require the operation of hoeing during the time they are upon the ground. The putting in of wheat after pea-crops, is a practice that may probably be pursued with the most propriety and success in those districts that are, from the nature of their situation, sufficiently early to admit of the land being fully cleaned and prepared by repeated ploughings and harrowings, after such crops have been removed, before the proper time of sowing such grain. But where they are so late as only to allow of the land being prepared by one ploughing before the period of sowing, it is supposed by some to be an extremely hazardous practice to attempt the culture of wheat after such crops; as unless the ground be in a high state of tilth, there is little chance of a good crop being produced. This is the opinion of the writer of the work on modern agriculture; but the Norfolk farmers are in the constant habit of setting or sowing in wheat upon a pea-stubble with a single ploughing, and consider it a very safe and excellent husbandry. The pea-crop ought, however, to have been kept clean; and after it is harvested, the haulm harrowed off. They never plough a bean-stubble there more than once. In some counties, it is the constant practice to cultivate beans and wheat alternately on the same land for some time. This is the case on the stronger kinds of soil in the county of Kent, on which it is found to answer in a very advantageous manner; and where wheat is only occasionally sown after such crops, it is often found an useful practice; but in all such cases the beans should be

cultivated in drills at from twenty to thirty inches distance, in order that they may admit of being hand and horse hoed in the most perfect manner. If this method has been followed, and the business of hoeing during the growth of the crops effectually performed, the land may be sufficiently prepared for the succeeding wheat-crops by one ploughing, as the soil from being thus kept clean, and in high tilth, can scarcely fail of affording a good produce. It has been remarked, that where the farmer has a bean-stubble intended to be sown with wheat, he should give it the due tillage as early as possible, which should be regulated by the soil, as on some it may be better to trust the skim scufflers and scarifiers than the plough. That where the land is very clean, the great skim of the Isle of Thanet is capable of cutting through every thing, and loosening the surface sufficiently to enable the harrows to render it as fine as possible, being picked and burned by women. Where not so clean, the Kentish broodshare may be more effective. In other cases, the scuffler may be sufficient for the purpose. It is noticed that in this case, when the farmer has got the surface to his mind, he is to consider whether or not he should plough it, which is advisable if the soil be of a firm solid tenacious quality, and if he does not intend to drill the wheat: if he should plough such a soil he may not have any apprehension of root-fallen wheat, that is, failing roots, from a loose bottom; but he will bring up a new surface that may drill with difficulty, whereas that which has received the influences of the crop, atmosphere, and of his late operations, will be in exactly the right temper for the drill to work in. If the soil is of a more loose friable quality, and he should plough down the fine surface he has gained, he will give the wheat too loose a bottom, and he will run the chance of a root-fallen crop. In all such cases, or in any that have a tendency to this circumstance, he should determine not to plough at all, but drill directly; a method in which he saves tillage, and has the probability of a better produce.

This is rather a new practice on strong land, but such success has been seen in it as leaves no reason for doubting the soundness of its principles. It was done by Mr. Duckett on a sandy soil for years, and with great effect. It should be remembered, that whatever other circumstances may influence the growth of this grain, it loves a firm bottom to root in, and rarely flourishes to advantage where it is loose and crumbly; nor will a depth of such mould do, if the under stratum, in which it will attempt to fix its roots, be from its quality of a repellent nature. The best basis is the cultivable earth, firm from not having been lately disturbed. These observations, as being quite practical, are certainly deserving of the farmer's attention. Where the district is early, and the land is preserved in good order by proper modes of cropping, wheat may be grown after beans, whether cultivated in the drill or broad-cast system, with success, as there may be sufficient time to give the necessary preparation before the time of sowing, which cannot be done where they are late, and there is only time for one ploughing. But in other situations it is found advantageous when this crop is to be grown after either peas, beans, or tares, to plough the land in as light or shallow a manner as possible, and then harrow and take out the roots and weeds, so that they may be consumed on the ground in heaps; the field being after this formed into proper ridges for the reception of the seed by ploughing again a few inches deeper than the first. And in some cases, it is even harrowed after the second ploughing, and ploughed a third time for the putting in of the grain.

Wheat, too, may sometimes be cultivated after turnip-crops to advantage on the heavier turnip-soils, particularly

where they have been kept clean from weeds by repeated hoeings, and fed off upon the land at such early periods as to admit of the ground being prepared by once ploughing, in a light manner. In cases where this kind of crop is intended to be cultivated after potatoes, which, from their having a great tendency to lighten the soil as well as to exhaust it, should never be done on the lighter sorts of land in backward situations, or under any circumstances where a sufficient proportion of manure has not been applied for the potatoe-crops, one light ploughing immediately before the seed may be in most cases an adequate preparation; as where proper attention has been bestowed in the culture of such crops, the soil is generally left in a sufficiently fine condition for the purpose. It has been remarked, that the cause of wheat not succeeding well after potatoe-crops, in many instances, is, that, besides the land being rendered too light and porous by the growth and cultivation that are requisite for them, the wheat is more exposed to the injurious attacks of the grub, earth-worm, and other insects; and in some exposed situations, from the seed-time being too long protracted, the practice becomes obviously improper. In growing the crop after those of hemp and flax, as weeds are apt to rise, it is always proper that the land should be ploughed over two or three times, in order that a fine state of tilth may be produced. The custom of giving but one earth after such sorts of crops, can seldom or ever ensure full returns of this grain. It has been remarked in "Practical Agriculture," on the best authority, that experience has shewn, in the most clear and satisfactory manner, that this sort of crop should never, when it can be avoided, be grown after other kinds of grain-crops, as rye, barley, or oats; and that the manure should not be applied to it, but for such crops as may precede it. That where the contrary is practised, the crop is not only liable to be injured by the rampant growth of weeds, but from its being more apt to be diseased.

On the whole, it may be observed, that whatever the nature or state of the ground may be, or the kinds of crops that precede this sort of grain, it would appear that the preparation for it should always be such as has a tendency to reduce the parts of the soil to a pretty fine state, as under such circumstances the growth of the crops is not only more regular and perfect, but from the even and compact state in which the surface is left, it is more fit for affording support and protection to the roots of the wheat-plants, as allowing them to spread and extend themselves with greater readiness in the fine mouldy earth thus provided, as well as by its falling down more closely about them. It has, however, been contended by some cultivators, that a rough cloddy state of the surface-part of the land is the most proper situation of it for the reception of this kind of crop, as the young wheat-plants are thereby better guarded and secured against the effects of the severe cold that often takes place in the winter season. It is probable, however, that cold is seldom hurtful, in any great degree, to winter wheat-crops, except when accompanied with too much moisture, or where sudden frosts and thaws have the effect of rendering the surface parts of the soil so light and open, as to be incapable of affording proper support to the roots of the young wheat-plants.

In Berkshire they prepare the land for wheat chiefly in three different ways, as by summer fallowing, and manuring with yard-dung, compost, rags, foot, and chalk in some cases; by folding on it with sheep in cases where the ground is not of too deep and wet a nature; and by putting it in on the back of clover-leys, after one or two crops of grafs by one or more ploughings.

It is thought by some, however, that manuring for beans or other crops is a much better practice when followed by wheat, than the old custom of fallowing and manuring for this crop, which renders the land too light, and consequently subject to blight.

The farmers in Oxfordshire prepare for wheat by different numbers of ploughings, as the circumstances of the land may be; but the layers are mostly ploughed in a shallow manner, as wheat loves a firm bottom to root in, and which, in sandy land, cannot be too tight. Too loose a bottom is apt to cause a root-fallen crop.

An equally careful preparation of the soil is necessary for the spring sort of this grain, though fewer ploughings will often be sufficient.

Time of sowing.—In regard to the proper period of sowing this sort of crop, it may, the author of Modern Husbandry observes, be useful to remark, that the earlier the autumnal sowings can be put into the soil, the greater chance the young plants will have of being well established before the frosts take place, which has been seen to be a circumstance on which the welfare of the crop in a great measure depends. Besides, the state of the land and that of the season are much more proper for the process of vegetation, when the crop is put in at an early period, than when it is delayed till a late one; the state of the weather in the latter case often admitting of only a very languid and imperfect growth till the spring, by which the crop must be exposed to much danger from various causes. Indeed experience has abundantly shewn that late sown wheats seldom succeed so well, or afford such plentiful crops as those that are put in early. But when sown too early there may notwithstanding be danger of the crop running too much to straw, and consequently of the grain proving light in the ear. From the beginning of September to the middle, or even the end of October, may probably be considered as the most favourable period for this business. This is indeed confirmed by the established practice of the most correct farmers in almost every district of the kingdom where this sort of grain is grown. If sown earlier, especially on the heavy kinds of soils, the land is for the most part in too hard and lumpy a state to allow of the seed being properly covered by the harrow; and in the lighter ones in too dry a condition for the grain to vegetate in a proper manner: and when delayed later, the ground in one case is apt to become too wet and close by the falling of the autumnal rains, and in the other too loose and porous from the action of the frost upon it. It is remarked by the writer just mentioned, that more than four-fifths of the whole of this sort of grain is sown between the middle of the first and the end of the last of the above months. Mr. Young thinks September the best season for cold backward wet soils, and October for those of the more dry and warm kinds, after there has been a plentiful rain. There are, however, circumstances, it is farther observed, on the authority of the Synopsis of Husbandry, that may render the times of sowing different from the above; as where the soils are of the rich fertile, loamy, chalky, or gravelly kinds, it may be better to defer it in many instances to a considerably later period; as when such warm sorts of land are cropped too early, they are apt, it is said, to push the plants forward in such a rapid manner, that they become weak and spindling in the early spring months, and at the same time the crops are more liable to be infested with weeds, on account of the season being then more favourable to their growth. But that the practice of putting in crops of this sort so late as the latter end of November and beginning of December, frequently depends on the crops that precede them not being capable, from the lateness of

of the situation, or other causes, of being taken off so early as that the land may be made for the wheat-crop in the proper time. This is often the case after peas, beans, tares, turnips, and other similar crops. In these cases, on the lighter sorts of soils, and where drill culture is employed, it may often be an advisable practice to sow in the spring, as by such a delay the ground may be brought into a more perfect state of preparation than could be the case in sowing it so late in the winter.

It is indeed remarked in the Corrected Report on Agriculture for Middlesex, that those persons who sow wheat in autumn lose the great advantage of a previous crop of turnips, both as to destroying the weeds and manuring the land; and that they create the labour of either hoeing, harrowing, or otherwise tampering with the weeds and young wheat in the following spring. That a wet seed-time sometimes renders it impossible for the farmer of a clayey soil to sow his usual quantity of wheat in autumn; this should not induce him to sow his grain when the land is too wet for the occasion, but rather let him wait till the first favourable opportunity in the months of February or March, by which time frost will have rendered the land mellow, and then he should sow the residue of his wheat; as the probability is great that wheat sown on a mellow soil, in a dry February, will be more productive than if it had been sown on the same land, in an adhesive state, during a wet November.

That autumnal-sown wheat precludes cultivation for one entire year, which, apart from all other circumstances, gives great encouragement to the growth of weeds; but that in order to appreciate the great mischief done by sowing wheat in that season, its connection with the usual course of crops must be taken into consideration. For instance, first, in the ancient, and still very common course of fallow, wheat, oats, there is seldom any ploughing from the sowing of the wheat until the sowing of the oats, which is one year and a half; secondly, in the course of wheat, clover, spring corn, or pulse, there are two years together in which the plough cannot possibly be put into the ground; thirdly, in the valuable course of turnips, barley, clover, and wheat, the plough is shut out of the ground for two years and a half. That these three cases include most of the arable land in Britain, and they demonstrate the prodigious encouragement which such courses give to the growth of weeds. On the contrary, wheat sown in the spring occupies the ground only half a year; and that when that is placed in a succession with winter tares and turnips every two years, the weeds have not time to grow in such a manner as to do any material injury. There is no period in such a course of more than six months in summer, or eight in the winter, free from the operation of the plough. This degree of tillage keeps the land free of weeds, and, in that manner, preserves it from being exhausted by them; and, by giving the green and root crops to sheep and other cattle, on the land, it becomes doubly manured every other year, which cannot fail to force the growth of the wheat as though it were growing in a hot-bed.

It certainly is not in every possible case advisable to refrain from sowing wheat in the autumn, in order to sow it in the spring. A dry seed-time is of so much importance to the occupiers of adhesive and fenny soils, that they should not let any such time pass without sowing their grain. In the case of a dry autumn, which is the same thing as a fine seed-time, the farmers should sow all such land as is then ready, and thereby ensure the important points of a good seed-bed for their grain, and against the danger of a wet spring. On the other hand, the more rain that falls in autumn, the better chance there is of having a dry spring; and consequently in every wet autumn the wheat-sowing

should be postponed until the spring. The proof of the success of one instance of this kind may enable farmers to judge what is capable of being effected, even in an unfavourable situation, by patience in wet seasons, and exertion in such as are dry. A large wheat-farmer, near Haddington, in Scotland, owing to a wet autumn, delayed sowing his wheat until after the 19th day of February, between that time and the middle of March, seeding one hundred and forty-five acres with wheat, principally the Essex white and Egyptian red. The harvest in this case was about ten days later than usual, and the crop yielded from twenty-four to forty Winchester bushels on the acre, which weighed nearly sixty-two pounds each. On examination, the wheat was found a first-rate sample.

Such a successful case of raising fine wheat from the seed sown in the spring may afford reason for putting it in at that season in many cases. Such a practice has never been known to fail, by the writer, when performed early, and on land in good heart. The advantages of the practice are said to be many, and very considerable.

When the sowing is to be done later than the above periods in the spring, the true summer wheat is always to be used.

The exact periods at which this sort of grain may be put into the ground in different cases with the greatest chance of success, under different circumstances of soil and climate, have not hitherto, however, so far as we know, been fully ascertained and shewn by any correct trials; but the above periods of autumn sowing are in very common use by the best farmers.

In the counties of Essex, Suffex, Hertford, Oxford, and many others, most of the best farmers are in favour of early sowing; but more to the east it is done somewhat later. In Berkshire they sow their light lands early, and those that are rich at a later period.

The spring sort of wheat may be sown from about the middle of March to the end of the following month, in most parts towards the south; but most probably the sooner it is put in after that period of the above month, as the state of the season will permit, the better it will be in the crop or produce.

Seed.—In respect to the proportion of seed that is necessary in different cases, it must depend upon and be regulated by a variety of different circumstances, but in general from two to three bushels, according to the state of the soil, the nature of the climate, and the period in which it is put into the ground, may be the most suitable proportion for soils of a medium state of fertility, under the broad-cast method of husbandry; but where the drill system of culture is practised, a considerable less quantity may be sufficient for the purpose. In the drilling and dibbling methods of sowing, however, which are unquestionably the best where they are performed with correctness, six pecks of seed are sufficient; in the latter mode two rows being put in on a flag, care being taken to have the land rolled after having been ploughed a fortnight or more, and the seed dibbled in to a sufficient depth, without scattering, covering it in by bush harrowing.

Where the lands have a known disposition to mildew, a larger proportion of seed should be given, whatever the time or season in which it is put in may be. Much less seed is also necessary in early than late sowings. It is remarked that on the rich soils of Gloucestershire, the quantity generally sown is about seven pecks, while in Yorkshire it is from eight to twelve. Where the lands are in a suitable state of tillage for receiving crops of this grain, ten pecks have been advised by a practical writer as the medium proportion; but

WHEAT.

but much larger quantities are frequently sown in the northern parts of the kingdom. It is obvious, however, that where such large proportions of seed are made use of, the plants must be liable to be drawn up too much, and the crops in consequence to become weak and imperfectly fed, as well as smaller in the size of the ears. There may be also disadvantages from making use of too small proportions of seed, from the ground not being properly covered with plants; but where care is taken in the after-culture of the crops, less danger is probably to be apprehended from this than the other extreme, as a great number of plants will be supplied by the tillering or shooting out of new stems from the joints about the surface, in consequence of the mould being laid up against them.

In Hertfordshire, in the broad-cast method, from two to three bushels are usually sown. But in the county of Norfolk they sow broad-cast, from two to two and a half bushels; and in the drilling and dibbling methods, from five to six or seven pecks.

In Essex they sow broad-cast about two and a half bushels; and in the drilling and dibbling modes, from seven to ten or more pecks.

In Suffex they sow a large quantity of seed, some four bushels on ley land, and three upon tilth; others three and a half: but when this crop succeeds peas, only three, if it be early, but if late, more. The medium quantity is about three.

In Berkshire commonly from two and a half to three in the broad-cast sowings of this crop.

And in Oxfordshire from two to two and a half, and sometimes three.

In the sowing of the spring sort of this grain, the quantity made use of is various. Some, for a full crop, sow fourteen pecks to the acre, but with grass-seeds only nine. Eight pecks have produced an abundant crop in some cases, on the same portion of land. Others advise two bushels to the acre; and say that the earlier it is sown the less seed will be required. Sometimes three bushels are sown upon the acre. However, from two and a half to three bushels on the acre may be considered as the most proper quantity. In the dibbling method, four pecks and a half have been found sufficient for an acre and a half.

The broad-cast practice of putting this sort of crop into the ground is the most common on the heavier kinds of wheat-lands, as those of the clayey and loamy sorts, the seed being harrowed well in by a rather light harrow. But in the lighter sorts of wheat-lands, the drilling method is often practised when they are clean, and sufficiently mellow and mouldy on the surface. Sometimes, too, the seed is put in partly by the plough, and partly by the harrow. In some districts it is ploughed in on the fallows, and harrowed in on clover. The clover-leys are also occasionally ploughed in some cases, and have the seed suffled in, and folded upon by sheep. See *SOWING, SEED, &c.* Also *UNDER-FURROW Sowing.*

Some farmers prefer a stale furrow for sowing wheat upon, while others are in favour of the contrary practice. A stale furrow is probably, however, the best in many cases. See *STALE-Furrow.*

Preparing feed-wheat for sowing is practised in many cases and places in different modes and manners. See *PICKLING, STEEPING, &c.* Also *WHEAT-Seed, Lining of.*

The depth of putting the seed in should not probably be more than from one to two or three inches.

In some parts of Oxfordshire the last is the usual depth,
VOL. XXXVIII.

and the farmers are generally friendly to depositing the seed to a shallow depth.

It is also the practice with many farmers in these different districts to change their feed-wheat frequently.

In the county of Suffex, an intelligent and spirited farmer has found by long and attentive experience that a change of feed-wheat is of essential importance to the cultivator, as that feed which has been repeatedly sown over the same ground at length degenerates, and the produce each succeeding year becomes inferior in quality; on which account, wheat that is apt to run to straw is sown on ley-land, and the Hertfordshire white sort on pea-stubbles.

In other districts the practice is thought by the best farmers to be always proper; and that the feed-wheat should be brought from a colder soil or sort of land than that on which it is to be sown. See *Change of SEED,* and *SEED.*

As soon as the seed has been put into the land, it should constantly be laid as dry as possible by the construction of proper drains and water-furrows, so as in all seasons to keep the water from stagnating upon it. See *WATER-Furrowing.*

It has been lately suggested as a beneficial practice to have the feed-wheat well trodden in at the time of sowing it by sheep, or still heavier stock, on heavy as well as light soils; as by this means the young plants are prevented from dying away in the winter, from the land lying too light and hollow. But more facts are wanting to establish the utility of this method of practice in different cases. See *TREADING Wheat in,* and *PLOUGH.*

Although under the present practice and management in the cultivation of wheat, the autumn or winter sort must always necessarily occupy a large extent of the heavier kinds of wheat-lands in this country, and be raised in the manner that has been directed above; yet in a number of cases the true spring sort may be cultivated, grown, and had recourse to with great advantage, success, and benefit. But in all such culture, the real summer sort must always be employed, for though the winter kind may be put into the ground with advantage in many cases so late as after the middle of February, as has been seen above, it is better to have this real sort for later spring sowing, as it possesses many properties highly necessary for the purpose. By some it has been supposed that it would interfere with winter wheat, and that it may be difficult to find proper courses for introducing it. However, this sort of wheat should principally be cultivated and grown on soils or lands, and in climates which are not well suited for winter wheat, or in cases where that sort is particularly liable to mildew. But though it may not be suited for universal application, it is most likely to succeed in the lighter, the fenny, and the softer sorts of soil, where the winter wheat is apt to be thrown out of the earth by frosty seasons. In such cases the courses might be turnips, or rape, according to the nature of the land, spring wheat, clover, and oats, or some such rotations, as in such, if after the clover or other grass, the land be pastured for one year, the oat-crops will be certain, and abundantly productive.

The preparation in some cases might be the rendering the land fine and clean by one or more ploughing and proper harrowing, and in others by ploughing and burning, and sowing cole and other feeds and crops, for being fed off by sheep, or in some other such ways.

In this manner large crops have been raised in many different instances, as thirty Winchester bushels, or more, on the acre, which were ripe and ready at the same time with the other spring-sown grain. It is a wheat which is said to

yield as much flour in any given quantity as other wheats, and which does not appear to be subject to any disease, nor to have any disadvantages attending the cultivation of it. It does not require more manure than barley or beans, nor does it exhaust the land more. It answers extremely well for laying down with clover, in which case the clover-seed should be sown and harrowed in with the last harrowing for the wheat, and the usual quantity of grass-seeds sown. It is to be preferred to all other sorts of corn for raising crops of grass-seeds; owing to the small quantity of leaf which it bears, and which is of short duration, as it fades and falls down almost as soon as it has attained its full size: more air is thus admitted to promote the growth of the clover, or other grass; and the admission of more air may also contribute to prevent the mildew with which this sort of wheat is so rarely affected.

There is a further advantage stated to arise in the cultivation of this sort of wheat in some cases, which is, that on various soils, and in some seasons, it often happens that the autumnal-sown crop of wheat may be seen to fail and to go off in patches, from the injury of the wire-worms, or other causes. Consequently, that in the beginning of April, by raking spring wheat into the vacant places, as also where the wheat-plants may appear weak and thin set, the uniformity of the crop may be restored, and the spring wheat be ready for the sickle quite as early as the autumnal sown. And that, although such a mixed crop would render its produce highly improper for seed; for the miller's use it would afford no objection.

The remarks that are given below are the result of much experience and practice in the cultivation of this sort of wheat. It is found that crops of this kind are ready to cut quite as early as the autumnal-sown wheat in similar soils and situations. That it is highly probable that the success of this sort of wheat on clover ley may be found to depend more on the coming season than autumnal-sown wheat; as if the following season should prove dry, the crop would be more hazardous in the former than in the latter. In a dry summer it would seem that this wheat would have a better chance upon land that has been longer upon tillage than upon clover ley. That turnip and rape fallows, where the soil is not too light, seem highly proper for spring wheat. That pea and bean fallows may also in many instances prove eligible for spring wheat; and especially after having been ploughed early in the autumn, and benefited by the winter's rains and frost. That when the spring wheat is harrowed in, at the last light harrowing, clover-seeds, &c. may be sown, the ground will mostly be well set, and the seeds prosper equal to any in other cases. That in the application of top-dressings for this sort of wheat, it may seem, that in a long-continued dry season, the most eligible way would be by applying them at the same time when the wheat is sown. Only once lightly harrowing after may suffice. But that, in a moist and continued rainy season, top-dressing would probably prove to act more powerfully by being sown upon the surface of the soil; because top-dressings are most particularly calculated to invigorate the coronal roots of the wheat-plants, and thereby to cause them to tiller well. And that, when top-dressings are sown on the surface of the soil, the best time of applying them, it may seem, would be when the wheat is grown to the height of three or four inches; because if laid on before the blades of the corn-crop afford a kind of shelter, the finer particles thereof are liable either to be exhaled by the sun, or blown away by high winds, which frequently occur at that season. Moist and showery weather, at that critical period, will always be

found of the highest importance; therefore, the farmer would do well by having due attention to the state of the weather when employed on this business. And that, as a crop of this sort of wheat is so much more valuable than any other kind of spring-sown corn, there are good grounds for supposing that top-dressings cannot any other way be more beneficially employed.

Trials with this sort of wheat in other unfavourable cases of poor wet cold land likewise shew that this sort of grain may be had recourse to with considerable success in different cases. That five quarters *per acre* have been had on rich good land in perfect cultivation of excellent wheat of this kind, when put into the soil so late as the 4th of May. It is evident, that this sort of wheat has a rapid growth, being equally forward at harvest with the autumn-sown crops. That on the whole it seems probable, from the success that has attended this kind of culture in the fen, in the southern and the more northern districts of the kingdom, that it may be advantageously introduced in many different situations and circumstances of arable land.

We have already considered the history, nature, qualities, and many other properties and circumstances in relation to this sort of grain. See *SPRING-Wheat*.

Culture while growing.—In the culture of wheat after it has been put into the soil, there may be some difference, according as it has been sown, according to the preparation of the land, or other circumstances. But in all cases it should be kept perfectly clean and free from weeds, either by the horse or hand hoe, as weeds not only injure the crop in its growth, but lessen the value of its sample when brought to the market. And besides, the stirring of the mould on the surface amongst the plants may frequently be useful in other ways, in addition to that of preventing the growth of seed-weeds; for as in the heavy kinds of soils that are most adapted to this grain, the more superficial parts are liable to become so hard and baked as not to be easily penetrated by the new-formed or coronal roots of the plants in the early spring months, especially when they are very dry, and have been preceded by much wet; loosening of the earth, by any means whatever, must of course be of great utility. This effect is generally shewn to have taken place by the appearance and progress of the crop, which becomes of an unhealthy yellow colour, and advances but little in its growth. In such cases it has been suggested that harrowing once or oftener in a place may be of much service in the early spring months. Where the crops are thin, and of feeble growth, this operation may produce beneficial effects, by affording a sort of earthing up to the weak plants, and thereby promote a more vigorous growth, at the same time that a number of new shoots are sent off from the joints thus covered, and the crop in consequence rendered more full and abundant; and where the grain is too thick upon the ground, it may also be of utility by drawing out and destroying many of the plants. It has likewise been suspected by Dr. Darwin, that many of the root-fibres, by being torn in the operation, may prevent the over luxuriance of the stem and leaves, and by that means promote the more early fructification of the grain.

It has been observed by a late writer, that the practice of scarifying the young drilled wheat-crops should constantly be performed in an effectual manner, and not later than March: but that some have not supposed it to be so very beneficial, from not performing it at the proper time. Mr. Cook has, it is said, contrived two implements for this use, a fixed harrow and scarifier; the former executing its work merely by common tines or teeth, having three rows, which,

WHEAT.

by varying its position diagonally, one, two, or three of them may be brought to act in the space of nine inches, without injury to the rows of wheat-plants. If two, they may, it is said, be drawn in a breadth of three inches; if three, in a space of four inches, and these spaces widened at pleasure, but still so as to keep quite clear of the rows of wheat; and that by loading the harrow, the teeth are forced to a proper depth. Further, that the scarifier has teeth of various breadths; but for working at this season, between nine and twelve-inch rows, the narrowest are to be preferred. By the action of these tools the surface mould is, it is remarked, loosened, and the air admitted, being performed to the depth of two inches with safety, and without mould being raised so as to cover or bury the plants, the earth being only loosened, and not displaced. By these contrivances much work can be accomplished in a very short time. This process is also useful against the attacks of the worms. They horse and hand hoe their wheat-crops repeatedly in Essex, and with great advantage, though very expensive.

But the drilled and dibbled crops, where this method is not employed, particularly in the latter mode, where only one row is placed on a flag, must be hand-hoed in the intervals, which should be done the first time in the beginning of the above month, and a second time towards the end of it, or a little later. Some likewise do it to the broad-cast wheats, but this has been supposed injurious by many. The business of thiffling the wheat-crops should also be carefully performed in May, or in the very early part of the following month, in all cases where it may be necessary. The practice of rolling should also be employed without either having recourse to the harrow, or after it has been used, being highly beneficial where the surface is cloddy, and the operation is executed when the ground possesses a medium degree of moisture, as well by forcing the roots of the wheat into the earth, as by causing the new stems to rise. And in thin light soils, when this sort of grain is cultivated upon them, much benefit may also be produced in this way, by the roots of the plants being prevented from being so easily loosened and thrown out of the ground. And the same practice is recommended as generally useful by some where clover or grass-seeds are sown with wheat-crops, as a means of rendering the vegetation more secure and perfect.

In Berkshire, wheat-crops by the best farmers are hoed every where, and sometimes hand-weeded, the former on strong soils often twice.

By good cultivators in some parts of Oxfordshire, too, all the wheat-crops are hand-hoed in February or March, and weeded afterwards.

And in Sussex, the practice most commonly adopted is to hand-hoe wheat in the spring, sometimes only once, but frequently twice, as the nature of the preceding crop may have been. By some, however, hand-hoeing wheat is disapproved of, they never hoe white corn, having given it up, from a conviction that the crops were never benefited by the practice; but, on the contrary, that mischief was always done by it. On which, it is observed, that should the practice sometimes be right, and sometimes wrong; or right on some soils, and wrong on others, these contrary facts may probably depend on the spring roots, which are said to strike into the air, and enter the ground at some small distance from the stem. If a hand-hoeing be given just before the appearance of those roots, it may, on a bounden surface, prepare for their easy entrance; but if given afterwards, it is probable the effect would be mischievous, would retard the progress of the plant, and force

it to do its work over again, perhaps at a worse season. If this be the case, the benefit which results from hitting the time exactly, may by no means equal the probability of mischief upon a scale of any extent; in which the right time can scarcely be taken for the whole of a crop. It has been heard declared, too, by excellent farmers, that if a person would pay for the hoeing of their wheat, they would not permit the operation, being convinced that it does more harm than good.

It has also been recommended, in such cases where the land is not in a sufficient state of fertility or preparation to bring the crops to perfection, to make use of top-dressings. Substances of both the solid and fluid kinds have been made use of for this purpose; the first consist chiefly of the dung of different sorts of birds, after being brought into a powdery state, bone-dust, foot, peat-ashes, and various saline matters. The latter are principally the drainings of dung-hills, and other similar liquid materials. The former should be thinly sown over the crops with as much evenness as possible, as early in the spring as horses can be admitted upon the land without injury; and if it can be done when the weather is inclined to be moist, it is the better; a roller may then be passed over the crop with advantage. Where the latter substances are made use of, care should always be taken that the plants be not injured by having too large a quantity applied to them. In this practice, the expense should be a primary consideration, and small trials first made where dungs are not to be used. The proper season for performing the business is the beginning of February. See MANURE, and TOP-DRESSING.

It has been suggested, too, that the method of transplanting wheat may be had recourse to in particular cases, with beneficial consequences, as where there are some parts of such crops too thickly set upon the ground, while others are too thin, irregular, or patchy; as by thinning and setting out the plants of such overabundant parts, among those that are deficient, much service may be done to each of them. The first will be rendered more capable of admitting the operation of the hoe, and thereby of supplying more abundant nourishment for the luxuriant vegetation of the plants, and the latter be supplied with the proper number of plants, which could not be accomplished in any other way. And it has been stated, that when raised in the garden, one acre would be capable of affording sets for an hundred, when planted, after being properly divided at the distance of nine inches from each other; and that as the business of transplanting is to be performed in the spring, it is supposed that crops of this grain may be raised in this manner on lands that possess a greater degree of moisture than is suited to the healthy growth of wheat in general. Besides, clean crops may be produced in this way with much greater certainty, as where the ground is ploughed over just before the plants are set out, the grain may rise much quicker from the plants than the weeds from their seeds, and the crop in this way overpower even noxious plants. Advantages of other kinds have been stated by different writers, as the result of this mode of raising wheat-crops. It is a practice, which, as well as that of dibbling, has been had recourse to with success, both in Norfolk and Essex.

The custom of feeding down wheat-crops, where too forward or luxuriant in the early spring months, by means of sheep, is a practice that has been contended to be beneficial in many cases. The good effects, in such instances, according to Dr. Darwin, are supposed to arise from the removal of the upright central stems, by which means different new lateral stems or root scions are sent off or brought

brought forward with more vigour, by the acquisition of a larger proportion of nutritious matter from the joints in consequence, that must otherwise have been exhausted in supporting the central stems. It is, however, a method which has been found by experience to be the most useful on such strong and fertile lands as are apt to produce a larger proportion of straw than can be properly supported. In which cases, advantage has been said to be derived by feeding off the blade at two or more successive times; but in effecting the business, great care is necessary to see that the whole is completed before the crop begins to spindle, otherwise more injury than good may be produced. And on the lighter and poor descriptions of soils, the practice must be employed with great caution, as on such lands the growth of the crops may be so retarded, as to become weak and spindly. Besides, on those lands where they are very light, and the crops thin, injury may frequently be done by many of the plants being pulled up, on account of the closeness of the bite of the sheep. They should, therefore, never be suffered to remain upon the crops when the weather is wet, and the surface of the ground much loosened, or after sudden frosts and thaws; as in such cases much harm may be done by the plants being pulled up and destroyed.

The treading of the animals may, however, be of great service in all the light sorts of wheat-land, and where the crops are thin; as by it the earth will not only be pressed more closely about the roots of the plants, but the stems in many instances so forced into the ground and covered up, that new shoots will be sent off laterally, and the crops be thus rendered more full on the land. But where the soils are very stiff and adhesive, the growth of the crops may be checked and retarded by the practice, and of course the shoots thus caused become weak, affording only small ears and light grain. Observations and experiments have convinced a writer in the Bath Papers, that wheat ought not to be fed down with sheep, unless it be very rank in January; and that such crops should only be fed as were sown early. And it has been suggested, that though this practice has much similarity to that employed in gardening, of stopping the growth of the main stems of some sorts of plants, as those of the cucumber and melon kinds, by rubbing off or cutting away the central buds, in order to expedite their fruiting; yet in wheat-crops, where the principal stems are eaten down, except when they are early, and of very luxuriant growth, the ears of the new shoots may not have time to perfect the seed, and of course become light and shrivelled in the grain, and the new stems from their weakness be more apt to fall down and be lodged. These are circumstances that have been frequently observed to occur by Mr. Tull, in the feeding down of wheat-crops by means of sheep. And that the same philosophical observer supposes, that in the culture of wheat-crops, the most beneficial method is that of promoting, as much as possible, the time of blossoming, while that of ripening is protracted, as it is for the farinaceous reservoir of nutriment, deposited in the cotyledon of the new seed, in order to support the growth of the *coraculum*, or fresh embryo, that the plant is cultivated; which farinaceous deposition is effected in the interval between the blossoming and ripening of the corn, either before the impregnation of the pericarp or seed-vessel, or afterwards; and the weight and plumpness of the rain are thus augmented.

The practice of feeding down young wheats by sheep may, therefore, be often hurtful, by retarding the period of blossoming, as well as by restricting the growth of the stems of the wheat-plants.

Sheep have likewise been employed on young wheat-crops in other views, as it has been remarked, that as the coronal parts of the roots of such crops are liable to be laid bare and exposed for some inches in length about the surface of the earth, during severe frosty winters, the turning in sheep upon them in such circumstances when the ground is moist, and keeping them in motion, may tend to press them into the loose soil, and in that way produce new roots, as well as afford covering and protection to such as have been denuded. And, it is added, that some farmers who contend that much advantage is derived from it, turn sheep upon the crops where danger is apprehended from worms, slugs, and other insects; in order that by keeping them constantly in motion, such animals may either be wholly destroyed, or so fixed in the surface mould as to cause their more gradual death. There is a very great variety of these animals, which are supposed injurious to wheat as well as other crops; and for the destruction of which, lime, foot, and other saline matters, have been had recourse to with supposed advantage. See GRUB, SOOT, &c.

Wheat-crops are supposed to be much injured from different sorts of vegetable diseases, as the *Blight*, *Blast*, *Mildew*, *Smut*, &c. &c. See these different heads.

In the Essex Report it is mentioned, that a disease which had not before been noticed or heard of, was met with at Copdock in that district, which is called the *purples*. The ears affected are perceived at once by their colour, a dirty brown mixed with green, as if part were ripe, with some chests quite green: they feel nearly, but not quite, like blighted or abortive ears, which are brown, while the ears in general of the crop are of a bright red or white; when rubbed in the hand, as if to get the grain, no wheat is found, but apparently the small grains of a flattened indented globular form, and of a darkish purple, greenish or dark hue. It has not the smallest resemblance in appearance or scent to smutty grains or bladders, and is certainly a distinct distemper. In many of these purpled ears are found some grains of good wheat. In order to discover if all the ears from the same root were affected on trial, in many instances they were found all similar from every root. It is very singular that no account that is recollected should have been given of such a strange malady, and so distinct from all others. Smutty ears were found in the same field, under all the common circumstances of that distemper. In Kent, it is said, this distemper is called *cockle-eared*.

It has likewise been noticed, that particular states of the weather have considerable influence on wheat-crops, at particular periods of their growth. As when the season is sufficiently dry, there is seldom much injury done to them during the winter months, however severe they may be in other respects, nor in those of the summer, provided the weather is not too moist about the time of blooming, as where that is the case the crops are mostly deficient in their produce.

And several sorts of weeds are injurious to wheat-crops, where they have been sown upon lands in an imperfect state of preparation, as *charlock* on the light calcareous soils; the *corn poppy*, on those of the chalky kind, as well as *cockle*, *white-darnel*, *puck-needle*, and *couch*: likewise *colt's-foot* on the rather heavy kinds of lands. See these different heads, and WEED and WEEDING.

This sort of crop is shewn to be ripe and ready for the reaper by its straw turning of a yellow colour, its ears beginning to bend in the neck and hang down, there being no greenness in the middle of them, and the grain becoming hard and plump. It is remarked, in the Essex Report on

Agriculture, that some do not like to cut wheat green, except it be the American white, which is brittle, and must be cut early, to prevent a loss of ears. It rarely lays. In Rochford hundred they do not cut till the wheat is ripe; but some few reap while it is yet green. It is, however, observed by a good farmer, that most rough chaff wheats, if they do not stand till fully ripe, will not thresh well.

It is stated, too, in the Norfolk Report on Agriculture, that Mr. Parmenter, miller at Aylesham, a considerable farmer also, and a very intelligent man, remarked that the farmers let their wheat stand too long before cutting. They are apt to have a notion, that when millers give this opinion, it is speaking for their own interest; but he cuts his own wheat before it is ripe, and would do so on the largest scale, if he was not a miller. The quality is far superior, and the corn just as good. And Mr. M. Hill prefers cutting green, and never yet commenced harvest but he wished he had begun three days sooner.

In the first of these Reports on Agriculture, a practice termed *fagging* is noticed as being for the first time met with. When the wheat-crops are very heavy, with broad luxuriant leaves, men with sickles move regularly through it, strike off many of them, for lightening the top, as a preventive against being beaten down by rain. It should be done carefully, or damage may ensue. See REAPING, HARVESTING of Grain, STACKING, and THRESHING.

Produce.—In respect to the quantity of wheat produced upon an acre, it must vary considerably, according to the circumstances of soil and preparation, as well as the state of the season; for it has been found that in some years the yield is under twenty, while in others it is upwards of thirty bushels the acre, the soil and culture being in every respect the same. And the average return of this crop throughout the whole of the kingdom, is probably not more than from three to three and a half quarters. And Mr. Donaldson has, indeed, stated it at not more than three quarters the acre. The greatest crop of wheat, of which the author of the Report on Agriculture for Middlesex has any account, is, it is observed, sixty-eight bushels *per* acre; the least about twelve. The medium between these extremes is forty, which, it is conceived, would be the average of land highly conditioned. But the average produce of Britain does not, it is imagined, exceed one-half of this quantity, and yet, it is thought, that wheat is as certain a crop as any that is cultivated. It is observed, that the yield of several years varies the proportion which wheat bears to the straw in a very great degree, but that the average is about twelve bushels of wheat to each load of straw, weighing eleven hundred weight two quarters and eight pounds. It has been asserted, and probably with truth, that the straw of autumnal-sown wheat is more harsh, and less agreeable to cattle, than the straw of that which is sown in the spring. The weight of wheat by the bushel differs very much in different cases; but in most strong land districts it is usually about sixty-two or three pounds to that quantity.

The yield of wheat is the greatest at the time of reaping, and becomes successively less and less the longer it is kept, so as ultimately, in many cases, to be a disadvantage to the farmer of not less than nearly one shilling in the bushel.

It may be noticed, that it is necessary, with the view of ascertaining the goodness of a sample of wheat, to determine by the eye whether the berry be perfectly fed or full, plump and bright, and whether there be any adulteration proceeding from sprouted grains, smut, or the seeds of weeds; and by the smell, whether there be any improper impregnation, and whether it has been too much heated in the mow or upon the kiln; and finally by the feel to

decide if the grain be sufficiently dry, as when much loaded with moisture, it is improper for the uses of the miller and baker. In cases where a sample handles coarse, rough, and does not slip readily in the hand, it may be concluded not to be in a condition either for grinding or laying up for keeping.

Wheat is usually sold by the farmers to the dealers for being made into flour; and, in some cases, as seed-wheat for other districts, which is very advantageous, as the price in that way is mostly higher. The dealers, who convert it into flour, dispose of that to the different consumers, and the refuse part, as the pollard, to other persons for the food of horses, sheep, hogs, and other animals.

WHEAT, *Brining of.* See BRINING.

WHEAT, *Brush,* that sort of wheat-crop which is grown after oats, barley, or any other such kinds of grain, on light soils of the sandy and other similar sorts.

Brush-wheat crops are common in many of the more northern parts of this country, but the practice of putting wheat-crops in, in this way, is by no means to be much recommended, as they seldom answer any great purpose.

WHEAT, *Buck.* See BUCK-WHEAT.

WHEAT, *Buck,* in Botany. See POLYGONUM *Fagopyrum.*

WHEAT, *Cow,* in Botany and Agriculture. See MELAMPYRUM, and COW-WHEAT.

WHEAT, *Crossing of,* the practice of putting into the soil in sowing two different sorts of this grain of good qualities, in order to raise a new variety of a still better kind. The practice of crossing in this manner has been found to answer perfectly, not only in this case, but in those of peas, apple-trees, &c. by Mr. Knight. In his trials, in years when almost the whole wheat-crops of the country were blighted, the varieties procured by crossing alone escaped, though raised on different sorts of land, and in very different situations and circumstances. See SEED, and VARIETIES.

WHEAT *Fallow,* that sort of complete naked fallow on which wheat is sown. See FALLOW, and FALLOWING.

WHEAT *Grass,* a sort of grass met with in land of some kinds. In the trials made on grasses at Woburn, the qualities of it stand as below.

	Oz.	Lbs.	Oz.
From a rich sandy loam, the produce at the time of flowering was on the acre	196020	=	12251 4
Weight of the grasses when dry	78408	=	4900 8
Weight lost by the produce of the same extent of ground in drying			7350 12
The produce of the same space of land in nutritive matter	7657	=	478 9
In the creeping rooted wheat-grasses, the produce from a light clayey loam, at the time of flowering, was on the acre	196020	=	12251 4
Weight of the grasses raised on the same space when dry	78408	=	4900 8
Weight lost by the produce of the acre in drying			7850 12
The same extent of land afforded in nutritive matter	612510	=	38213 10

Sixty-four drachms of the roots afforded of nutritive matter 5.3 dr. The proportional value of the roots is therefore to that of the grass, as 23 to 8.

WHEAT, *Grinding and converting of, into Flour, &c.,* the art and means of reducing it into this state, in which there are much nicety and difficulty in some cases, especially with the thinner-skinned sorts of this grain.

It is stated by the writer of the work on Agricultural Chemistry, that in this country the difficulty of grinding thin-skinned wheat is in some measure an objection; but that this difficulty is easily overcome by moistening the corn. And on the authority of John Jeffery, esq., the consul-general at Lisbon, the following observations on the subject are given, as transmitted by Sir Joseph Banks. In order to grind hard corn of this sort with the mill-stones used in this country, the wheat must be well screened, then sprinkled with water at the miller's discretion, and laid in heaps, being frequently turned and thoroughly mixed together, which will soften the hulk so as to make it separate from the flour in grinding, and, of course, give the flour a brighter colour; otherwise the stinty quality of the wheat, and the thinness of the skin, will prevent its separation, and will render the flour unfit for making into bread.

The writer has been informed by a miller of considerable experience, and who works his mills entirely with the stones from this country or Ireland, that he frequently prepares the hard Barbary corn of this kind by immersing it in water in close wicker baskets, and then spreading it thinly on a floor to dry; much depends on the judgment and skill of the miller in preparing the corn for the mill according to its relative quality. It is observed, however, that it is not from this previous process of wetting the corn that the weight in the flour of hard corn is increased; but from its natural quality it imbibes considerably more water in making it into bread. The mill-stones must not be cut too deep, but the furrows very fine, and picked in the usual way.

The mills should work with less velocity in grinding hard corn than with soft, and be set to work at first with soft corn, until the mill ceases to work well; then put on the hard corn. Hard wheat always sells at a higher price in the market than soft wheat, on an average of from ten to fifteen per cent.; as it produces more flour in proportion, and less bran than the soft corn.

Flour made from hard wheat is more esteemed than what is made from soft corn; and both sorts are applied to every purpose.

The flour of hard wheat is in general superior to that made from soft; and there is no difference in the process of making them into bread: but the flour from hard wheat will imbibe and retain more water in making into bread, and will consequently produce more weight of bread. It is the practice in Lisbon, and which it is thought would be advisable to adopt in this country, to make bread with flour of hard and soft wheat, which, by being mixed, will make the bread much better. As the most stinty wheats are capable of being readily and easily ground by these means, much advantage may arise from the mixing of the flour of the thin-skinned wheats with those of the thicker-skinned kinds in the forming of bread, as well as in preventing the objections to the cultivation and growth of the former, on account of their steely quality, and grinding hard and with inconvenience. By these means many of the well-harvested and well-kept wheats of this country will be found to be equal to those of any other, for most purposes to which the flour is usually put. See *SPRING-Wheat*, and *WHEAT*. Also *VEGETABLES*.

In the Middlesex Corrected Report on Agriculture, it is stated, that the best flour is mostly used by the pastry-cooks, and the makers of fine biscuits, and the inferior sorts in the making of bread. That these have often the worse kinds of damaged foreign wheats, and other materials, mixed with them in grinding them into flour. And that, if the bread consumed in the metropolis was prepared from the wheat of this country, unmixed with the leaner produce of other nations, the trial detailed below would shew with accuracy

the quantity of bread that could be made from a Winchester bushel of that grain.

One bushel of the wheat of this country, which weighed sixty-one pounds, was taken. It was then ground, and the meal weighed $60\frac{3}{4}$ lbs.; which, on being dressed, produced $46\frac{3}{4}$ lbs. of flour, of the sort called seconds, which alone is used for the making of bread throughout the greater part of this country; and of pollard and bran $12\frac{3}{4}$ lbs., which quantity was bolted, and it produced in sharps 3 lbs., which being sifted produced in good second flour $1\frac{1}{4}$ lb.

The whole quantity of bread-flour obtained from the	lbs.	
bushel of wheat, weighed	-	48
	lbs.	
Fine pollard	-	$4\frac{1}{4}$
Coarse pollard	-	4
Bran	-	$2\frac{3}{4}$
		11
The whole together	-	59
To which add the loss of weight in manufacturing		
the bushel of wheat	-	2
		61

The sack of marketable flour is by law obliged to weigh 240 lbs., which is exactly the produce of five bushels of such wheat; and the sack of flour is constantly supposed to make eighty quarter loaves of bread; and consequently sixteen of such loaves are made from each bushel of such wheat. It is admitted, however, that two or three loaves more than the above quantity can be made from the sack of flour, when it is the genuine produce of good wheat; that is, in the proportion of about sixteen and a half loaves from each bushel of sound grain, and, it may be presumed, sixteen from a bushel of medium corn. The expence of making the sack of flour into bread, and disposing of it, is about 8s.

WHEAT, Indian. See *MAIZE*.

WHEAT, Mildew in. See *MILDEW*.

WHEAT, Must of, is, according to the ingenious Mr. Hatchett, a taint produced by damp upon the alyaceous part of the grain, or starch; and he conceives, that this taint is, in most cases, superficial. He proposes the following as a successful method of removing it.

The wheat must be put into a vessel capable of holding at least three times the quantity, and the vessel filled with boiling water; and the grain should then be occasionally stirred, and the hollow decayed grains, which float, may be removed. When the water has become cold, or in about half an hour, it is drawn off. Then rinse the corn with cold water, and having completely drained it, spread it thinly on the floor of a kiln, and thus thoroughly dry it, stirring and turning it frequently during this part of the process. Phil. Trans. for 1817, part i.

WHEAT Rickstand. See *STADDLE*, and *STAND*.

WHEAT, Root-fallen or Welten, that sort of wheat-crop in which the roots are thrown out of the ground by its lightness or porosity, as caused by frosts or other means. See *WHEAT*, and *WELT-Root*.

WHEAT, Rust in. See *RUST*.

WHEAT-Seed, Liming of, the practice of drying moistened corn of this sort by means of powdery lime. It is the custom in some places to make it wet over-night, with salt or other water, and to dust it over with the lime the next morning before it is sown, mixing it well together in the operation. By the lime, however, thus remaining so short a time on the grain before sowing, it has no time to penetrate into

into the corn; whereas, by moistening the wheat, and leaving it until the succeeding morning well limed, the lime has a greater power, it is supposed, in destroying the smut-powder, than when it remains on it only for half an hour, and is then mostly rubbed off the corn. Half a bushel of the strongest lime is sufficient for a quarter of wheat, when sifted over and mixed well with it.

In this last mode of drying seed-wheat with lime, it is found to be very efficient in preventing the crops from being diseased in some districts. See *STEERING Seed*.

As there is an uncertainty whether the effect in this practice is to be ascribed to the washing of the grain or the lime, some merely moisten the corn for the purpose of making the lime adhere to it; while others are extremely attentive to the liquor made use of and the washing of the seed, and simply make use of the lime for drying it for sowing. Lime is, however, considered as a great preventative of disease in the grain by many. It should always be used while fresh and newly slacked.

WHEAT, Setting of, the practice of putting it into the soil by the hand. In many parts of the vale of the county of Gloucester, they set wheat by the hand and line; but the difficulty of getting on with the work at the proper season, when on a large scale, in consequence of the want of hands, operates against the more general introduction of this practice. When wheat is set by the hand in this way, not more than three pecks of seed are made use of. On clover-leys wheat is often put in by the hand in small channels made across the beds, which have been formed by the plough to the width of half a ley, dropping the seed into them, and leaving a distance of about seven inches between the different channels. This mode is said to be good for late work; and the expence to be about seven shillings the acre, the seed being usually about six pecks. In some other districts the setting of wheat is said to be practised with much success and advantage; but it is probably too tedious and expensive a mode to be had recourse to on any large extent of wheat cultivation. See *DIBBLING*, and *SETTING of Wheat*.

WHEAT, Spring. See *SPRING-Wheat*, and *WHEAT*.

WHEAT, Smyrna, a peculiar kind of wheat that has an extremely large ear, with many lesser or collateral ears coming all round the bottom of the great one.

As this is the largest of all sorts of wheat, so it will dispense with the nourishment of a garden, without being overfed, and requires more nourishment than common husbandry in the large way can give it. In the common way its ears grow not much larger than those of our common wheat.

This sort of wheat seems, of all others, the most proper for the new method of horse-hoeing husbandry, as that method seems capable of giving as much nourishment as the farmer pleases, by often repeating the hoeing. Next to this, the white-cone wheat is best for this sort of husbandry; then the grey-cone wheat.

WHEAT-Stubble, Cutting and Collecting of, the useful practice of mowing and raking together the strong stubbles of wheat-crops, and stacking them up in or near the farm-yards as additional litter, and for other purposes. It should always be done as soon as possible after the wheat has been taken from the fields. See *STUBBLE*.

WHEAT, Tilling of, the throwing out of new shoots, stems, or stalks, from about the roots, so as to increase the thickness of the crops on the grounds. It takes place much more extensively in the autumnal and winter sown wheats than those of the spring sowings. See *TILLER*, and *WHEAT*.

WHEAT, Transplantation of, the practice of putting into the ground the young plants of wheat that have been raised in other places, or which stand too thick on the land. It is

observed in the Middlesex Report on Agriculture, that it is well calculated for increasing the quantity of corn produced from a single grain, and that it may be resorted to for the sake of curiosity when the cultivator has procured a small quantity of some new and very valuable variety of seed; but that a farmer should never extend it to his field culture.

There would be much loss in labour and in other ways, it is supposed, by this practice, and nothing be gained by it. See *TRANSPLANTING*, and *WHEAT*.

WHEAT, White-cone, a term used by our husbandmen, to express a peculiar kind of wheat, which is very strong, and has a large ear.

It is the best kind for sowing in fields subject to the blight; for the stalks of it being, for the most part, solid or full of pith, like a rush, not hollow, like those of common wheat; the insects that cause the blight, seizing on the stalks of other wheat, do this no injury, even though they should attack it; the stalks of this kind being often found full of the black specks, which are always the marks of that insect having been there, and yet the ear full, and the grain good.

This wheat makes very good bread, if the miller does not grind it too small, or the baker make his dough too hard, it requiring to be somewhat larger than other wheat-flour, and somewhat softer in the dough. A bushel of white-cone wheat will make considerably more bread than a bushel of Lammas wheat; but it gives it a somewhat yellowish cast.

WHEAT-Bird, in *Ornithology*, a name given by the people of Virginia to a species of bird, which, after the time of the sowing of the wheat in that country, made its appearance annually at the season of its beginning to ripen, and was never seen there before. See *MIGRATION of Birds*.

WHEAT-Ear, the English name of the common *ænanthe*, or *motacilla ænanthe* of Linnæus, called also the *white-tail* or *fallow-finch*. See *MOTACILLA Ænanthe*.

WHEATEN-BREAD. See *THEORY of Bread*, and *WHEAT, Grinding of, &c.*

WHEATFIELD; in *Geography*, a township of Pennsylvania, in the county of Indiana, with 1475 inhabitants.

WHEATLY, FRANCIS, in *Biography*, was born in London in 1747, and received his first instruction as an artist in Shipley's drawing-school. Whilst young he received several premiums from the Society for the Encouragement of Arts, &c. He does not appear to have had any particular instructor in painting, but by his own industry and ingenuity contrived to obtain some knowledge of it; and having formed an intimacy with Mr. Mortimer, whom he assisted in painting the ceiling at Brockett-hall, by that circumstance obtained considerable improvements. He had great employment in painting small whole-length portraits, to which he added landscape back-grounds with considerable taste. After practising some years in London, he went to Ireland, and was much employed in Dublin, where he painted a large picture of the Irish house of commons, with portraits of the most considerable political characters, by which he acquired great reputation. On his return to London he painted a picture of the soldiery attacking the rioters in 1780, which was well engraved by Heath.

About this time he appears to have changed his practice, and painted rural and domestic subjects in a manner which evidently exhibits them to have been the offspring of the natural bent of his mind. He was engaged in the Shakespeare Gallery, but failed to excite interest: neither his talent nor his style was suited to the character of the subjects given to him. In the slighter subjects of common life he was at home, and he touched them and composed them in a most agreeable manner, and with a very pleasing tone of colour:

colour: these he executed with rapidity, and, as he always fold them, he acquired sufficient money to indulge a natural propensity to the pleasures of the table. Hence he became a martyr to the gout, and died of that disease in 1801, at the age of 54. He was elected an academician in 1791.

WHEE, WHEY, *Whie*, or *Qui*, in *Rural Economy*, a term used to signify a young heifer, or heifer-calf, in different places and parts of the country.

WHEEANG, or WHANG, a provincial term made use of to signify a thong or strap of leather for the harness or gear of farm-teams, or other domestic purposes.

WHEEL, ROTA, in *Mechanics*, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on an axis.

For an account of the *wheel* and *axle*, as a mechanical power, see *AXIS* in *Peritrochio*, and *MECHANICAL Powers*.

The wheel is one of the principal mechanic powers. It has place in most engines: in effect, it is of an assemblage of wheels that most of our chief engines are composed. Witnesses clocks, mills, &c.

Its form is various, according to the motion it is to have, and the use it is to answer. By this it is distinguished into *simple* and *dented*.

WHEELS, *Simple*, are those whose circumference and axis are uniform, and which are used singly, and not combined. Such are the wheels of carriages, which are to have a double motion; the one circular about their axis; the other rectilinear, by which they advance along the road, &c. which two motions they appear to have; though, in effect, they have but one: it being impossible the same thing should move, or be agitated, two different ways at the same time.

This one is a spiral motion; as is easily seen, by fixing a piece of chalk on the face of a wheel, so as that it may draw a line on a wall, as the wheel moves. The line it here traces is a just spiral, and still the more curve, as the chalk is fixed nearer the axis.

The fact, however, has been disputed; and it has been alleged, that nothing is more easy than for any one, who will take the trouble to make the experiment, to prove its falsehood. Place the chalk on the face of the wheel, as directed, and you will find that, so far from its describing a just spiral, and that still the more curve as the chalk is fixed nearer the axis, the chalk, if placed on the periphery of the wheel, will describe a cycloid, and the nearer it is placed to the axis, the nearer will the line it describes approach to the straight line which is described by the axis itself. Moreover, it is not true, nor pretended to be so, that the same thing moves two ways at once in the rectilinear and circular motion of wheels. The local motion, or motion of the whole wheel, is rectilinear only; that of the parts of the wheel circular. Nor can this latter motion with any propriety be called that of the wheel, unless the same thing could also move quick and slow at the same time, which the different parts of the wheel, in revolving round its axis, evidently do. Jacob's *Obs.* on the *Structure and Draught* of *Wheel-Carriages*, 1773, p. 28, &c.

For a very nice phenomenon, in the motion of these wheels, see *ROTA Aristotelica*.

We shall add, that, in wheels of this kind, the height should always be proportioned to the stature of the animal that draws or moves them. The rule is, that the load and the axis of the wheels be of the same height with the power that moves them; otherwise the axis being higher than the beast, part of the load will lie upon him; or, if it be lower, he pulls to disadvantage, and must exert a greater force. Though *Stevinus*, *Dr. Wallis*, &c. shew, that, to draw a

vehicle, &c. over waste uneven places, it were best to fix the traces to the wheels somewhat lower than the horse's breast. See *WHEELS of Coaches*, &c.

The power of these wheels results from the differences of the radii of the axis, and circumference. The canon is this: "As the radius of the axis is to that of the circumference, so is any power to the weight it can sustain hereby."

This is also the rule in the axis in *peritrochio*; and, in effect, the wheel, and the axis in *peritrochio*, are the same thing; only, in theory, it is usually called by the latter name, and in practice by the former.

WHEELS, *Dented*, are those either whose circumference, or axis, is cut into teeth, by which they are capable of moving and acting on one another, and of being combined together.

The use of these is very conspicuous in clocks, jacks, &c.

The power of the dented wheel depends on the same principle as that of the simple one. It is only that to the simple axis in *peritrochio*, which a compound lever is to a simple lever.

Its doctrine is comprised in the following canon; *viz.* "The ratio of the power to the weight," in order for that to be equivalent to this, "must be compounded of the ratios of the diameter of the axis of the last wheel to the diameter of the first; and of the ratio of the number of revolutions of the last wheel, to those of the first, in the same time." But this doctrine will deserve a more particular explanation.

1. Then, if the weight be multiplied into the product of the radii of the axes, and that product be divided by the product of the radii of the wheels, the power required to sustain the weight will be found. Suppose, *e. gr.* the weight *A* (*Plate XL. fig. 83. Mechanics*,) = 6000 pounds, *BC* = 6 inches, *CD* = 34 inches, *EF* = 5 inches, *EG* = 35 inches, *HI* = 4 inches, *HK* = 27 inches: then will $BC \times EF \times HI = 120$; and $CD \times EG \times HK = 32130$. Hence the power required to sustain the weight, will be $6000 \times 120 \div 32130 = 22\frac{1}{2}$ very nearly; a small addition to which will raise it.

2. If the power be multiplied into the product of the radii of the wheels, and the factum be divided by the product of the radii of the axes; the quotient will be the weight which the power is able to sustain. Thus, if the power be $22\frac{1}{2}$ pounds; the weight will be 6000 pounds.

3. A power and weight being given, to find the number of wheels, and in each wheel the ratio of the radius of the axis, to the radius of the wheel; so as that the power, being applied perpendicularly to the periphery of the last wheel, may sustain the given weight.

Divide the weight by the power; resolve the quotient into the factors which produce it. Then will the number of factors be the number of wheels; and the radii of the axes will be to the radii of the wheels, as unity to the several wheels. Suppose, *e. gr.* a weight of 3000 pounds, and a power of 60, the quotient of the former by the latter is 50, which resolves into these factors, 4. 5. 5. 5. Four wheels are, therefore, to be made; in one of which, the radius of the axis is to the radius of the wheel, as 1 to 4; in the rest, as 1 to 5.

4. If a power move a weight by means of two wheels, the revolutions of the slower wheel are to those of the swifter, as the periphery of the swifter axis is to the periphery of the wheel that catches on it.

Hence, 1. The revolutions are as the radius of the axis *FE* to the radius of the wheel *DC*. 2. Since the number

ber of teeth in the axis F D, is to the number of teeth in the circumference of the wheel M, as the circumference of that to the circumference of this; the revolutions of the slower wheel M, are to the revolutions of the swifter N, as the number of teeth in the axis to the number of teeth in the wheel M, which it catches.

5. If the factum of the radii of the wheels G E, D C, be multiplied into the number of revolutions of the slowest wheel, M, and the product be divided by the factum of the radii of the axes which catch into them, G H, D E, &c. the quotient will be the number of revolutions of the swiftest wheel O. *E. gr.* If G E = 8, D C = 12, G H = 4, D E = 3, and the revolution of the wheel M be 1; the number of revolutions of the wheel O will be 8.

6. If a power move a weight by means of divers wheels, the space passed over by the weight, is to the space of the power, as the power to the weight. Hence, the greater the power, the quicker is the weight moved; and *vice versa*.

7. The spaces passed over by the weight and the power, are in a ratio compounded of the revolutions of the slowest wheel, to the revolution of the swiftest; and of the periphery of the axis of that, to the periphery of this. Hence, since the spaces of the weight and the power are reciprocally as the sustaining power is to the weight; the power that sustains a weight will be to the weight, in a ratio compounded of the revolutions of the slowest wheel, to those of the swiftest, and of the periphery of the axis of that, to the periphery of this.

8. The periphery of the axis of the slowest wheel, with the periphery of the swiftest wheel, being given; as also the ratio of the revolutions of the one, to those of the other; to find the space which the power is to pass over, while the weight goes any given length.

Multiply the periphery of the axis of the slowest wheel into the antecedent term of the ratio, and the periphery of the swiftest wheel into the consequent term; and to these two products, and the given space of the weight, find a fourth proportional: this will be the space of the power. Suppose, *e. gr.* the ratio of the revolutions of the slowest wheel, to those of the swiftest, to be as 2 to 7, and the space of the weight 30 feet; and let the periphery of the axis of the slowest wheel be to that of the swiftest, as 3 to 8: the space of the power will be found 280. For $2 \times 3 : 7 \times 8 :: 30 : 280$.

9. The ratio of the peripheries of the swiftest wheel, and of the axis of the slowest; together with the ratio of their revolutions, and the weight, being given: to find the power able to sustain it.

Multiply both the antecedents and the consequents, of the given ratios into each other, and to the product of the antecedents, the product of the consequents, and the given weight, find a fourth proportional: that will be the power required. Suppose, *e. gr.* the ratio of the peripheries 8 : 3; that of the revolutions 7 : 2, and the weight 2000; the power will be found 214 $\frac{2}{7}$. For $7 \times 8 : 2 \times 3 :: 2000 : 214\frac{2}{7}$. After the same manner may the weight be found; the power, and the ratio of the peripheries, &c. being given.

10. The revolutions the swiftest wheel is to perform while the slowest makes one revolution, being given; together with the space the weight is to be raised, and the periphery of the slowest wheel; to find the time that will be spent in raising it.

Say, As the periphery of the axis of the slowest wheel is to the given space of the weight; so is the given number of revolutions of the swiftest wheel to a fourth proportional:

which will be the number of revolutions performed while the weight reaches the given height. Then, by experiment, determine the number of revolutions the swiftest wheel performs in an hour; and, by this, divide the fourth proportional found before. The quotient will be the time spent in raising the weight. Wolf. Elem. Math. tom. ii. p. 214, &c.

WHEELS of a Clock, &c. are the crown wheel, contrate wheel, great wheel, second wheel, third wheel, striking wheel, detent wheel, &c. See CLOCK and WATCH.

WHEELS of Coaches, Waggon, &c. With respect to these, the following particulars are collected from the experiments and reasonings of Camus, Defaguliers, Beighton, Ferguson, Brewster, &c.

1. The use of wheels, in the draught of carriages, is two-fold; *viz.* that of diminishing, or of more easily overcoming the resistance arising from the friction of the carriage, and that of more readily surmounting obstacles, which form angular prominences on the plane over which they are drawn, and which must be either depressed by the weight of the carriage, or render it necessary for the carriage, with its load, to be lifted over them. They serve in their first use to transfer the friction from the under surface of the carriage, and the plane supporting it, to the surfaces of the axle and nave of the wheel. The common method of accounting for this advantage is by saying, that the resistance, arising from friction in planes of equal asperity, increases with the velocity of the motion; so that this velocity must be compared with that of the power necessary to move the machine, and overcome the friction; and it is obvious, at the same time, that the velocity of a circular motion diminishes gradually from the circumference to the centre. See FRICTION.

But to this position it has been objected, that the illustration is not applicable to the case: for, granting that, in the friction of sledges or flat surfaces, the resistance increases in proportion to the velocity of their motion, this is not a parallel case with that of a circular surface rolling over a flat plane. On the contrary, the velocity of motion, in the outer surface of a wheel, is greater than that of its nave, moving under the axle; while at such outer surface there is little or no friction at all; whereas at the nave, moving much slower, there is much more. Indeed, the friction, which the wheel would have against its supporting plane, if it did not turn round its axis, is by its turning round transferred almost wholly to the axis and nave; whose circular motion is notwithstanding so much slower. It is, indeed, notorious, that the great friction of the wheels of carriages lies between the axle and nave; and how then can it be properly asserted, that such friction is diminished at the axle, as the velocity of the circular motion is there diminished? Accordingly it has been alleged by a late writer, that friction is not diminished by the use of wheels, but merely transferred from the outer surface of the wheel to its nave and axle; and that in the case of a wheel rolling along the ground, the spokes act only as single levers, to overcome the friction of the periphery against the plane of its support, the prominences, constituting the roughness of the plane over which it moves, being the fulcra upon which they turn, and not the common centre of these spokes, as others have maintained, who say that the wheel acts, in overcoming friction, as an axis in peritrochio. However, in obviating the friction of the wheels in loaded carriages, their spokes act as double levers, resting on a fulcrum at each end. See the author's method of illustrating and evincing these principles, in Jacob's Obs. on Wheel-Carriages, p. 23, &c.

If carriages were to move along smooth horizontal planes,
Z z wheels

wheels would be useful only in overcoming friction; but as they are drawn along roads covered with loose stones, indented with cavities, they are farther useful in serving to depress, or raise the carriage over the one, and in raising it out of the other.

2. The wheels of all carriages ought to be exactly round; and the fellys should be at right angles to the naves, according to the inclination of the spokes, *i. e.* the plane of the curvature of the wheel should cut the nave at right angles, though it need not pass through the place where the spokes are inserted into the nave.

3. The spokes, according to Mr. Ferguson and most other writers on mechanics, should be inclined to the naves, so that the wheels may be dishing or concave. If, indeed, the wheels were always to go upon smooth and level ground, it would be best to make the spokes perpendicular to the naves, or at right angles with the axles; because they would then bear the weight of the load perpendicularly, which is the strongest way for the wood. But because the ground is generally uneven, one wheel often falls into a cavity or rut, when the other does not, and then it bears much more of the weight than the other does; in which case dishing wheels are best, because the spokes become perpendicular in the rut, and therefore have the greatest strength when the obliquity of the road throws most of its weight upon them; whilst those on the high ground have less weight to bear, and therefore need not be at their full strength. Besides, by this form of the wheels, the base of the carriage is extended, and it is thus prevented from being easily overturned, and the fellys are hindered from rubbing against the load or the sides of the cart. Dr. Brewster, however, is of opinion, that the disadvantages of concave wheels overbalance their advantages. Mr. Antice also, in his "Treatise on Wheel-Carriages," whilst he recommends concave wheels, candidly allows, that some disadvantages attend this construction of them; for the carriage thus takes up more room on the road, so that it is more unmanageable; and when it moves upon plane ground the spokes not only do not bear perpendicularly, by which means their strength is lessened, but the friction upon the nave and axle is made unequal, and so much the more as they are the more dished. Dr. Brewster farther shews, that they are more expensive, more injurious to the roads, more liable to be broken by accidents, and less durable in general, than those wheels in which the spokes are perpendicular to the naves. From these and other considerations, our author is decidedly of opinion, that if wheels are to be composed of naves, spokes, and fellys, the rim should be cylindrical, and the spokes perpendicular to the naves; whereas in concave wheels, the rims are uniformly made conical, which subjects them to a variety of disadvantages. Every cone that is put in motion upon a plane surface will revolve round its vertex, and if force is employed to confine it to a straight line, the smaller parts of the cone will be dragged along the ground, and the friction greatly increased. Now when a cart moves upon conical wheels, one part of the cone rolls while the other is dragged along, and though confined to a rectilinear direction by external force, their natural tendency to revolve round their vertex occasions a great and continued friction upon the linch-pin, the shoulder of the axle-tree, and the sides of deep ruts.

Dr. Brewster has made some farther observations on the construction of certain parts of the wheels. The iron plates, he says, of which the rims are composed, should never be less than three inches in breadth, as narrower rims sink deep into the ground, and therefore injure the roads and fatigue the horses. See the sequel of this article.

4. The axles of the wheels ought to be perfectly straight, and at right angles to the shafts, or to the pole. When the axles are straight, the rims of the wheels will be parallel to each other, and then they will move the easiest, because they will be at liberty to go on straight forwards. But in the usual way of practice, the axles are bent downwards at their ends; which brings the sides of the wheels next the ground nearer to one another than their higher sides are; and this not only makes the wheels to drag sideways as they go along, and gives the load a much greater power of crushing them than when they are parallel to each other, but also endangers the overturning of the carriage when any wheel falls into a hole or rut, or when the carriage goes on a road which has one side lower than the other, as along the side of a hill. Thus, in the hind view of a waggon or cart, let A E and B F (*Plate XL. fig. 9. Mechanics*) be the great wheels parallel to each other, on their straight axle K, and H C I the carriage loaded with heavy goods from C to G. Then as the carriage goes on in the oblique road A a B, the centre of gravity of the whole machine and load will be at C; and the line of direction C d D falling within the wheel B F, the carriage will not overset. But if the wheels be inclined to each other at the ground, as A E and B F are (*fig. 10.*), and the machine be loaded as before from C to G, the line of direction C d D falls without the wheel B F, and the whole machine tumbles over. When it is loaded with heavy goods which lie low, it may travel safely upon an oblique road, so long as the centre of gravity is at C (*fig. 9.*), and the line of direction C d D falls within the wheels; but if it be loaded high with lighter goods from C to L (*fig. 11.*), the centre of gravity is raised from C to K, which shews the line of direction K k without the lowest edge of the wheel B F, and then the load oversets the waggon. Mr. Beighton has offered several reasons to prove, that the axles of wheels ought not to be straight: for which we must refer to *Desaguliers' Exp. Phil. vol. ii. Appendix, p. 540, &c.* Moreover, if the axle were not at right angles to the pole or shaft, but this was on one side, then the coach or carriage would be drawn on one side, and almost all the weight would bear upon one horse. With some mechanics, it is a practice to bend the ends of the axle-trees forwards, and thus make the wheels wider behind than before. Mr. H. Beighton maintains, that wheels in this position are more favourable for turning; since, when the wheels are parallel, the outermost would press against the linch-pin, and the innermost would rub against the shoulder of the axle-tree. In rectilinear motions, however, these converging wheels occasion a great deal of friction, both on the axle and the ground, and must therefore be more disadvantageous than parallel ones. This fact is allowed by Mr. Beighton: but he seems to found his opinion upon this principle; that as the roads are seldom straight lines, the wheels should be more adapted to a curvilinear than to a rectilinear motion.

5. Large wheels are always more advantageous for rolling than small ones, in any case, or upon any ground whatever. If we consider wheels with regard to their friction upon the axles, it is evident, that small wheels must turn as much oftener round than the large ones, as their circumferences are less; and, therefore, a wheel which is twice as large as another will have twice the advantage in respect of the friction, the holes of the naves and axles, and the weights upon them, being equal. Again, if we consider the wheels as they sink into the earth, or fall into holes, the bearing of the great wheel being double that of the small one, it would sink but half so deep; and if the small wheel should meet with a hole of the same diameter with itself, it would wholly sink in, whilst only a segment less than half of the great wheel

WHEEL.

wheel would fall in: the same thing would also happen in marshy ground, where the small wheel would sink wholly in the same hole which the great one would sink into but in part. The large wheel would also have the advantage of a small one in rising over eminences or ruts that occurred; so that the former would go over ruts much higher than the latter; and indeed over any eminences, provided their height be not equal to its semidiameter. Desaguliers has reduced this matter to a mathematical calculation, in his *Exp. Phil.* vol. i. p. 171, &c.

A late writer has also proved, that a wheel of eight feet diameter has somewhat more than twice the advantage in overcoming obstacles of a wheel of two feet; and he found, in practice, that if it requires a certain power to draw a carriage of a certain weight over a certain obstacle, with wheels of any determinate diameter, it will require wheels of four times that diameter, to draw the same carriage over the same obstacle with half that power. This writer also observes, that, in the draught of carriages ascending inclined planes, the moving power acts not only against the vis inertiae, which is always equal to the absolute gravity of the load, but also against its relative gravity, which increases with the inclination of the plane; and with respect to carriages raised on wheels, it is to be observed, that the higher the axle is removed from the plane, the farther is the centre of gravity removed out of the perpendicular line of support; so that the lower the wheel, the less is the relative gravity of the carriage. Hence he infers, that supposing the friction of two carriages of equal weight, but of different sized wheels, to be equal, the low-wheeled one would be drawn up hill, on a smooth plane, much more easily than the high-wheeled one; though on a smooth, horizontal plane, the latter would be drawn more easily than the former. On the contrary, in going down hill, the high-wheeled carriage will be urged forward, by its relative gravity, more than the low-wheeled one. *Jacob, ubi supra, p. 63, &c.*

It appears, therefore, that the larger wheels are, the more advantageous they are in proportion, provided that they are not more than five or six feet in diameter; for when they exceed these dimensions, they become heavy; or if they are made light, their strength is proportionably diminished, and the spokes, being long, are more liable to break: besides, horses applied to such wheels, would be incapable of exerting their utmost strength, by having the axles higher than their breasts, so that they would draw downwards; as in small wheels the draught is made more difficult, by the horses drawing upwards.

It is observed by Dr. Brewster, in the appendix to his edition of "*Ferguson's Mechanics*," that when the wheels of carriages either move upon a level surface, or overcome obstacles which impede their progress, they act as mechanical powers, and may be reduced to levers of the first kind. In order to elucidate this remark, which is of great importance in the present discussion, let *A* be the centre, and *BCN* the circumference of a wheel 6 feet in diameter, and let the impelling power *P*, which is attached to the extremity of a rope *ADP*, passing over the pulley *D*, act in the horizontal direction *AD*. Then, if the wheel is not affected by friction, it will be put in motion upon the level surface *MB*, when the power *P* is infinitely small. For since the whole weight of the wheel rests on the ground at the point *B*, which is the fulcrum of the lever *AB*, the distance of the weight from the centre of motion will be nothing, and therefore the mechanical energy of the smallest power *P*, acting at the point *A*, with a length of lever *AB*, will be infinitely great when compared with the resistance of the

weight to be raised; and this will be the case, however small the lever *AB*, and however great be the weight of the wheel. But as the wheels of carriages are constantly meeting with impediments, let *C* be an obstacle six inches high, which the wheel is to surmount. Then the spoke *AC* will represent the lever, *C* its fulcrum, *AD* the direction of the power; and if the wheel weighs 100 pounds, we may represent it by a weight *W*, fixed to the wheel's centre *A*, or to the extremity of the lever *CA*, and acting in the perpendicular direction *AB*, in opposition to the power *P*. Now the mechanical energy of the weight *W* to pull the lever round its fulcrum in the direction *AE*, is represented by *CE*, while the mechanical energy of an equal weight *P* to pull it in the opposite direction *AF*, is represented by *CF*; an equilibrium, therefore, will be produced, if the power *P* is to the weight *W* as *CE* to *CF*, or as the sine is to the cosine of an angle, whose versed sine is equal to the height of the obstacle to be surmounted; for *EB*, the height of the mound *C*, is the versed sine of the angle *BAC*, and *CE* is the sine, and *CF* the cosine of the same angle. In the present case, where *EB* is six inches, and *AB* three feet, *EB*, the versed sine, will be 1666, &c. when *AB* is 1000; and, consequently, the angle *BAC* will be $33^{\circ} 33'$, and *CE* will be to *EF*, as 52 to 83, or as 66 to 100. A weight *P*, therefore, of 66 pounds, acting in a horizontal direction, will balance a wheel six feet diameter, and 100 pounds in weight, upon an obstacle six inches high; and a small additional power will enable it to surmount that obstacle. But if the direction, *AD*, of the power, be inclined to the horizon, so that the point *D* may rise towards *H*, the line *FC*, which represents the mechanical energy of *P*, will gradually increase, till *DA* has reached the position *HA*, perpendicular to *AC*, where its mechanical energy, which is now a maximum, is represented by *AC*, the radius of the wheel; and since *EC* is to *CA* as 53 to 1000, a little more than 53 pounds will be sufficient for enabling the wheel to overcome the obstacle.

Proceeding in this way, it will be found, says our author, that the power of wheels to surmount eminences increases with their diameter, and is directly proportional to it, when their weight remains the same, and when the direction of the power is perpendicular to the lever which acts against the obstacle. Hence we see the great advantages which are to be derived from large wheels, and the disadvantages which attend small ones. There are some circumstances, however, which confine us within certain limits in the use of large wheels. When the radius *AB* of the wheel is greater than *DM*, the height of the pulley, or of that part of the horse to which the rope or pole *DA* is attached, the direction of the power, or the line of traction *AD*, will be oblique to the horizon as *A d*, and the mechanical energy of the power will be only *A e*, whereas it was represented by *AE* when the line of traction was in the horizontal line *DA*. Whenever the radius of the wheel, therefore, exceeds four feet and a half, the height of that part of the horse to which the traces should be attached, the line of traction *AD* will incline to the horizon, and by declining from the perpendicular *AH*, its mechanical effort will be diminished; and since the load rests upon an inclined plane, the trams or poles of the cart will rub against the flanks of the horse, even in level roads, and still more severely in descending ground. Notwithstanding this diminution of force, however, arising from the unavoidable obliquity of the impelling power, wheels exceeding four and a half feet radius have still the advantage of smaller ones; but their power to overcome resistances does not increase so fast as before. Hitherto we have supposed the weight of the large and small wheels to be the same, but

it is evident that when we augment their diameter we add greatly to their weight; and by thus increasing the load, we sensibly diminish their power.

From these remarks, we see the superiority of great wheels to small ones, and the particular circumstances which suggest the propriety of making the wheels of carriages less than four feet and a half radius. But even this size is too great; and it may be safely asserted that they should never exceed six feet in diameter, nor ever be less than three feet and a half.

6. Carriages with four wheels, as waggons or coaches, are much more advantageous than carriages with two wheels, as carts and chaises; for in applying horses to a carriage with two wheels, it is plain that the tiller carries part of the weight, in whatsoever manner it be kept in equilibrio upon the axle. In going down a hill, the weight bears upon the horse; and in going up a hill, the weight falls the other way, and lifts the horse, by which means part of his force is lost. Besides, as the wheels sink into the holes in the road, sometimes on one side, sometimes on the other, the shafts strike against the tiller's flanks, which is the destruction of many horses. Add to this, that when one of the wheels sinks into a hole or rut, half the weight will fall that way, whereby the carriage will be in danger of being overturned.

7. It would be much more advantageous to make the four wheels of a coach or waggon large, and nearly of a height, than to make the fore-wheels of only half the diameter of the hind-wheels, as is usual in many places. The fore-wheels of carriages have commonly been made of a less size than the hind ones, both on account of turning short, and to avoid cutting the braces. Crane-necks have also been invented for turning yet shorter, and the fore-wheels have been lowered, so as to go quite under the bend of the crane-neck. See an account of an ingenious contrivance for this purpose, under PERCH.

Some carriers and coachmen have, indeed, absurdly alleged, that when the fore-wheels are much lower than the hind ones, they serve to push them on. However, many disadvantages attend this construction. A considerable force is lost that would be effectual, if they were large: the carriage would go much more easily, if the fore-wheels were as high as the hind-ones; and the higher the better, because their motion would be so much the slower on their axles, and consequently the friction proportionably diminished. The jolting and uneasy motion occasioned by low wheels, has induced persons to contrive springs, in order to prevent it. But nothing can be more inconsistent, even with this end, than the common method of fixing the braces to the bottom of the body of a carriage. In consequence of this practice, the centre of gravity of the suspended body is so high above the centre of its motion, that it is liable to be continually agitated by the jolting of the carriage, and its danger of overturning increased: whereas if, instead of practising this method, the body were suspended as near as possible to its centre of gravity, the agitation of the carriage, as well as its danger of overturning, would be in a great measure avoided.

The effect of the suspension of a carriage on springs is to equalize its motion, by causing every change to be more gradually communicated to it, by means of the flexibility of the springs, and by consuming a certain portion of every sudden impulse in generating a degree of rotatory motion. This rotatory motion depends on the oblique position of the straps suspending the carriage, which prevents its swinging in a parallel direction; such a vibration as would take place if the straps were parallel, would be too extensive, unless they were very short, and then the motion would be some-

what rougher. The obliquity of the straps tends also in some measure to retain the carriage in a horizontal position: for if they were parallel, both being vertical, the lower one would have to support the greater portion of the weight, at least according to the common mode of fixing them to the bottom of the carriage; the spring, therefore, being flexible, it would be still further depressed. But when the straps are oblique, the upper one assumes always the more vertical position, and consequently bears more of the load; for when a body of any kind is supported by two oblique forces, their horizontal thrusts must be equal, otherwise the body would move laterally; and in order that the horizontal portions of the forces may be equal, the more inclined to the horizon must be the greater: the upper spring will, therefore, be a little depressed, and the carriage will remain more nearly horizontal than if the springs were parallel. The reason for dividing the springs into separate plates has already been explained: the beam of the carriage, that unites the wheels, supplies the strength necessary for forming the communication between the axles: if the body of the carriage itself were to perform this office, the springs would require to be so strong that they could have little or no effect in equalizing the motion, and we should have a waggon instead of a coach. The ease with which a carriage moves, depends not only on the elasticity of the springs, but also on the small degree of stability of the equilibrium, of which we may judge in some measure, by tracing the path which the centre of gravity must describe, when the carriage swings.

There is an inconvenience which attends the usual method of loading carriages; for when a carriage is loaded equally heavy on both axles, the fore-axle must endure as much more friction, and consequently wear out as much sooner than the hind-axle, as the fore-wheels are less than the hind ones. However, the carriers commonly put the heavier part of the load upon the fore-axle of the waggons; which not only makes the friction greatest where it ought to be least, but also presseth the fore-wheels deeper into the ground than the hind-wheels, although the fore-wheels, being less than the hind ones, are with so much the greater difficulty drawn out of a hole, or over an obstacle, even supposing the weights on their axles were equal; for the difficulty, with equal weights, will be as the depth of the hole, or height of the obstacle, is to the semi-diameter of the wheel. Moreover, since a small wheel will often sink to the bottom of a hole, in which a great wheel will go but a very little way, the small wheels ought to be loaded with less weight than the great ones; and then the heavier part of the load would be less jolted upward and downward, and the horses tired so much the less, as their draught raised their load to less heights. When the waggon-road, indeed, is much up-hill, there may be danger in loading the hind-part much heavier than the fore-part; for then the weight would overhang the hind axle, especially if the load be high, and endanger tilting up the fore-wheels from the ground. In this case, the safest way would be to load it equally heavy on both axles; and then as much more of the weight would be thrown upon the hind axle than upon the fore one, as the ground rises from a level below the carriage. But as this seldom happens, a small temporary weight might be laid upon the pole between the horses, which would overbalance the danger.

From Mr. Ferguson's observations on the centre of gravity, it is evident, that if the axle-tree of a two-wheeled carriage passes through the centre of gravity of the load, the carriage will be in equilibrio in every position in which it can be placed with respect to the axle-tree; and

WHEEL.

in going up and down hill, the whole load will be sustained by the wheels, and will have no tendency either to press the horse to the ground, or to raise him from it. But if the centre of gravity is far above the axle-tree, as it must necessarily be according to the present construction of wheel-carriages, a great part of the load will be thrown on the back of the horses from the wheels, when going down a steep road, and thus tend to accelerate the motion of the carriage, which the animal is striving to prevent: while in ascending steep roads a part of the load will be thrown behind the wheels, and tend to raise the horse from the ground, when there is the greatest necessity for some weight on his back, to enable him to fix his feet on the earth, and overcome the great resistance which is occasioned by the steepness of the road. On the contrary, if the centre of gravity is below the axle, the horse will be pressed to the ground in going up-hill, and lifted from it when going down. In all these cases, therefore, where the centre of gravity is either in the axle-tree, or directly above or below it, the horse will bear no part of the load in level ground. In some situations, the animal will be lifted from the ground when there is the greatest necessity for his being pressed to it, and he will sometimes bear a great proportion of the load when he should rather be relieved from it.

The only way of remedying these evils, says Dr. Brewster, is to assign such a position to the centre of gravity, that the horse may bear some portion of the load when he must exert great force against it, that is, in level ground, and when he is ascending steep roads; for no animal can pull with its greatest effort, unless it is pressed to the ground. Now, this may in some measure be effected in the following manner:—Let *BCN* (Plate XL. fig. 12.) be the wheel of a cart, *A* *D* one of the shafts, *D* that part of it where the cart is suspended on the back of the horse, and *A* the axle-tree; then if the centre of gravity of the load is placed at *m*, a point equidistant from the two wheels, but below the line *DA*, and before the axle-tree, the horse will bear a certain weight on level ground, a greater weight when he is going up-hill, and has more occasion for it, and a less weight when he is going down-hill, and does not require to be pressed to the ground. All this will be evident from the figure, when we recollect that if the shaft *DA* is horizontal, the centre of gravity will press more upon the point of suspension *D* the nearer it comes to it; or the pressure upon *D*, or the horse's back, will be proportional to the distance of the centre of gravity from *A*. If *m* therefore be the centre of gravity, *bA* will represent its pressure upon *D*, when the shaft *DA* is horizontal. When the cart is ascending a steep road, *AH* will be the position of the shaft, the centre of gravity will be raised to *a*, and *aA* will be the pressure upon *D*. But if the cart is going down hill, *AC* will be the position of the shaft, the centre of gravity will be depressed to *n*, and *cA* will represent the pressure upon the horse's back. The weight sustained by the horse, therefore, is properly regulated by placing the centre of gravity at *m*. We have still, however, to determine the proper length of *ba* and *bm*, the distance of the centre of gravity from the axle, and from the horizontal line *DA*; but as these depend upon the nature and inclination of the roads, upon the length of the shaft *DA*, which varies with the size of the horse, on the magnitude of the load, and on other variable circumstances, it would be impossible to fix their value. If the load, along with the cart, weighs four hundred pounds, if the distance *DA* be eight feet, and if the horse should bear fifty pounds of the weight, then *bA* ought to be one foot, which being one-eighth of *DA*, will make the pressure upon *D* exactly fifty pounds. If the road slopes four inches in one foot,

b m must be four inches, or the angle *b A m* should be equal to the inclination of the road, for then the point *m* will rise to *a* when ascending such a road, and will press with its greatest force on the back of the horse.

When carts are not constructed in this manner, we may, in some degree, obtain the same end by judiciously disposing the load. Let us suppose that the centre of gravity is at *O* when the cart is loaded with homogeneous materials, such as sand, lime, &c. then if the load is to consist of heterogeneous substances, or bodies of different weight, we should place the heaviest at the bottom, and nearest the front, which will not only lower the point *O*, but will bring it forward, and nearer the proper position *m*. Part of the load, too, might be suspended below the fore-part of the carriage in dry weather, and the centre of gravity would approach still nearer the point *m*. When the point *m* is thus depressed, the weight on the horse is not only judiciously regulated, but the cart will be prevented from overturning, and in rugged roads the weight sustained by each wheel will be in a great degree equalized.

In loading four-wheeled carriages, great care should be taken not to throw much of the load upon the fore-wheels, as they would otherwise be forced deep into the ground, and require great force to pull them forward. In some modern carriages, this is very little attended to. The coachman's seat is sometimes enlarged so as to hold two persons, and all the baggage is generally placed in the front, directly above the wheels. By this means the greatest part of the load is upon the small wheels, and the draught becomes doubly severe for the poor animals, who must thus unnecessarily suffer for the ignorance and folly of man.

There is another great disadvantage attending small fore-wheels; *viz.* that as their axle is below the level of the horse's breasts, the horses not only have the loaded carriage to draw along, but also part of its weight to bear, which tires them sooner, and makes them grow much stiffer in their hams, than they would be if they drew on a level with the fore-axle; and for this reason, coach-horses soon become unfit for riding. So that on all accounts it is plain, that the fore-wheels of all carriages ought to be so high as to have their axles even with the breasts of the horses; which would not only give them a fair draught, but likewise cause the machine to be drawn by a less degree of power.

Mr. Beighton disputes the propriety of fixing the line of traction on a level with the breast of a horse, and says it is contrary to reason and experience. Horses, he says, have little or no power to draw, but what they have from their weight; otherwise they could take no hold of the ground, and then they must slip, and draw nothing. Common experience also teaches, that if a horse is to convey a certain weight, he ought, that he may draw the better, to have a proportional weight on his back or shoulders. Besides, when a horse draws hard, he bends forward, and brings his breast near the ground; and then, if the wheels are high, he is pulling the carriage against the ground. A horse tackled in a waggon will draw two or three ton, because the point or line of traction is below his breast, by reason of the wheels being low. And it is very common to see, when one horse is drawing a heavy load, his fore-feet will rise from the ground; and he will nearly stand on end; in which case it is usual to add a weight on his back, to keep his fore-part down, by a person mounting on him, which will enable him to draw that load, without which he before could not move. The great stress, or main business of drawing, says this ingenious writer, is to overcome obstacles; for on level plains the drawing is but little, and then the horse's back need be pressed but with a small weight. Most or all of these obstacles may be considered

considered as inclined planes. In order to draw the wheel $A B$ (*Plate XL. Mechanics, fig. 13.*) over the obstacle D , M. de Camus, agreeably to the principles above laid down, would have the horse draw in the line $H C$; whereas Mr. Beighton says, since the obstacle is D , and the tangent of the earth, or line of the floor, is at B , and the line to be moved in is $B D$, an inclined plane; the easiest position of drawing, to get the wheel over D , is to draw in the position of that inclined plane $B T$, or its parallel $C b$. As all the radii of a wheel are equal, the pulling at the centre is the same as a balance in equilibrio; viz. there is the same force at A as at B . But in the case of drawing in the horizontal line $H C$, when the obstacle is at D , the whole force which the horse has for drawing is by the short end of the brachium $= e D$, against the force or weight of the long end of the brachium $f D = e C$, which must be very disadvantageous; therefore, he says, the line of traction should be $b C$. *Defag. Exp. Phil. vol. ii. App. p. 542, &c.*

Whilst M. Camus maintained that the line of traction should be an horizontal line, or always parallel to the ground on which the carriage is moving, because the horse can exert his greatest strength in this direction, and because the line of draught, being perpendicular to the vertical spoke of the wheel, acts with the largest possible lever, M. Couplet, considering that the roads are never perfectly level, and that the wheels are constantly surmounting small eminences, even in the best roads, recommends the line of traction to be oblique to the horizon. It is, however, to M. Deparcieux (*Sur le Tirage des Chevaux, Mem. Acad. Roy., 1760.*), that we are principally indebted for just ideas on this subject. He has shewn in the most satisfactory manner that animals draw by their weight, and not by the force of their muscles. In four-footed animals, the hinder feet are the fulcrum of the lever by which their weight acts against the load; and when the animal pulls hard, it depresses its chest, and thus increases the lever of its weight, and diminishes the lever by which the load resists its effects. Thus in *Plate XL. Mechanics, fig. 12*, let P be the load, $D A$ the line of traction, and let us suppose $F C$ to be the hinder leg of the horse, $A F$ part of its body, A its chest or centre of gravity, and $C E$ the level road. Then $A F C$ will represent the crooked lever by which the horse acts, which is equivalent to the straight one $A C$. But when the horse's weight acts downwards at A , round C as a centre, so as to drag forward the rope $A D$, and raise the load P , $C E$ will represent the power of the lever in this position, or the lever of the horse's weight, and $C F$ the lever by which it is resisted by the load, or the lever of resistance. Now, if the horse lowers its centre of gravity A , which it always does when it pulls hard, it is evident that $C E$, the lever of its weight, will be increased, while $C F$, the lever of its resistance, will be diminished, for the line of traction $A D$ will approach nearer to $C E$. Hence we may see the great benefit which may be derived from large horses, for the lever $A C$ necessarily increases with their size, and their power is always proportioned to the length of this lever, their weight remaining the same. Large horses, therefore, and other animals, will draw more than small ones, even though they have less muscular force, and are unable to carry such a heavy burden. The force of the muscles tends only to make the horse carry continually forward his centre of gravity; or, in other words, the weight of the animal produces the draught, and the play and force of its muscles serve to continue it.

From these remarks, then, according to Dr. Brewster's statement, we may deduce the proper position of the

line of traction. When the line of traction is horizontal, as $A D$, the lever of resistance is $C F$; but if this line is oblique to the horizon, as $A d$, the lever of resistance is diminished to $C f$, while the lever of the horse's weight remains the same. Hence it appears, that inclined traces are much more advantageous than horizontal ones, as they uniformly diminish the resistance to be overcome. Deparcieux, however, has investigated experimentally the most favourable angle of inclination, and found, that when the angle $D A F$, made by the trace $A d$, and a horizontal line, is fourteen or fifteen degrees, the horses pulled with the greatest facility and force. This value of the angle of draught will require the height of the spring-tree bar, to which the traces are attached in four-wheeled carriages, to be one-half of the height of that part of the horse's breast to that with which the fore end of the traces is connected.

This height is about four feet six inches, and therefore the height of the spring-tree bar should be only two feet three inches, whereas it is generally three feet.

8. The utility of broad wheels, in amending and preserving the roads, has been so long and generally acknowledged, as to have occasioned several acts of the legislature to enforce their use. See TURNPIKE.

Several excellent and well-devised experiments have not long ago been instituted by Boulard and Margueron, which have satisfactorily evinced the distinguishing advantage of broad wheels. See a Memoir presented to the Academy of Lyons, in the *Journal de Physique*, tom. xix. p. 424.

Nevertheless, the proprietors and drivers of carriages seem to be convinced by experience, that a narrow-wheeled carriage is more easily and speedily drawn by the same number of horses than a broad-wheeled one of the same burthen. And though government allowed them to draw with more horses, and carry greater loads than usual, they were persuaded with difficulty to comply with the requisition of legislature; and methods have been used to evade it. Their principal objection has been, that as a broad wheel must touch the ground in many more points than a narrow wheel, the friction must of course be so much the greater; not considering, that if the whole weight of the waggon, and load in it, bears upon many points, each sustains a proportionable less degree of weight and friction than when it bears only upon a few points; so that what is wanting in one is made up in the other, and, therefore, will be just equal under equal degrees of weight, as appears by the following plain and easy experiment proposed by Mr. Ferguson.

Let one end of a piece of packthread be fastened to a brick, and the other end to a common scale for holding weights; then having laid the brick edgewise on a table, and letting the scale hang under the edge of the table, put as much weight into the scale as will just draw the brick along the table. Then taking the brick to its former place, lay it flat on the table, and leave it to be acted upon by the same weight in the scale as before, which will draw it along with the same ease as when it lay upon its edge. In the former case, the brick may be considered as a narrow wheel on the ground; and in the latter as a broad wheel. And since the brick is drawn along with equal ease, whether its broad side or narrow edge touches the table, it shews that a broad wheel might be drawn along the ground with the same ease as a narrow one, supposing them equally heavy, even though they should drag, and not roll as they go along. Besides, as narrow wheels are always sinking into the ground, especially when the heaviest part of the load lies upon them, they must be considered as constantly going up hill, even on level ground; and their edges must sustain much friction by rubbing

WHEEL.

rubbing against the sides of the ruts made by them. But both these inconveniences are avoided by broad wheels; which, instead of cutting and ploughing up the roads, roll them smooth, and harden them: though, after all, it must be confessed, that they will not do in stiff, clayey cros roads; because they would soon gather up as much clay as would be almost equal to the weight of an ordinary load; and also in passing along roads abounding with loose stones and other obstacles, which a narrow wheel may avoid passing over, and a broad one must surmount, the broad-wheel carriage will certainly be drawn less easily and less speedily than a narrow-wheeled one, though not on account of any additional friction arising from the pressure of the weight on a greater quantity of surface. Broad wheels are likewise more liable to an inequality of pressure between the axle and box than narrow ones, and consequently to a greater wear and tear.

Jacob's Obs. on the Structure and Draught of Wheel-Carriages, 1773, p. 81, &c. See on the subject of the preceding article, Defag. Ex. Phil. vol. i. p. 201, &c. Ferguson's Lect. p. 56, &c. 4to., and Appendix by Brewster. Martin's Phil. Brit. vol. i. p. 229, &c.

We shall here subjoin some additional remarks on wheels and axles for carriages. The essential qualities of wheels are strength and durability, and it is desirable that they should be as light as is consistent with strength: for quick travelling carriages lightness is very necessary.

Wheels to four-wheel carriages should be made as near of a height as the construction and appearance will admit; and if not required for heavy work, the lighter they are made the better. The fixtures from whence the draught is taken should be placed rather above the centre of the largest wheel, for advantage of draught.

The members of a wheel are of three descriptions; *viz.* the nave, or stock, which is the central piece; the spokes, or radii; and the fellies, or circumference. The nave or stock is made of elm, in which all the spokes are fixed, and in which the axletree-box, or wheel-box, is confined, to receive the axle-arms on which the wheel revolves. The spokes are straight timbers made of oak, firmly tenoned in the nave, in the direction of radials, to support the fellies, or wheel-rim. The fellies are made of ash, or beech, and form the rim of the wheel; the whole circumference is usually divided into short lengths, in the proportion of one length to every two spokes. When the fellies are fixed on the spokes, the iron band, or tire, which maintains the wear, is nailed on in lengths, and keeps the fellies together. The diameters of wheels regulate the number of spokes and fellies they are to contain: for the larger the circumference of the wheel is, the greater is the number of spokes required in proportion; for they should not in any wheel be more than fifteen inches distant on the fellies, or circumference.

The usual height or diameter of wheels for coaches and travelling carriages extends to five feet eight inches, and are divided into four proportions. Those which contain from eight to fourteen spokes, and only half that number of fellies, are called eights, tens, twelves, or fourteens, which are the number of spokes in such wheels, or of fellies in a pair of wheels. The height which regulates the number is, for an eight-spoke wheel, not to exceed three feet two inches; for a ten, four feet six inches; for a twelve, five feet four inches; for a fourteen, five feet eight inches.

These are the extreme heights for the different numbers of spokes to each wheel, which should be rather more than less, in particular for the fore-wheel of a four-wheel carriage, which receives more stress than the hind one; and the coachmaker's rule is, when the hind-wheels are of that height to

require fourteen spokes, the fore one, if under the necessary height before stated, should have twelve; never allowing the fore-wheels to have but two spokes less than what is needful for the hind ones.

There are three descriptions of wheels; *viz.* the straked, the hooped, and the patent rim: the differences of these are only in the rims.

The straked wheel is made with the fellies in separate lengths or pieces, which are joined together at the ends by dowels; that is, a round pin which enters part into one piece and part into the other, being closely fitted into holes made in each. The iron with which it is plated is called the strake, and is put on in pieces of the same length as the pieces of the fellies, and fastened by nails; the joints of the iron are made to fall over the middle of the pieces of wood so as to unite them firmly together. The hooped wheel is surrounded by a hoop of iron in one entire piece. The patent wheel is made with a hoop of wood in one entire piece, by boiling or softening the wood until it can be bent into a circle; this is surrounded by a hoop of iron in an entire piece, and fastened by nuts and rivets.

According to the usual method of constructing straked wheels, their peripheries are composed of a number of pieces or fellies joined together; but these are weak, and subject to several inconveniences. As the joints are the weakest parts of the wheel, they are most liable to yield inward; for which reason the wheelwrights leave them higher than the other parts of the rim, in consequence of which the wheel is not exactly round within the circle of the rim. Besides, the fellies being segments of a circle, sawed or hewn out of straight wood, they are on this account rendered so brittle, from the cross direction of the grain near the joints, that they are with difficulty kept together, even though almost twice the quantity of timber be employed that would otherwise be necessary. The strength of such a wheel depends on the thickness of the iron tire or rim that surrounds it, and hence the carriage is loaded with an useless weight, both of wood and iron. To obviate these inconveniences, Mr. Viny invented the process for bending timber into a circular form, practised for some time by Messrs. Jacob and Viny, and is now continued by others. In wheels made of timber thus bent, the rim consists either of a single piece of wood, or two fellies only, and is cased with a single hoop of iron. By this mode of construction, the grain of the wood is kept parallel throughout, so that the periphery of the wheel is every where equally strong; its thickness is considerably lessened, inasmuch that though little more than half the usual quantity of timber is employed, the wheel is of itself strong enough to sustain the common burthen laid on such wheels, without the assistance of iron tires, which are only applied to them as a safe-guard, to preserve the wood from the injuries to which it would otherwise be necessarily exposed from the roads; and hence a less quantity of iron is sufficient, and even that will be fairly worn out before it becomes useless. Besides, the wheel is rendered much lighter, and at the same time much stronger and more durable, than wheels constructed of detached pieces of wood and iron, in the usual manner. These patent wheels are very superior to the common sort, in their neat light appearance, and in the length of time they wear, as two sets of the former will wear as long as three of the latter: their preservation depends very much on the hoops that the wheels are rimmed with. Some persons still prefer the common sort of wheels, on account of their being more easily repaired than the hoop-wheel; but though the repairing of the latter is more difficult, they are much less subject to need it.

As the rims of wheels wear soonest at their edges, they should

should be made thinner in the middle, and fastened to the fellies with nails of such a kind, that their heads may not rise above the surface of the rim. The fellies on which the rims are fixed should, in carriages, be three inches and a quarter deep, and in waggons four inches. The naves should be thickest at the place where the spokes are inserted, and the holes in which the spokes are placed should not be bored quite through, as the greafe upon the axle-tree would insinuate itself between the spoke and the nave, and prevent that close adhesion which is necessary to the strength of the wheel.

The track in which the wheels of every carriage are to run is generally the same, except when intended for particular roads, where waggons and other heavy carriages are principally used, and leave very deep ruts, in which light carriages must likewise run, or be liable to accident, and are also sure to be heavy in draught. All four-wheel carriages should have the hind and fore wheels regulated to roll in the same track. The ordinary width of the wheels is four feet eight or ten inches; that of waggons or carts generally measure five feet two inches; chaise-wheels, as being principally intended for the country, are adapted to this width. It is immaterial to what width wheels are set if used for running upon stones; but on marshy roads, if their exactness is not attended to, the draught is considerably increased. We have seen a carriage of which the iron axle-tree is made in two pieces, overlapping each other in the middle where they are joined, and secured by proper bands to the wood-work of the carriage, so as to admit of sliding in the direction of the axle-tree. These parts are cut with teeth like racks, and a pinion is applied between them; so that by turning this pinion round, the two parts of the axle-tree are made to slide one upon the other; and the wheels which are fitted upon the two extreme ends of the axle-tree can at pleasure be fixed at greater or less distance, as the roads require.

The different heights of hind and fore wheels make also a difference in the length of their axle-trees, agreeable to the proportion they bear to one another; the fore-wheel has the longest axle-tree by one or two inches between the shoulders.

The nave of the wheel is pierced through the centre, with a large hole to introduce the box, or iron tube, for the axle-arm, as this tends to weaken the wood. It has been frequently proposed to make metal naves, or centre-pieces for wheels, which should contain the box for the axis, and the mortises for the spokes of the wheel all cast of one piece of metal. Messrs. Dodson and Skidmore had a patent for this in 1799. The objection to it is, that, if the wood of the spokes shrinks, they become loose in the mortises, whereas a wooden nave shrinks at the same time with the spoke. This defect has been since remedied by making the metal wheel-stock in two parts; one with recesses, or sockets, to contain the spokes, and the other a flat plate to fasten against the former with screw-bolts, and press the spokes into their cavities. Mr. Plucknet had a patent for a metal wheel-stock of this kind in 1805, which answered extremely well for carts, waggons, and artillery. The spokes were made to fill up all the space in the nave or stock, so that each spoke touched its neighbour. The metal stock was only a flat circular plate, or flanch, projecting from the box which received the axle, and another flat plate fitted upon it, and bound against the former by screw-bolts, one passing through each arm; these rendered the wheel very strong.

Mr. Wilks took a patent in 1813 for a metal stock, in which there are complete cells for each spoke, and the cells are dove-tailed; that is, they are made larger at the central part than at the outside, to prevent them from drawing out, and

they are firmly pressed into the dove-tails by the screw-bolts which confine the moveable plate.

Wheels for railway-waggons are made of cast-iron, and usually all in one piece; but this is objectionable, because the unequal contraction of the arms and rim of the wheel in cooling, after the wheel is cast, puts the different parts on a strain, and they frequently break without any adequate force. It is better to cast the rim in one piece and the arms in another, and put them together with screw-bolts, or rivets. Mr. Hawks had a patent for this in 1807. In this way, the rims may be replaced when worn out.

The Axle-trees for Wheels of Carriages.—The strong iron bar which extends across beneath the wood-work of the carriage, is called the axle-tree; the round parts at each end, on which the wheels run, are called the axle-arms; and the part or stem between them, which is fixed beneath the wood-work of the carriage, is also called the axle-tree. In the form of the latter parts there are but two sorts, the one made flat, and called a bedded axle-tree, it being sunk all its length in the under side of the timbers of the carriage; the other is made of an octagon form, and flat only at the ends where they are bedded.

The axle-arms on which the wheels turn should be made perfectly round, and somewhat stronger at the shoulder than at the extreme end, which is screwed to receive a nut, through which and the axle-tree the linch-pin passes, to keep all tight. The nuts are made with a collar at the face; and a temporary collar, or washer, is driven on the back of the arms, which form two shoulders for the wheel to wear against, and helps to preserve the greafe from running out, and to prevent dirt from getting in.

As the axle-trees are the principal or only support of the carriage, every attention and care should be fixed in the selection of good iron; and to see that they be well wrought, and of sufficient strength, rather going to the extreme of strength, than risking the life of the passenger by the over-setting of the carriage, which mostly happens when an axle-tree breaks.

By the bend of the axle-trees, the wheels are regulated to any width at bottom, to suit the track of the roads in which they are to run, and are confined in the carriage by means of clips, hoops, and bolts. The shape of the axle-tree between the shoulders varies according to the situation they are placed in, or the form of the timber of the carriage with which they are united; those are the most firm that are flat, bedded in the timber. Axle-tree boxes for wheels are of various kinds; those which are frequently called long-pipe, or wheel-boxes, are long tubes fitted accurately to the arms of the axle-trees, and securely fixed in the wheel-stocks, or naves; they are usually made of wrought sheet-iron of a substance proportioned to the weight of the carriage; their use is to contain a supply of greafe, and to prevent the effects of friction, whereby the wheels are much assisted in their motion. These are now used instead of the old cast-iron boxes, which for quick travelling-carriages are totally out of use, being found injurious to the axle-trees, by cutting them at those parts they wear against, so as to occasion a frequent lining of the arms; but with the wrought metal boxes this is seldom necessary.

There are many sorts of axle-trees and boxes invented various ways, with a view of attaining the following advantages; *viz.* To contain a longer supply of greafe or oil, to be more durable, to secure the wheels, and to lessen the draught. Those are all certainly great advantages, and though the expence is great, the utility of either of them must be more than adequate to it, and merits more general notice.

Some of these inventors even pretend that all these advantages are combined in one axle-tree; but the generality extend to the advantage only of retaining a supply of oil, and remaining perfect to a considerable length of time. The common sort of axle-tree and box, which is most generally used, is simple and cheap in comparison with the others.

Common Axle-tree.—The arms of the axle-tree are made round, but rather of a conical form, strongest at the back or shoulders, tapering to the lynch end, which is screwed for a nut, and also has a small hole for a lynch-pin, which prevents the nut from coming off; at the body-end is a washer or collar for the back of the wheel-stock to wear against. The box is made of sheet-iron, proportioned in substance to the weight or size of the axle-tree, having the edges of the plate, of which it is formed, welded in a ridge which projects on the outside; this secures the box in the nave of the wheel, and prevents it turning round therein.

The nut which screws on the end of the axle-arm has a broad face to lie flat against the wheel, and is tapped or screwed to receive the screw-end of the axle-tree. Each of those nuts must turn on the screw the same way the wheel goes, and must have a notch for the lynch-pin to pass through, for the purpose of securing the nut from turning off.

The box is what, of the axle-tree, wears most, and is frequently obliged to be refitted to the arms; otherwise they give to the wheel while in use an unsteady motion, and soon exhaust their stock of grease.

Those that are well fitted will contain their supply for about one week with regular use, or a journey of one hundred miles. They wear at the rate of one set of boxes to every two sets of wheels, and require in that time to be twice or thrice taken out of the wheels and refitted to the axle-tree arms.

Axle-trees with Friction-Wheels.—These were invented by Mr. Garnet, at least the best kind, which are made in a very ingenious manner. The wheel-box is made much larger than the axle-tree, in such manner that the space all round between them may receive a number of rollers which fill it up. (See a description in the article *MILL-Work*.) Mr. Garnet had a patent in 1784, and for some years manufactured great numbers; but being very expensive, they fell into disuse, although very complete. This invention has been lately revived by Mr. Panter.

The Patent Anti-Abrition Axle-tree and Box.—The proposed advantages of this axle-tree are, ease of draft by diminution of friction; the retention of oil to supply a month's use; the ease with which it is replenished without taking off the wheels; the great security for the wheels, which it prevents from coming off, and the carriage from overturning, if even the arm of the axle-tree should break; and their durability, and even improvement by wear. Those axle-trees, if made with the securing-collar, for the wheels need no nut or lynch-pin, as is generally used, but the wheel may be taken off and put on as easily as those on the common principle.

These axle-arms are reduced at the bottom from a perfect round, and grooved, to receive two small rollers, on which the weight of the carriage is borne, and which greatly facilitates the motion, in the same manner as blocks of stone or timber, which require to be removed by the assistance of rollers. These rollers form the outer circumference of the axle-trees at bottom, which are reduced to give a bearing only on them. A circular box or cistern is provided to contain a supply of oil; it is closely fitted to the back of the inner end of the wheel-stock, and fixed by three bolts. The oil is here contained within three circular recesses, and

oozes through small channels on the arm of the axle-tree, which it feeds for a considerable time. This oil-box is made of cast-metal, and has a cap projecting behind over the axle-tree, which prevents the dirt from getting into the box. This axle-tree is also provided with what is called the wheel-security, or strap-washer. It is an iron collar, fitted on the external part of the wheel-stock, and confined between the reservoir and stock, lying as it were in a groove, so that the collar cannot come off. This collar has two lugs or straps extending backwards some distance along that part of the axle-tree which is bedded in the wood-work, where it is fixed by a nut-screw. By means of this strap-washer, the wheel is secured to the bedded part of the axle-tree; and should the axle-arm within the wheel break, the wheel will continue to act.

The cap of this axle-tree is also fixed on the outside part of the wheel-stocks; by the same three bolts which fasten the oil-box, and by means of a screw-plug in the cap, the axle-tree and reservoir are replenished with oil. The box is of the same form as the common box, only made of a very hard durable metal, of a considerable thickness, and is made in proportion to the weight of the carriage.

Collinge's Patent Cylinder Axle-tree and Box.—These axle-trees have been a considerable time in use, and their advantages have been proved in the length of time they wear, in the silent and steady motion they preserve to the wheels, in the advantage of retaining the oil to prosecute a journey of two thousand miles without being once replenished; and lastly, they are very durable, and but little subject to be out of order.

The axle-tree arm is made as perfectly cylindrical as possible, and of a peculiar hard substance; the middle of the cylinder is reduced, to contain the oil necessary to feed the axle-trees; so that the two bearings are at the two ends of the axle, which has an internal shoulder, against which the inner end of the wheel-box takes its bearings. Behind this shoulder is a deep groove for a washer to preserve the oil, and prevent noise in its use; also a rim, or hollow box, on the collar of the axle-tree, which overlaps part of the inner end of the wheel-stock to keep out dirt, and answer the use of a cuttoo. The extreme end of the arm is double-screwed, to receive two nuts for securing the wheel: the one screw turns the way of the wheel; the other the reverse, and is meant as an additional security.

The box is made of a very hard metal, nicely polished, and fitted to the arms, having a circular recess all round at the end nearest the carriage, for containing there a supply of oil. The box is longer than the part which bears on the axle; and the projecting part beyond the bearing at each end is bored out larger than the arm. The back projection fits close to the rim of the collar, which it covers: the fore one projects outwards beyond the surface of the wheel-stock, and is screwed on the inside to receive the screw of the cap.

There are many other patents for axle-trees to wheels; but as few of them have come into use, we shall only notice Messrs. Flight and Brook's patent axles. The axle is fixed fast to the nave of the wheel, by passing through it. This axle turns round within the wheel-box; whereas in others the wheel-box turns round upon the axle.

The axle is cylindrical, and is received into a cylindrical box or tube in the end of the iron axle-tree, which is firmly bolted to the under-side of the timber of the carriage. To hold the axle in its place, and prevent it from drawing out of the box, the end of the axle is reduced to a knob or button, which adheres to the end of the axle by a small neck.

neck. This button is fitted and received into a socket, in which it can freely turn round, but cannot draw out endways. It is made in a piece of metal, which is cylindrical on the outside, and of the same size as the axle. It is made in two halves, which separate longitudinally to introduce or take out the button at the end of the axle; but when the two halves are put together, the socket-piece forms as it were a continuation of the axle. When the axle is put into the box with this socket-piece at the end of it, the two halves of the socket will be confined together, so that they cannot separate; and to prevent them from drawing out of the box, a screw-bolt is put through the box, and passes through both halves of the socket: this holds the socket and the axle in their places.

Mr. Ackermann has recently obtained a patent (1818) for a valuable improvement in the application of the fore-wheels to four-wheeled carriages. In our article *COACH-MAKING*, vol. viii. we have described those methods which were then known of applying the fore-wheels, so as to make a four-wheel carriage turn with safety, and in a small space. See also *PERCH*.

Mr. Ackermann's improvement effects this in the most perfect manner. Each of the fore axle-trees is connected with the carriage by means of a vertical axle, formed in the same piece with the horizontal axle, and upon which the wheel turns, the two axles being situated at right angles to each other. These vertical axles are fitted into sockets, formed at the two extremities of a cross beam of the frame of the carriage, which is called the fore-spring transom. Upon these axles, as centres of motion, the axle-arms and wheels can be turned about horizontally, in order to place them obliquely to the direction of the hinder-wheels when the carriage is required to turn; but each axle turns upon a separate centre of motion, and these centres are very near to their respective wheels, being at the extremities of the cross-beam or transom; hence the fore-wheels do not change their place upon the ground when they are placed obliquely.

In a common carriage, the axles of the two fore-wheels are both fixed to one piece of timber, called the axle-bed, which is placed beneath the fore-transom, and united to it by a vertical pin called the perch-bolt, passing through the middle of the axle-bed. On this pin, as a centre, the axle-bed is turned round. When the wheels are to be placed obliquely, it is evident, that, in so turning upon a single centre, one wheel must advance forwards, and the other must retreat backwards, so as to diminish the bearing of the carriage-wheels on the ground in a lateral direction, and at the same time the horses are pulling in that direction which tends to overturn the carriage. Another inconvenience is, that one of the wheels will touch the perch of the carriage, if placed very oblique.

In the new improvement, two separate centres of motion being used, and these being removed from each other as far as possible, many desirable properties are attained.

To give the oblique direction to the wheels, each vertical axle has a lever proceeding backwards from it; and these two levers are united together by a connecting-bar, which obliges both axles to move at the same time with a sympathetic action. The pole of the carriage is united to the piece, called the futchel, in the usual manner; and the futchel is united to the spring-transom by a perch-bolt, in the usual position; also the hinder end of the futchel is jointed to the middle of the connecting-bar, between the two levers of the vertical axles. The connecting-bar likewise answers the purpose of a sway-bar.

When the horses move to one side, the pole and futchel

turn upon the perch-bolt, as a lever upon a centre of motion; and the extreme end of the futchel acts upon both vertical axles at once by means of the connecting-bar, so as to place both of the fore-wheels in an oblique direction. This is the invention of M. Lankensperger of Munich.

WHEEL, Aristotle's. See *ROTA Aristotelica*.

WHEEL, Blowing, a machine contrived by Dr. Defagulier for drawing out the foul air of any place, or for forcing in fresh, or doing both successively, without opening doors or windows. See *Phil. Transf. N^o 437*.

The intention of this machine is the same as that of Dr. Hales's ventilator, but not so effectual, nor so convenient. See *Defagul. Course of Exper. Philos. vol. ii. p. 563. 568*.

This wheel is also called a *centrifugal wheel*, because it drives the air with a centrifugal force.

WHEELS, Bushes or Boxes of, the inside metal linings of the naves. See *WHEEL*.

WHEEL, Cutting Roller, in Agriculture, a tool of the cutting and reducing sort, used for the purpose of working over crops in some cases. In Oxfordshire a cutting roller of this sort has been invented, which is composed of twelve wheels, two inches and a half in thickness; and between each of them is a space of two inches and a half. They are three feet in diameter. It is a load in working so as to be sufficient exertion for a strong team to draw it: it is passed over wheat after it has been sown, or after it is come up; and if dry, crops and crops. It has also been used in the spring upon wheat; it leaves the surface rough in a sort of diamond forms, which is found very beneficial in some of the wheat-lands of that district. It is also capable of being used in breaking down the surface of stiff tillage-land in many other cases and circumstances.

WHEEL, Draining, a wheel constructed for the purpose of cutting or making drains. Wheels differently formed are used for this sort of work. In Essex they employ workmen who make use of a cast-iron wheel which weighs about four hundred weight, and which is four feet in diameter; the cutting edge or extreme circumference of the wheel being half an inch in thickness, which increases in this way as it approaches towards the nave or centre; and will, at fifteen inches deep, scour out or cut a drain half an inch wide at the bottom, and four inches wide at the top. The wheel is so placed in a frame, that it may be loaded at pleasure, and be made to pass to a greater or less depth, as the nature of the land may be.

The writer of the Middlesex Report on Agriculture advises the use of a common six-inch cart-wheel, on the felly of which, all round, a sort of ridge-formed addition of wood is to be fixed, and a rim of iron of a triangular shape fastened to the wood. A wheel of this kind put on the axle of a cart, in the usual way, will, of course, rest on the edge of the rim of iron; and which, on driving the horse forward, will make a small indent or depression in the ground merely by the revolution of it; but in order to make it press down to the depth of six or eight inches, that side of the cart should be loaded with stones, iron ballast, or any other heavy material that may happen to be at hand, until the whole of the parts, if necessary, sink into the soil. It would however be as well, or better, it is said, if the rim parts added to the wheel were in one piece of cast-iron; as the increased weight of it would enable it to cut or sink without the aid of ballast, or with less than usual. The cart should then be drawn along in such a manner, that the cutting or depressing wheel may revolve where the drains are intended to be made. In land that is in ridges and furrows, it will sometimes be necessary to draw the wheel along every furrow.

furrow. When the ground is without ridge and furrow, the wheel should be drawn over it in parallel lines, five or ten yards distant from each other. The wheel on the other end of the axle is a common six-inch wheel, supporting only the empty side of the cart, consequently will not cut or depress the ground.

The advantage of this contrivance is, that it makes an indent or depression in the surface soil of soft wet clayey grasslands, sufficient to carry off the water during the same winter, by pressing down the sward and herbage without destroying it. In the following spring, these drains will be nearly grown up, and clothed with grass; consequently, there will be nothing taken from the pasturage or the scythe. It is necessary to observe, that the wheel must be drawn over the ground every year on the approach of winter. With it, and two old horses, a stout boy or man may, it is said, drain from ten to twenty acres in eight hours.

It may be found very useful in the grass and hay land districts about the metropolis and other places. See SURFACE Draining.

WHEEL, *Measuring*. See PERAMBULATOR.

WHEEL, *Orffyreus's*. See ORFFYREUS.

WHEEL, *Persian*. See PERSIAN.

WHEEL-Ploughs, in *Agriculture*, all such ploughs as are constructed with wheels. See PLOUGH.

WHEEL, *Potter's*, is a round board attached to a lathe, and capable of being moved by it, either rapidly or more slowly, as occasion may require. This round board moves in a horizontal position; and when in use, the clay which is to be fashioned is fixed on the centre of it; and it is put in motion either by a person who constantly attends it when at work, or by means of a treadle which is moved by the foot of the workman himself.

As the clay revolves upon this machine, the workman either models it by his fingers, or forms it, by means of an instrument which he holds in his hand, into any kind of circular shape that he may desire; and when the object is to make a number of vessels exactly similar to each other, the size is generally determined by a gauge fixed without the circumference of the revolving wheel, but projecting over it in such a manner that, whenever the yielding clay is spread out until it touch this gauge, the artist knows that the article which he is making has attained the exact figure which he intends.

The potter's wheel has lately been much improved by adapting a strap to it, which passes over a large taper cylinder of wood, and by means of which the artist is enabled to increase or diminish the rapidity of the motion at pleasure. This contrivance is known to mechanics by the name of the *cone pulley*. Parkes's *Essays*, vol. iii. See POTTERY.

WHEELS, *Tires of*, the iron hoops or bars which are put round the outsides of the felly-parts of them.

WHEEL, *Water*. See WATER.

WHEEL is also a name of a kind of punishment, which great criminals are put to in divers countries.

In France, their assassins, parricides, and robbers on the highway, were condemned to the wheel; *i. e.* had their bones first broken with an iron bar on a scaffold, and then to be exposed and left to expire on the circumference of a wheel. In Germany, they broke their bones first on the wheel itself.

This cruel punishment was unknown to the ancients; as is observed by Cujas. It is not certain who was the inventor. Its first introduction was in Germany. It was, indeed, but rarely practised any where else, till the time of Francis I. of France; who, by an edict of the year 1534, appointed

it to be inflicted on robbers on the highway. Richelet dates the edict in the year 1538, and quotes Brodæus, *Miscell.* lib. ii. cap. 10.

WHEEL, in the *Military Art*, is the word of command, when a battalion or squadron is to alter its front, either one way, or the other.

To wheel to the right, the man in the right angle is to turn very slowly, and every one to wheel from the left to the right, regarding him as their centre; and *vice versa*, when they are to *wheel to the left*.

When a division of men are on the march, if the word be, *wheel to the right*, or *to the left*; then the right or left-hand man keeps his ground, turning only on his heel, and the rest of the rank move about quick, till they make an even line with the said right or left-hand man.

Squadrons of horse wheel after much the same manner.

In wheeling, the circle is conceived to be divided into four parts; whence wheeling to the right or left respects only a quarter of a circle; and wheeling to the right or left about, refers to half of the circle. In performing this motion, each man moves more quickly or slowly, according to his distance from the right to the left. See BATTALION.

WHEEL, or *Catherine-Wheel*, in *Architecture*, frequently occurs in the upper part of the north and south transepts of our ancient cathedrals, being divided by mullions, like the spokes of a wheel: it resembles the engine of torture said to have been prepared by the tyrant Maximin to tear the flesh of St. Catherine of Alexandria. The French, who have generally placed a large wheel of this sort by way of a western window to their cathedrals, call it *Rose du Portail*.

WHEEL-Animals, *Brachionus*, in *Zoology*, a genus of animalcules, which have an apparatus of arms for taking their prey. (See BRACHIONUS.) This apparatus has been supposed, by microscopical writers, to be a kind of wheels. This is one of the smaller animalcules; and is described by Dr. Hill to be, when at rest, of a plain smooth body, conic figure, obtuse at the posterior extremity, and open at the anterior, of a dusky olive colour, and semi-transparent. When in motion it protrudes from the open extremity a part of its naked body, to the whole of which this outer conic body seems to be but a case or sheath; from the end of this exerted part of the body, it thrusts out two protuberances, which give it the appearance of a double head; and in each of these is discovered an apparatus in continual motion, appearing to be a rotatory one, though really a vibratory one very quickly repeated. Each of these protruded bodies has six arms inserted into it, which it continually shuts and opens over one another. Each of the arms is furnished with a double series of fibres at its edge, which, being expanded, cause it to spread to considerable breadth. There are several species of this genus.

The wheel animal, described by Mr. Baker, has two seeming wheels, with a great many teeth or notches coming from its head, and turning round as it were on an axis. On the least touch, this animalcule draws its wheel into its body into the sheath; but when every thing is quiet, throws them out and works them again.

In order to find these animalcules, choose such roots of duck-weed as are long, and proceed from strong old plants, for the young roots seldom afford any; they should not be covered with that rough matter which is frequently found about them, nor any way tending to decay, as they will often be.

In the water found remaining in the leaden pipes, or gutters on the tops of houses, there are also found great

numbers of these wheel-animals. These are of a different species from the former; and when the water dries away, they contract their bodies into a globular or oval figure, and are then of a reddish colour, and remain mixed with the dirt, growing together in a lump as hard as clay. This, whenever it is put in water, in half an hour's time discovers the animals' living again, and as brisk as ever; and they have been found to be living in this manner, after the matter had been kept dry twenty months.

It should seem from this, that as the water dries up, their pores become shut in the manner of those of such animals as remain torpid for the winter; and that when they find water come on again from rain, they then unfold themselves, and live and feed as long as it lasts. Baker's Microscope.

WHEEL-Barometer. See BAROMETER.

WHEEL-Boats denote a sort of boats with wheels, to be used alternately on the water and upon inclined planes or rail-ways.

WHEEL-Fire, among *Chemists*, a fire used for calcining metallic substances; properly called *ignis rotæ*.

It is a fire which only encompasses the crucible, coppel, or melting-pot, around the sides, without touching it in any part.

WHEEL-Shaped, in *Botany*, a term exclusively appropriated to the *corolla*. See ROTATA.

WHEELER, among *Brickmakers*. See BRICK.

WHEELER, in *Geography*, a river of Wales, which runs into the Clyde, 3 miles N. of Denbigh.

WHEELING, a post-town of Virginia, at the union of Wheeling Creek with the Ohio; 54 miles S.W. of Pittsburgh.—Also, a township of Ohio, in the county of Belmont, with 656 inhabitants.

WHEELING Creek, a river of Virginia, which runs into the Ohio, N. lat. 39° 56'. W. long. 80° 45'.

WHEELING Planks are stout planks which the navigators or workmen upon a canal make use of to wheel upon.

WHEELOCK, in *Geography*, a township of Vermont, in the county of Caledonia, containing 963 inhabitants; 60 miles N. of Windfor.—Also, a river of Cheshire, which runs into the Dane.

WHEELWRIGHT GUT, a creek on the north-west coast of the island of St. Christopher, with a bar before its entrance.

WHEEZING and *BLOWING*, in *Animals*, a sort of affection in the breathing, especially in horses, in which they draw their breath with difficulty and noise.

The generality of people make this and purfines, in horses, the same distemper; but the more judicious always distinguish it, as wholly different from that. Purfines proceeds always from a stuffing or oppression of the lungs; but this wheezing is only owing to the narrowness of the passage between the bones and gristles of the nose.

The horses that are most of all afflicted with this distemper do not want wind; for notwithstanding that they wheeze excessively when they are exercised, yet all the time their flanks are not moved, but kept in the same condition that they were when the creature stood still. The dealers call this sort of horses blowers, and though there is no real harm in the thing, it is a disagreeable quality, and few people will choose them that have much service for them.

There are some horses which have a natural defect in their breathing, which makes it at all times attended with some difficulty, but not with the wheezing before mentioned; these are called thick-winded horses.

People who are careful in the buying of horses, will purchase neither of these kinds; but there is this caution to be observed in regard to this defect, that it often seems to be in horses where it really is not. When a horse has been kept a long time in the stable without exercise, he will at the first riding be out of breath, and fetch it in a difficult and painful manner, though he be neither a blower nor thick-winded; but all this will go off with a little exercise.

There are some temporary wheezers and blowers among horses: these at times rattle, and make a great noise through their noses in taking breath; but the complaint goes off and returns. This is only occasioned by a great quantity of phlegm, for their flanks do not redouble with it at the worst of times, nor have they any cough with it; so that there is no danger of their being purfy.

It is probable, that in these cases there is, for the most part, some sort of spasm or constriction in the chests of the animals, as they are much relieved in most instances by the use of warm mashes, and by having their fodder made moist.

How far remedies that remove spasm might be useful has not yet been fully tried, either in these or other sorts of animals.

WHELDY-AHAD LAKE, in *Geography*, a lake of North America. N. lat. 61° 40'. W. long. 103° 30'.

WHELERA, in *Botany*, was so named by Schreber, in memory of the celebrated English traveller and botanist, sir George Wheler, Bart. F.R.S. who died in 1724, aged 74. His "Journey into Greece," however faulty in the plates, is a book of the first authority.—Schreb. Gen. 725.—Class and order, *Polygamia Monœcia*, Schreb.; rather *Pentandria Monogynia*. Nat. Ord. *Sapotæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, roundish, erect, permanent segments, shorter than the corolla. *Cor.* of one petal, bell-shaped, spreading, in five deep, ovate, acute segments. Nectary somewhat pitcher-shaped, in the bottom of the flower. *Stam.* Filaments five, awl-shaped, rather longer than the corolla; anthers roundish. There are five other filaments, alternate with the former, and similar to them, but shorter, and destitute of anthers. *Pist.* Germen superior, conical, villos; style thread-shaped, twice the length of the corolla; stigma simple. *Peric.* Drupa roundish. *Seed.* Nut large, ovate, of one, two, or three cells.

Some flowers, on the same plant, want the pistil, others the stamens.

This is Schreber's generic description, from which we learn, without difficulty, the natural order of the plant. But it is one of those genera, like his *VILLARIA*, (see that article,) which cannot be determined without an examination of the author's herbarium. Such also are his *MEYERA*, already described; his *WOLFIA*, and *XYSTRIS*, which will occur hereafter. We trust some botanist, who may have the opportunity of clearing up these, the only important obscurities in Schreber's classical work, will favour the world with an explanation of them. *SPARTINA* is in the same predicament, except that professor Schrader appears to be acquainted with it. See that article.

WHELKS, *Buccina*, in *Natural History*. See SHELLS, and TRUMPET-Shell.

WHELPS. See HOUND.

WHELPS, in a *Ship*. See CAPSTAN.

WHENNUIA, in *Geography*, a small island among those called the Society islands, near Otaha.

WHERLICOTES, a sort of open chariots, of the ancient Britons' invention, used by persons of quality before the invention of coaches.

WHERN,

WHERN, in *Natural History*, a name given by some of our miners to a kind of stone found in strata, but of the hardness and fineness of flint. It is called also *chert* and *nicomia*.

WHERRY. See **VESSEL, BOAT, &c.**

WHERRY, in *Rural Economy*, a provincial term applied to a liquor made from the pulp of crabs after the verjuice is expressed. It has not unfrequently the name of crab-werry. See **VERJUICE**.

WHERWELL, in *Geography*, a village of England, in the county of Hants. Here was formerly a convent of nuns, founded by Elfrida, widow of king Edgar, to expiate the murder of her first husband, Ethelwolf, and her son-in-law, prince Edward; 4 miles S. of Andover.

WHET-SLATE, or **WHETSTONE-SLATE**, and **HONE**, French *novaculite*, and *schiste coticule*, in *Mineralogy*, a variety of slate used for sharpening iron and steel instruments. (See **SLATE**.) The light green coloured variety from the Levant is considered as the most valuable. It is brought in masses to Marseilles, and is there cut into pieces of various sizes, and afterwards ground with sand or sand-stone, and then polished with pumice and tripoli. These whet-stones or hones should be kept in damp places, for when much exposed to the sun, they become too hard and dry for many purposes. The powder of whet-slate is used for cutting and polishing metals, and is by artists considered as a variety of emery. It is necessary to the perfection of hones, that they should contain no intermixed substances, such as quartz, &c. (Jamefon's *Mineralogy*, second edition, vol. i.) Whet-slate, approaching in appearance to foreign hones, occurs in the upper part of Long Sleddale, in Westmoreland; and at Howth, in Dublin bay.

WHET-STONE, in *Rural Economy*, the soft stone usually made use of in sharpening edge-tools of different kinds.

WHEWER, in *Ornithology*, a name used in some parts of England for the common wigeon. See **DUCK**.

WHEY, the serum, or watery part of milk.

In many disorders of the human body, where the stomach will not bear milk, or when it is not proper, for other reasons, whey may be given with great success.

We have a dissertation of Fred. Hoffmann on this subject, *De Saluberrima feri Lactis Virtute*. Oper. tom. vi. p. 9. This author recommends a particular kind of serum or whey, made by evaporating milk to a dryness, and mixing the residuum with water. See **MILK**.

There are various methods of making whey, vulgarly known. That with oranges is very agreeable, and much recommended by Dr. Cheyne, in his *Nat. Method of curing Diseases*.

WHEY, in *Rural Economy*, a term applied to the serous part of milk, from which the curd has been separated. There are two sorts or colours of whey, the green and white; the latter is by much the richer, and that which chiefly affords the butter of this kind. See **DAIRYING**.

WHEY, Alum, Serum Aluminosum, a whey made with alum; in the proportion of two drachms of alum to one pint of cow's milk boiled.

This whey is beneficial in an immoderate flow of the menses, and in a diabetes, or excessive discharge of urine. The dose is two, three, or four ounces, as the stomach will bear it, three times a day.

WHEY-Butter, that which is made from the cream of whey. It is commonly made in abundance in the dairy districts after cheese-making begins. See **DAIRYING**.

WHEY-Cream, that which is collected from off the whey

and made into butter of this sort. A dairy cow usually affords eight or ten ounces of it weekly in some dairies. See **DAIRYING**.

WHEY, Mustard, is made by boiling of bruised mustard-seed, an ounce and a half, in milk and water, of each a pint, till the curd is perfectly separated, and straining the whey through a cloth. This, says Dr. Buchan, is the most elegant, and by no means the least efficacious method of exhibiting mustard: it warms and invigorates the habit, and promotes the different secretions. Hence, in the low state of nervous fevers, it will often supply the place of wine: it is also of use in the chronic rheumatism, palsy, dropfy, &c. The dose is a tea-cupful four or five times a day, which may be sweetened with a little sugar.

WHEY, Scalding of, the heating of it and pouring it over the curd in making cheese.

WHEY, Scorbutic, is made by boiling half a pint of the scorbutic juices, in a quart of cow's milk. The scorbutic plants are, bitter oranges, brook-lime, garden scurvy-grass, and water-cresses.

WHEY Springy Cheese, the eyeey spongy cheese of this sort, caused by being improperly made.

WHEY-Tub, the vessel in which the whey stands for yielding the cream, &c.

WHICHCOTE, BENJAMIN, in *Biography*, an eminent divine of the English church, was born in March 1609-10, of an ancient family at Whichcote-hall, in Shropshire; and having finished his education at Emanuel college, Cambridge, in 1626, he passed through the common degrees, and became fellow of his college in 1633, and a distinguished tutor. In 1636 he took orders, and established a lecture at Trinity church, in Cambridge, and continued it for nearly twenty years. It was his great object to substitute a spirit of sober and rational piety in the university, instead of the enthusiasm and fanaticism which then prevailed; nor were his efforts for this purpose unavailing. Being married, and having settled on a living in Somersetshire, his connection with the university was for some time interrupted; but in 1644 he returned to it, as the successor of Dr. Samuel Collins, the ejected provost of King's college, allowing to him part of the emoluments that belonged to this office. In 1649 he took the degree of D.D., and was presented to the rectory of Milton, in Cambridgeshire. He is represented by bishop Burnet as a friend to liberty of conscience, and in order to promote rational and sublime ideas of religion, he advised the students to peruse the ancient philosophers, especially Plato, Cicero, and Plotinus. At the Restoration he was deprived of his provostship, and removing to London, he was chosen minister of St. Anne's, Blackfriars, in 1662. Afterwards, when his church was burnt down, he retired to Milton, but he was recalled to London to the vicarage of St. Lawrence, Jewry, by presentation from the crown; and he served this church with great reputation till his death in 1683.

After his death, a volume of his "Select Sermons," 8vo. 1698, was published, with a preface by lord Shaftesbury, author of the "Characteristics," by whom they were valued, because the author recognized that sense of the beauty of virtue which is the foundation of his moral system. Two more volumes were afterwards published by Dr. Jeffery, archdeacon of Norwich, who, in 1703, presented to the public "Moral and Religious Aphorisms collected from Dr. Whichcote's MS. Papers." A fourth volume was published by Dr. S. Clarke in 1707, and reprinted in 1753 by Dr. Salter, with large additions, and eight letters between the author and some of his friends on important subjects.

These several publications assigned to Dr. Whichcote a high rank among the rational divines of this country, and particularly at the period in which he lived. Biog. Brit.

WHICKS, in *Agriculture*, a term sometimes applied to young plants of the white-thorn kind, as well as to couch-grass. See QUICKS and COUCH.

WHIDAH, in *Geography*, a kingdom of Africa, on the Slave Coast; extending about ten miles along the coast, and about seven miles into the land. Europeans who have been in Whidah speak of the country with rapture, and extol it as one of the most beautiful in the world. The trees are straight, tall, and disposed in the most regular order, which present to the eye fine long groves and avenues, clear of all brush-wood and weeds. The verdure of the meadows, the richness of the fields, clothed with three different kinds of corn, beans, roots, and fruits, and the multitude of houses, form a most delightful prospect. A perpetual spring and autumn succeed each other; for no sooner has the husbandman cut his corn, than he again ploughs and sows the ground; yet it is not worn out; the next crop puts forth with the same vigour as the former, as if nature here were inexhaustible. Certain it is, that the kingdom of Whidah is so populous, that one single village contains as many inhabitants as several entire kingdoms on the coast of Guinea; and yet they stand so close, that one is amazed how the most fertile land on earth can supply the number of people contained in so small a compass. One may compare the whole kingdom to a great city, divided by gardens, lawns, and groves, instead of streets, the villages in Whidah not being a musket-shot distant from each other. Some are the king's, some the viceroy's villages, and others are built and peopled by particular private families. The former are the largest and best built; but the latter the best cultivated, if there be any difference in a country so uniformly rich and beautiful. Notwithstanding the small extent of this kingdom, it is divided into twenty-six provinces, which take their names from the capital towns. Those small states are distributed among the chief lords of the kingdom, and become hereditary in their families. The king of Whidah, who is only their chief, presides particularly in the province of Sabi, or Xabier, which is the principal province of the kingdom, as the city of the same name is the capital of the whole. Bujis, which the French by corruption call bauges, pass frequently for money at their fairs in the country: this is a small white shell, of the size and shape of an olive. In the kingdom of Whidah and Ardra, these bujis serve equally for dress and money, for ornament and use. They pierce each shell with an iron made for that purpose; forty of them they string upon a cord, which they call *seuze*, and the Portuguese *toquos*: five of these strings compose what the Portuguese call a *gallinba*, and the Negroes a *fore*. By these the exchange of gold-dust is rated, and the price of slaves determined. The Europeans, the nobility of Whidah, and all the rich negroes, are carried, when they go abroad, in hammocs, or palanquins, on the shoulders of slaves. The natives of Whidah are in general tall, well made, straight, and robust. Their complexion is black, but not so glossy as that of the people on the Gold Coast, and still less than those of Senegal and the river Gambia. They excel all other negroes in industry and vigilance. Idleness is the favourite vice of the Africans in general; here, on the contrary, both sexes are so laborious and diligent, that they never desist till they have finished their undertaking; carrying the same spirit of perseverance into every action of their life. Besides agriculture, from which none but the king and a few persons of the first distinction are exempted, they employ

themselves in several kinds of manufactures: they spin cotton-yarn, weave fine cotton cloths, make calabasses, wooden vessels, plates, and dishes; likewise assagayes, and smiths'-work in greater perfection than any other people on the coast. Whilst the men are thus employed, the women brew pito, and dress provisions, which, with their husbands' merchandize, they carry for sale to market. As to religion, Bosman is of opinion, that the piety of this country is founded upon no other principles than those of interest and superstition. In the latter, they exceed all other nations; for allowing, says he, the ancient heathens to value themselves upon thirty thousand deities, I dare venture to affirm that the natives of Whidah may lay just claim to four times that number. However, he believes that they have a faint idea of the one true God, to whom they attribute omnipotence and ubiquity. One of their principal fetiches, or deities, is the snake, which they invoke in extreme wet, dry, or barren seasons, on all occasions relating to their government, civil policy, and cattle; in a word, on all the great difficulties and occurrences of life. This snake has a large round head, beautiful piercing eyes, a short pointed tongue, resembling a dart: its pace slow and solemn, except when it seizes on its prey, then quick and rapid; its tail sharp and short, its skin of an elegant smoothness, adorned with beautiful colours, upon a light-grey ground. It is amazingly tame and familiar, permitting itself to be approached, and even handled: they have a mortal antipathy to all venomous serpents: they attack them wherever they find them, as if they had pleasure in delivering mankind from their poison. The Europeans find no difficulty in familiarizing themselves to these inoffensive animals, with which they play without any dread or apprehension of danger. There is no fear of mistaking them for the poisonous serpents, the colour and size sufficiently distinguishing them. The negroes entertain a notion that the first progenitor of this race of snakes is still living, and growing to an enormous bulk. When the English first settled in Whidah, the captain having unshipped his goods on shore, the sailors found at night one of those snakes in their magazine, which they ignorantly killed, and threw upon the bank, without dreaming of any bad consequences. The negroes, who soon discovered the sacrilege, and had it confirmed by the acknowledgment of the English mariners, were not long in avenging the horrid impiety, by a method no less horrible. All the inhabitants of the province assembled; they attacked the English, massacred them all to a man, and consumed their bodies and goods in the fire they had set to the warehouse. Animals of all kinds are punished with death for injuring a snake. In 1697, a hog having had the presumption to destroy one of these deities, an order was issued for a general slaughter of swine throughout the kingdom, and the destruction of the whole race was hardly prevented by the interposition of the king.

WHIDAH, a town of Africa, in the country of Whidah. N. lat. $6^{\circ} 25'$. E. long. $1^{\circ} 24'$.

WHIDBY'S ISLAND, an island in the Gulf of Georgia, near the west coast of America; about 36 miles long, and from 2 to 6 broad: so named from Mr. Whidby, an officer under captain Vancouver. N. lat. $48^{\circ} 10'$. E. long. $237^{\circ} 40'$.

WHIDDY, an island in Bantry bay, in the county of Cork, Ireland, about 2 miles from the town of Bantry. It is a pleasant island of a triangular form, and the soil is excellent.

WHIFF, in *Ichthyology*, the name of a sort of flounder. WHIFFLER of a *Company*, in London, a young free-

man,

man, who goes before, and waits on the company, on occasions of public solemnities.

WHIG, in *Rural Economy*, a term provincially applied to acidulated whey, which is sometimes mixed with butter-milk and sweet herbs, to give it a flavour, when it becomes a good cooling summer beverage.

WHIGS, a party or faction in England, opposite to the Tories.

The origin of the names of these two mighty factions is very obscure. If some little trivial circumstance or adventure, which escapes the knowledge of mankind, gives name to a party, which afterwards becomes famous, posterity labours in vain to find the original of such a name: it searches the sources, forms conjectures, invents reasons, and sometimes, indeed, meets the truth, but always without knowing it assuredly.

Thus, in France, the Calvinists are called Huguenots; yet nobody was ever able certainly to assign the cause of that appellation.

Whig is a Scottish, and, some say too, an Irish word, literally signifying *whey*. *Tory* is another Irish word, signifying a *robber* or *highwayman*.

Under the reign of king Charles II., while his brother, then duke of York, was obliged to retire into Scotland, there were two parties formed in that country. That of the duke was strongest, persecuted the other, and frequently reduced them to fly into the mountains and woods; where those unhappy fugitives had often no other subsistence for a long time but cows' milk. Hence they called these their adversaries *tories*, *q. d. robbers*; and the tories, upbraiding them with their unhappiness, from the milk on which they lived, called them *whigs*. From Scotland, the two names came over with the duke into England.

Others give a different origin and etymology of the two words, for which see **TORIES**.

Bishop Burnet gives another etymology of the term *whigs*. The south-west counties of Scotland, he says, are supplied with corn from Leith; and from a word *whiggam*, used by the carriers in driving their horses, all that drove were called *whiggamoors*, and by contraction *whigs*.

He adds, that in the year 1648, after the news of the defeat of duke Hamilton, who was charged with being a confederate with the malignants, or royal party, in England, the ministers animated their people to rise, and march to Edinburgh: who came up, marching each at the head of his parish, with an unheard-of fury, praying and preaching all the way as they came. The marquis of Argyll and his party came and headed them. This was called the *whiggamoor's* inroad; and ever after, all that opposed the court were contemptuously called *whigs*: and from Scotland the term was brought into England. Burnet's Hist. of his Own Times, vol. i. p. 43.

For the distinguishing principles and characters of the whigs, see **TORIES**.

WHIMBRAL. See **SCOLOPAX** *Guarauna*, and **PHÆOPUS**.

WHIMSEY, WATER, a machine consisting of a reservoir, or bucket of water, employed for raising another bucket, filled with coals or other materials, by means of a rope or chain, coiled round a cylinder or drum, or two drums of different sizes. When the bucket of water in this machine has reached the bottom of the pit or well, a valve is opened by striking against a pin, and lets out the water. In a machine of this kind, used in the duke of Bridgewater's coal-works, the water descends thirty yards, and raises a smaller quantity of coals from a depth of sixty. In such cases, supposing the action to be single, and the stream of water to

be unemployed during the descent of the reservoir, a considerable preponderance may be advantageously employed in giving velocity to the weights, provided that the machinery be not liable to injury from their impulse.

WHIN, in *Botany*. See **GORSE**.

WHIN, in *Agriculture*, a term sometimes applied to furze; which, when cut in the sap and bruised in a proper way by flails, or in other modes, makes an excellent green food in winter for horses, which eat and thrive on it well. It is also useful in some measure to sheep-stock, as well as to bees. Its encroaches on land may be easily and readily prevented by proper means being taken for the purpose. See **FURZE**.

WHIN, in *Gardening*. See **ULEX**.

WHIN-Ashes, in *Agriculture* and *Planting*, the ashes produced in burning whins; which have lately been found of great benefit in planting young trees, as well as on land for other purposes, promoting their growth in a very high degree. If the land to be planted be suitable, they are advised to be carefully spread and ploughed in, if of quantity sufficient, over the whole field, otherwise only on the wet or colder spots or parts of it. But if the ground be such that it will not admit of ploughing, the ashes should be mixed up with part of the best surface mould, to keep them from blowing abroad; and in the process of pitting, a little of this compost should be intimately mixed with the mould of each pit; previously distributing it in small heaps at convenient distances for facilitating the operation: and this extra trouble will be amply repaid by the progress the plants will make in consequence.

WHIN-Axe, in *Agriculture*, an instrument employed for extirpating whins from laud in many cases. It is an implement that has one end like a common axe, with four inches of face; and the other like an adze, also with four inches of face; whereby the person using it, continuing in the same position by simply turning it in the hand, can make cuts at right angles with one another, as circumstances may require. The head of the tool may be about eight inches in length, weighing from three to four pounds; and the handle, of ash, about four feet long.

WHIN, Petty, a name given to a species of *ononis*, or rest-harrow.

WHIN, Petty, in *Gardening*. See **GENISTA**.

WHINCHAT, in *Ornithology*, the English name of the *motacilla rubetra* of Linnæus.

It is of the common size of the water-wagtail. Its head, neck, and back, are of a reddish-brown, with regular rows of black spots. Over each eye is a narrow white stroke, and beneath that a broad bed of black, extending from the bill to the hind part of the head; the breast is of a reddish-yellow; the belly paler; the quill-feathers are brown, edged with a yellowish-brown; the upper part of the wing is marked with two white spots; the lower part of the tail is white, the two middle feathers excepted, which are wholly black; the upper part of the other is of the same colour.

The colours are very uncertain in this bird, and it often much resembles the stone-chatter; but may always, by an accurate observer, be distinguished from that bird by the white spots in its wings, by the whiteness of the under part of its tail, and the white lines on its head.

The colours of the female are much less agreeable than those of the male; in lieu of the white and black marks on the cheeks is one broad pale brown one; and the white on the wings is in much less quantity than that of the male.

In the north of England, the whinchat is a bird of passage;

fage; in the fourth he continues the whole year. Ray and Pennant.

WHINE, a hunting term, used in respect of the cry of an otter.

WHINEBACH, in *Geography*, a town of Africa, on the Gold Coast. N. lat. $5^{\circ} 30'$. W. long. $1^{\circ} 30'$.

WHIN-STONE, in *Geology*, the provincial name given, in many parts of England and Scotland, to basaltic rocks: it is also applied by miners to designate every kind of dark-coloured and hard unstratified rock, which resists the point of the pick. Many geologists in this country class all basaltic or trap rocks under the term whin-stone. See **TRAP**.

The substance which fills very large mineral veins is generally dark basalt, or green-stone; hence these veins are most frequently called whin-dykes. These veins being harder than most of the rocks which they intersect, remain when the surface on each side of them is washed away, forming enormous walls extending into the sea, or rising above the level of the country in various parts of their course, and may often be traced for many leagues. They occur in the counties of Northumberland and Durham, and on the coasts of Scotland; and when broken down, they form reefs of rock or islands. The Farn islands, off the coast of Northumberland, are parts of a basaltic dyke. When whin-dykes cross rivers, they form ledges of rock constituting fords; or, if very abrupt, they hold up the water on one side and form cascades. The Cleveland basalt, or whin-dyke, described in Mr. Bakewell's *Introduction to Geology*, (see **VEINS, Mineral**;) has been traced from the coast of Yorkshire seventy miles into the western part of Durham.

Under the article *Mineral VEINS*, we have observed, that when whin-dykes intersect coal strata, they produce a change in the substance of the coal, and also of the other strata, similar to what might have been expected from a stream of melted lava; and we have recently observed a similar effect produced on primitive rocks of gneiss, in the vicinity of Aberdeen, by contact with a powerful whin-dyke. The whin-stone is also changed near its contact with the gneiss into a reddish horn-stone. In other parts, it is a dark granular basalt or green-stone. The gneiss has lost its characteristic structure, and becomes porphyritic when near the whin-dyke. Between whin-dykes and the rocks which they intersect, there is sometimes a seam of soft argillaceous earth interposed, which is washed out when they are near the sea-coast, leaving the whin-stone like a wall placed between two perpendicular precipices. Sometimes the internal part of a whin-dyke will be composed of soft iron-clay; in other instances, the dyke will be composed of solid blocks or prisms of basalt separated by similar clay. In some whin-dykes, the substance which fills them appears a compact and solid mass of whin-stone, which, however, will divide into four, five, or six-sided prisms, arranged horizontally.

These are perfectly similar to the perpendicular basaltic columns in structure, differing only in their position. There is a dyke traversing the basaltic strata of the Giant's Causeway, on the coast of Antrim, in which this peculiarity of structure is remarkably displayed. It intersects beds of columnar basalt, in which the columns are arranged with great regularity, and are perpendicular to the horizon; but the whole dyke is composed of small prisms of basalt placed horizontally, or at right angles with the former. Some of these prisms do not exceed an inch in diameter, others are much larger; they are for the most part extremely regular, and are articulated or jointed.

It has been supposed with much probability, that the different arrangement of the columnar structure in the beds and in the dyke, is to be attributed to the different circum-

stances under which they were solidified. If the beds have once flowed as lava under the surface of the ocean, the basalt would begin to cool and crystallize from the upper and lower surface. That this has probably been the case may be inferred from these beds resting on strata that contain marine organic remains, and which must, therefore, have been formed under the bed of the ocean.

The perpendicular dykes intersecting rocks already formed would begin to cool from the sides with which they were in contact, and the process would proceed laterally.

In some instances, we find whin-dykes principally composed of globular masses of stone separated by a large quantity of soft clay, and the globular masses are incrustated with ochreous clay: probably the whole of the clay in such dykes has been formed from the decomposition of the basaltic masses by the action of water percolating them.

Whin-stone dykes present so many analogies with volcanic rocks in their composition, and the effects which they produce on the strata that they pass through, that we are led to refer their origin to the action of subterranean fire cracking the upper rocks and strata, and forcing the melted matter into the rent. Under the article **VOLCANO**, we have stated many instances of vast rents made in the earth, and filled by eruptions of lava; these rents so filled with lava may be considered as whin-dykes of recent formation. This is further confirmed by the observations of M. Cordier, (see **VOLCANIC Productions**;) who has shewn that the substance which fills both are essentially the same, being principally composed of feldspar and augite, with iron-sand and olivine. Whin-stone not only occupies the cavities of perpendicular dykes; but it appears to have been, in many instances, found laterally between the regular strata, producing singular contortions and dislocations, and almost always effecting a change in the substance of the rock with which it comes in contact. Sometimes it produces a change in the form of the bed or stratum which it has passed through, breaking it into distinct masses, or bending it in different directions, or enveloping large parts of it in the basalt or whin-stone. Of this a remarkable instance is described in the third volume of the *Transactions of the Geological Society*, occurring on the north coast of Ireland, in the county of Antrim. (See *Plate IV. fig. 4. Geology.*) *aaa* represents a bed of chalk singularly bent, and completely enveloped in the basalt which forms a part of the basaltic range extending from the Giant's Causeway.

The beds of chalk and the other strata on this coast are frequently intersected by whin-dykes, and a most remarkable change is observed in the structure of the chalk in the vicinity of these dykes. In immediate contact with the whin-stone, and to a considerable distance on each side, the chalk is converted into marble, having the granular texture of primitive lime-stone, or what the French call *calcaire saccharoide*, from its resemblance to the grain of loaf-sugar, (see *Plate IV. fig. 5. Geology*;) which represents two adjoining whin-dykes *ab*, intersecting the chalk *ccc*; the dyke *a* is thirty feet in width, the dyke *b* twenty feet, and the intervening mass of chalk twenty feet. The mass of chalk between the two large dykes is intersected in a zigzag direction by a smaller dyke. To a certain distance from the whin-stone, the chalk is perfectly crystalline, but it gradually approaches to the character of the chalk at a greater distance from the dyke. In various parts of the world we observe trap or whin-stone occurring in apparently regular beds, either covering stratified rocks, or interposed between them; such have been called by the Wernerian geologists *stætz* trap-rocks, and their occurrence in this position has been urged as an argument for the aqueous formation of such

such rocks. But it is well known to practical miners, that these beds are much more variable in their thickness than the regular strata, sometimes measuring twenty, thirty, or forty feet or more; and in other parts, the same bed will diminish to a few feet, or entirely terminate. In the isle of Skye, according to the description of Dr. Maccullock, in the third and fourth volumes of the Transactions of the Geological Society, the whin-stone is spread over the regular strata in beds, or forms detached conical caps. It is also to be seen interposed between the strata, and may be traced for more than a mile in continuous regular beds; but, says Dr. Maccullock, "there are no instances but where the alternating beds of trap detach veins or dykes from the lower to the upper beds; or the trap, quitting the interval between two given beds of lime-stone or sand-stone, makes its way across the one immediately above or below, and then proceeds with a regularity as great between some other pair of proximate strata." And he adds, "I have no doubt, could such extensive exposure of the strata be oftener procured, all the instances of supposed alternating trap with regular stratified rocks would prove similar to the above." These observations, which might be confirmed by numerous other instances, tend to prove, that whin-dykes, and many of the interposed strata of whin-stone, are of posterior formation to the rocks in which they occur, and have been forced between the strata in a fluid state, and subsequently consolidated. The whin-dykes, or perpendicular veins, are the channels through which the basalt flowed up; but by superincumbent pressure, it has been driven laterally at different elevations. As beds of whin-stone occur in different rocks, it is probable, and almost certain, that they have had different epochs of formation; and of course some of the beds of whin-stone, which are covered by stratified rocks containing many organic remains, may have flowed as beds of lava under the ocean, and have been again covered with other strata, on which again a second torrent of lava bursting from below may have flown and formed an upper bed. It is well known that the beds of toad-stone in Derbyshire, which are interposed between the mountain lime-stone of that district, cut off the metallic veins; but they are found again on sinking through the toad-stone into the lower lime-stone. This stone, which varies from a hard, compact whin-stone or trap, to a soft amygdaloidal wacke, (see *TOAD-STONE* and *WACKE*,) is supposed, by Mr. Whitehurst, to have flowed between the beds of lime-stone after the formation of metallic veins; and, could we admit the hypothesis, it would satisfactorily explain the cause of their disappearance in the toad-stone. But though there are many instances of the vein entirely disappearing in the latter rock, there are others in which a narrow vein passes through the toad-stone, though it is never productive of ore, being filled with calcareous spar, and a few particles only of galene. The occurrence of these veins in the toad-stone proves that this rock was not found between the lime-stone after the formation of metallic veins. Some softer whin-stone rocks, of the species called by mineralogists wacke, (see *WACKE*,) contain cavities lined, or partly filled with zeolites, agates, or calcareous spar; and some of these rocks envelope marine organic remains, particularly a rock of this kind near Berkley in Gloucestershire. The Euganean mountains are composed of a similar rock, and also contain marine remains. These rocks have probably been formed by muddy eruptions of submarine volcanoes, similar to what take place from some of the American volcanoes at the present time; and it is not improbable but that these two modes of formation may have given rise to that diversity which we observe in rocks of this class, the softer and more earthy being the products of

aqueous and muddy eruptions, and the harder and more crystalline the products of igneous fusion. See *TRAP*, and *VOLCANIC PRODUCTS*.

WHIP, or **WHIP-STAFF**, in a *Ship*, a piece of timber in form of a strong staff, fastened into the helm, for the steersman, in small ships, to hold in his hand; thereby to move the rudder, and direct the ship.

WHIP denotes also a sort of small tackle, formed by the communication of a rope either with a single immovable block, or with two blocks, one of which is fixed, and the other moveable. It is generally used to hoist light bodies, as empty casks, &c. out of a ship's hold, which is accordingly called whipping them up. *Falconer*.

To whip is to tie a piece of pack-thread, spun-yarn, &c. about the end of a rope, to prevent it from being untwisted and unloosened.

WHIP, in *Rural Economy*, the lash attached to flexible rods or other substances and contrivances, for the purpose of driving teams.

WHIP-GRAFTING, in *Gardening*, a particular mode of performing the operation. A sort of root-whip-grafting is advised by *Agricola*, in which a graft or scion is taken from a young tree, and a small piece of the root of another tree of the same kind, or like it; or otherwise, pieces of roots cut off from other trees in transplanting: these are whip-grafted together, taking care that the two but ends of the graft and root be united, and that the rind of the root join that of the graft; then plant the root with the part of the scion under-ground. See *GRAFTING*, and *STOCKS*, *Apple-grafting in*.

WHIP-POOR-WILL. See *CAPRIMULGUS Virginianus*.

WHIP-REIN, in *Agriculture*, a term used to signify a rein formed of cord or leather, by which a plough or other sort of team is directed in working. See *REIN*.

WHIP-REIN-PLOUGH, a term applied to a small plough, drawn by two horses, or oxen, which are guided and directed by proper reins of this sort, and so made as to serve the ploughman in the way of a whip, in driving them while he holds the plough.

WHIP-SAW. See *WHIP-SAW*.

WHIPLADE, in *Husbandry*, a term used by the farmers in some places for a particular sort of cart, whose hinder part is made up of boards after the manner of a dung-cart, having also a head of boards, and shambles over the thills; this head being so as either to be taken out or left in. The cart may be indifferently used to carry dung or other things; dung when the head is in, and corn, &c. when it is taken out.

WHIPPANY, in *Geography*, a town of New Jersey; 20 miles W.N.W. of New York.

WHIPPER. See *FISHING*.

WHIPPING, a term used by *Anglers*, when they fasten a line to the hook or rod.

The word is also taken for the casting in of the hook, and drawing it gently on the water.

WHIPPING, in *Law*, denotes an ignominious punishment inflicted on persons guilty of petty larceny, &c.

WHIPPING WHEAT, in *Agriculture*, a term applied to the practice in some of the northern districts, by which the wheat-crops are lashed or whipped out on a wooden or watted frame-work contrived for the purpose. The former is constructed by nailing two or more thick boards in a slanting manner, to the height of about two and a half, or three feet, on a sort of frame of suitable strength, supported by legs, having the upper part a little rounded, and made smooth. This, which is termed the whipping or lashing frame, is placed

placed in some convenient situation, so as to prevent the grain from flying about during the operation, which is then begun. Where the latter contrivance is made use of, the frame is woven with strong sticks, in the manner of a hurdle, being placed in the same situation when used.

The process is performed by taking large handfuls of the corn in the straw by the butt end, and striking the top or ear-ends over the upper part of the frame, so as to force out the grain from the ears of the top part, without breaking the straw, which in this way becomes much better for thatch, and at the same time the grain is less injured than by the flail method of threshing it out. The butt parts of the straw are sometimes afterwards thrashed over, in order to get out any wheat that may have been left in the short ears. This is an excellent mode of providing seed-wheat, as the finest grain is chiefly procured.

And it is suggested, too, as a particularly good method in cases where wheat is infected with the smut, as during the operation of threshing, the flail breaks the smut-balls, and reduces them to a powdery state, which causes the good wheat to have a blacker appearance than would otherwise be the case when ground. It may likewise be used to advantage with other sorts of grain in some cases.

The above is also a term sometimes applied in the northern districts, to the practice of striking it over a stone or other such contrivance, in order to get out the grain, and leave the straw in an unbroken state. In this way it is sometimes termed *lashing*. It is an excellent practice in getting out this sort of grain in many points of view, when on a small scale, but it is not well suited to large concerns. See **THRESHING**.

WHIPPLE-TREE, a term used to signify the bar or wooden part of the contrivance by which a horse or team is attached to a plough, harrow, or any other sort of implement of these kinds. They are of different sizes and forms, according to the nature of the teams and other circumstances. See **SWINGLE-TREE**, *Indented*.

WHIPSTITCH, a term not unfrequently used in ploughing to signify a sort of half-ploughing, or what in many places is termed *raftering*. It is principally made use of for keeping the land more dry and healthy in the winter season. See **RAFTERING**.

WHIPSTITCHING, the practice of working tillage-land in somewhat the raftering manner. It is a method often employed for turning up stubbles of the wheat and other kinds in the winter time, instead of making a fallow. The best mode of doing it in this intention is first to make what is called a whipstitch, rafter, or sort of half-ploughing of the land; and that when come back again to the same furrow, to turn them both over; the top parts of both furrows being thus turned in the middle, which leaves the space of four inches betwixt each furrow: then ploughing the land across the old furrows. If land lies ever so wet in winter, by ploughing in this manner, it may be kept dry and in a healthy state. It is necessary, too, to strike up the old furrows every day before leaving the ground; and to let the main drains be kept well open to receive the water from the furrows in the land: by this means, the frost will be admitted four inches deeper than in the case of a flat fallow-work.

This mode of tillage is that which is sometimes called double whipstitching in some districts and places.

Some prefer it before all other methods for winter-tillage, as it brings the land into much better condition for cultivation than twice fallowing.

WHIPT SYLLABUB. See **SYLLABUB**.

WHIRL-POOL, an eddy, vortex, or gulf, where the

water is continually turning round. See **GULPH**, **EDDY**, **VORTEX**, &c.

These in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a remarkable marine whirlpool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among those islands. Wherever it appears, it is very furious, and boats, &c. would inevitably be drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing, in the boat with them; as soon as they perceive the whirlpool, they toss this within its vortex, keeping themselves out; this substance, whatever it be, is immediately received in the centre, and carried under water; and as soon as this is done, the surface of the place where the whirl-pool becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile distant from the first. Sibbald's *Prodr. Hist. Scot.*

WHIRLIGIG, in *Military Antiquities*, an instrument of punishment formerly much used for trifling offences, committed by petit cutlers, Jews, brawling women, and such persons. This was a kind of circular wooden cage, which turned on a pivot; and when set in motion, whirled round with such an amazing velocity, that the delinquent became extremely sick, and commonly made discharges through every operation of the body.

WHIRLING-TABLE, a machine contrived for exhibiting and demonstrating the principal laws of gravitation, and of the planetary motions in curvilinear orbits. *AA* (*Plate XXI. fig. 13. Astronomy*) is a strong frame of wood, *B* a winch fixed on the axis *C* of the wheel *D*, round which is the catgut-string *F*, which also goes round the small wheels *G* and *K*, crossing between them and the great wheel *D*. On the upper end of the axis of the wheel *G*, above the frame, is fixed the round board *d*, to which may be occasionally fixed the bearer *MSX*. On the axis of the wheel *H* is fixed the bearer *NTZ*, and when the winch *B* is turned, the wheels and bearers are put into a whirling motion. Each bearer has two wires, *WX* and *YZ*, fixed and screwed tight into them at the ends by nuts on the outside; and when the nuts are unscrewed, the wires may be drawn out in order to change the balls *U*, *V*, which slide upon the wires by means of brass loops fixed into the balls, and preventing their touching the wood below them. Through each ball there passes a silk line, which is fixed to it at any length from the centre of the bearer to its end by a nut-screw at the top of the ball; the shank of the screw going into the centre of the ball, and pressing the line against the under side of the hole which it goes through. The line goes from the ball, and under a small pulley fixed in the middle of the bearer; then up through a socket in the round plate (*S* and *T*) in the middle of each bearer; then through a slit in the middle of a square top (*O* and *P*) of each tower, and going over a small pulley on the top comes down again the same way, and is at last fastened to the upper end of the socket fixed in the middle of the round plate above-mentioned. Each of these plates, *S* and *T*, has four round holes near their edges, by which they slide up and down upon the wires which make the corner of each tower. The balls and plates being thus connected, each by its particular line, it is plain that if the balls be drawn outward, or towards the ends *M* and *N* of their respective bearers,

WHIRLING-TABLE.

bearers, the round plates S and T will be drawn up to the top of their respective towers O and P.

There are several brass weights, some of two, some of three, and others of four ounces, to be occasionally put within the towers O and P, upon the round plates S and T; each weight having a round hole in the middle of it, for going upon the fockets or axes of the plates, and being slit from the edge to the hole, that it may slip over the line which comes from each ball to its respective plate.

For a specimen of the experiments which may be made with this machine, we shall subjoin the following.

1. Removing the bearer M X, put the loop of the line b , to which the ivory ball a is fastened, over a pin in the centre of the board d , and turn the winch B; and the ball will not immediately begin to move with the board, but, on account of its inactivity, endeavour to remain in its state of rest. But when the ball has acquired the same velocity with the board, it will remain upon the same part of the board, having no relative motion upon it. However, if the board be suddenly stopped, the ball will continue to revolve upon it, until the friction thereof stops its motion; so that matter resists every change of state, from that of rest to that of motion, and *vice versa*.

2. Put a longer cord to this ball; let it down through the hollow axis of the bearer M X and wheel G, and fix a weight to the end of the cord below the machine; and this weight, if left at liberty, will draw the ball from the edge of the whirling-board to its centre. Draw off the ball a little from its centre, and turn the winch; then the ball will go round and round with the board, and gradually fly farther from the centre, raising up the weight below the machine; and thus it appears that all bodies revolving in circles, have a tendency to fly off from these circles, and must be retained in them by some power proceeding from or tending to the centre of motion. Stop the machine, and the ball will continue to revolve for some time upon the board; but as the friction gradually stops its motion, the weight acting upon it will bring it nearer and nearer to the centre in every revolution, till it brings it quite thither. Hence it appears, that if the planets met with any resistance in going round the sun, its attractive power would bring them nearer and nearer to it in every revolution, till they fell into it.

3. Take hold of the cord below the machine with one hand, and with the other throw the ball upon the round board as it were at right angles to the cord, and it will revolve upon the board. Then, observing the velocity of its motion, pull the cord below the machine, and thus bring the ball nearer the centre of the board, and the ball will be seen to revolve with an increasing velocity, as it approaches the centre: and thus the planets which are nearest the sun perform quicker revolutions than those which are more remote, and move with greater velocity in every part of their respective circles.

4. Remove the ball a , and apply the bearer M X, whose centre of motion is in its middle at w , directly over the centre of the whirling-board d . Then put two balls (V and U) of equal weights upon their bearing wires, and having fixed them at equal distances from their respective centres of motion w and x upon their silk cords, by the screw-nuts, put equal weights in the towers O and P. Lastly, put the catgut-strings E and F upon the grooves G and H of the small wheels, which, being of equal diameters, will give equal velocities to the bearers above, when the winch B is turned; and the balls U and V will fly off toward M and N, and raise the weights in the towers at the same instant. This shews, that when bodies of equal quantities of matter

revolve in equal circles with equal velocities, their centrifugal forces are equal.

5. Take away these equal balls, and put a ball of six ounces into the bearer M X, at a sixth part of the distance wz from the centre, and put a ball of one ounce into the opposite bearer, at the whole distance $xy = wz$; and fix the balls at these distances on their cords, by the screw-nuts at the top: then the ball U, which is six times as heavy as the ball V, will be at only a sixth part of the distance from its centre of motion; and consequently will revolve in a circle of only a sixth part of the circumference of the circle in which V revolves. Let equal weights be put into the towers, and the winch be turned; which (as the catgut-string is on equal wheels below) will cause the balls to revolve in equal times: but V will move six times as fast as U, because it revolves in a circle of six times its radius, and both the weights in the towers will rise at once. Hence it appears, that the centrifugal forces of revolving bodies are in direct proportion to their quantities of matter multiplied into their respective velocities, or into their distances from the centres of their respective circles.

If these two balls be fixed at equal distances from their respective centres of motion, they will move with equal velocities; and if the tower O has six times as much weight put into it as the tower P has, the balls will raise their weights exactly at the same moment: *i. e.* the ball U, being six times as heavy as the ball V, has six times as much centrifugal force in describing an equal circle with an equal velocity.

6. Let two balls, U and V, of equal weights be fixed on their cords at equal distances from their respective centres of motion w and x ; and let the catgut-string E be put round the wheel K (whose circumference is only half that of the wheel H or G) and over the pulley s to keep it tight, and let four times as much weight be put into the tower P, as in the tower O. Then turn the winch B, and the ball V will revolve twice as fast as the ball U in a circle of the same diameter, because they are equi-distant from the centres of the circles in which they revolve; and the weights in the towers will both rise at the same instant, which shews that a double velocity in the same circle will exactly balance a quadruple power of attraction in the centre of the circle: for the weights in the towers may be considered as the attractive forces in the centres, acting upon the revolving balls; which, moving in equal circles, are as if they both moved in the same circle. Whence it appears, that if bodies of equal weights revolve in equal circles with unequal velocities, their centrifugal forces are as the squares of the velocities.

7. The catgut-string remaining as before, let the distance of the ball V from the centre x be equal to 2 of the divisions on its bearer; and the distance of the ball U from the centre w be 3 and a sixth part; the balls themselves being equally heavy, and V making two revolutions by turning the winch, whilst U makes one; so that if we suppose the ball V to revolve in one moment, the ball U will revolve in two moments, the squares of which are 1 and 4: therefore, the square of the period of V is contained 4 times in the square of the period of U. But the distance of V is 2, the cube of which is 8, and the distance of U is $3\frac{1}{6}$, the cube of which is 32 very nearly, in which 8 is contained 4 times: and therefore the squares of the periods of V and U are to one another as the cubes of their distances from x and w , the centres of their respective circles. And if the weight in the tower O be 4 ounces, equal to the square of 2, the distance of V from the centre x ; and the weight in the tower P be 10 ounces, nearly equal to the square of $3\frac{1}{6}$, the distance

distance of U from w ; it will be found, upon turning the machine by the winch, that the balls U and V will raise their respective weights at very nearly the same instant of time. This experiment confirms the famous proposition of Kepler, *viz.* that the squares of the periodical times of the planets round the sun are in proportion as the cubes of their distances from him; and that the sun's attraction is inversely as the square of the distance from his centre.

8. Take off the string E from the wheels D and H, and let the string F remain upon the wheels D and G; take away also the bearer MX from the whirling-board d , and instead of it put on the machine A B (*Plate XXI. fig. 14. Astronomy*), fixing it to the centre of the board by the pins c and d , so that the end ef may rise above the board to an angle of 30 or 40 degrees. On the upper part of this machine, there are two glass tubes a and b , close stopped at both ends; each tube being about three-quarters full of water. In the tube a is a little quicksilver, which naturally falls down to the end a in the water; and in the tube b is a small cork, floating on the top of the water, and small enough to rise or fall in the tube. While the board b with this machine upon it continues at rest, the quicksilver lies at the bottom of the tube a , and the cork floats on the water near the top of the tube b . But, upon turning the winch and moving the machine, the contents of each tube will fly off towards the uppermost ends, which are farthest from the centre of motion: the heaviest with the greatest force. Consequently, the quicksilver in the tube a will fly off quite to the end f , occupying its bulk of space and excluding the water, which is lighter than itself: but the water in the tube b , flying off to its higher end e , will exclude the cork from that place, and cause it to descend toward the lowest end of the tube; for the heavier body, having the greater centrifugal force, will possess the upper part of the tube, and the lighter body will keep between the heavier and the lower part.

This experiment demonstrates the absurdity of the Cartesian doctrine of vortices: for, if the planet be more dense or heavy than its bulk of the vortex, it will fly off in it farther and farther from the sun; if less dense, it will come down to the lowest part of the vortex, at the sun: and the whole vortex itself, unless prevented by some obstacle, would fly quite off, together with the planets.

9. If a body be so placed upon the whirling-board of the machine (*fig. 13.*) that the centre of gravity of the body be directly over the centre of the board, and the board be moved ever so rapidly by the winch B, the body will turn round with the board, without moving from its middle; for, as all parts of the body are in equilibrio round its centre of gravity, and the centre of gravity is at rest in the centre of motion, the centrifugal force of all parts of the body will be equal at equal distances from its centre of motion, and therefore the body will remain in its place. But if the centre of gravity be placed ever so little out of the centre of motion, and the machine be turned swiftly round, the body will fly off towards that side of the board on which its centre of gravity lies. Then, if the wire C (*fig. 15.*) with its little ball B be taken away from the semi-globe A, and the flat side ef of the semi-globe be laid upon the whirling-board, so that their centres may coincide; if then the board be turned ever so quickly by the winch, the semi-globe will remain where it was placed: but if the wire C be screwed into the semi-globe at d , the whole becomes one body, whose centre of gravity is at or near d . Fix the pin c in the centre of the whirling-board, and let the deep groove b cut in the flat side of the semi-globe be put upon the pin, so that the pin may be in the centre of A (*see fig. 16.* where the

groove is represented at b), and let the board be turned by the winch, which will carry the little ball B (*fig. 15.*) with its wire C, and the semi-globe A, round the centre pin c ; and then, the centrifugal force of the little ball B, weighing one ounce, will be so great as to draw off the semi-globe A, weighing two pounds, until the end of the groove at e strikes against the pin c , and so prevents A from going any farther: otherwise, the centrifugal force of B would have been great enough to have carried A quite off the whirling-board. Hence we see, that if the sun were placed in the centre of the orbits of the planets, it could not possibly remain there; for the centrifugal forces of the planets would carry them quite off, and the sun with them; especially when several of them happened to be in one quarter of the heavens. For the sun and planets are as much connected by the mutual attraction subsisting between them, as the bodies A and B are by the wire C fixed into them both. And even if there were but one planet in the whole heavens to go round ever so large a sun in the centre of its orbit, its centrifugal force would soon carry off both itself and the sun: for the greatest body placed in any part of free space could be easily moved; because, if there were no other body to attract it, it would have no weight or gravity of itself, and consequently, though it could have no tendency of itself to remove from that part of space, yet it might be very easily moved by any other substance.

10. As the centrifugal force of the light body B will not allow the heavy body A to remain in the centre of motion, even though it be twenty-four times as heavy as B; let the ball A (*fig. 17.*) weighing six ounces be connected by the wire C with the ball B, weighing one ounce; and let the fork E be fixed into the centre of the whirling-board; then, hang the balls upon the fork by the wire C in such a manner, that they may exactly balance each other, which will be when the centre of gravity between them, in the wire at d , is supported by the fork. And this centre of gravity is as much nearer to the centre of the ball A than to the centre of B, as A is heavier than B; allowing for the weight of the wire on each side of the fork. Then, let the machine be moved, and the balls A and B will go round their common centre of gravity d , keeping their balance, because either will not allow the other to fly off with it. For, supposing the ball B to be only one ounce in weight, and the ball A to be six ounces; then, if the wire C were equally heavy on each side of the fork, the centre of gravity d would be six times as far from the centre of B, as from the centre of A, and consequently B will revolve with a velocity six times as great as A does; which will give B six times as much centrifugal force as any single ounce of A has: but then, as B is only one ounce, and A six ounces, the whole centrifugal force of A will exactly balance that of B; and therefore each body will detain the other, so as to make it keep in its circle.

Hence it appears, that the sun and planets must all move round the common centre of gravity of the whole system, in order to preserve that just balance which takes place among them.

11. Take away the forks and balls from the whirling-board, and place the trough A B (*fig. 18.*) thereon, fixing its centre to that of the board by the pin H. In this trough are two balls D and E of unequal weights, connected by a wire f , and made to slide easily upon the wire C stretched from end to end of the trough, and made fast by nut-screws on the outside of the ends. Place these balls on the wire C, so that their common centre of gravity g may be directly over the centre of the whirling-board. Then, turn the machine by the winch ever so swiftly, and the trough

trough and balls will go round their centre of gravity, so as neither of them will fly off; because, on account of the equilibrium, each ball detains the other with an equal force acting against it. But if the ball E be drawn a little more towards the end of the trough at A, it will remove the centre of gravity towards that end from the centre of motion; and then, upon turning the machine, the little ball E will fly off, and strike with a considerable force against the end A, and draw the great ball B into the middle of the trough. Or, if the great ball D be drawn towards the end B of the trough, so that the centre of gravity may be a little towards that end from the centre of motion, and the machine be turned by the winch, the great ball D will fly off, and strike violently against the end B of the trough, and will bring the little ball E into the middle of it. If the trough be not made very strong, the ball D will break through it.

12. Mr. Ferguson has explained the reason why the tides rise at the same time on opposite sides of the earth, and consequently in opposite directions, by the following new experiment on the whirling-table. For this purpose, let *abcd* (fig. 19.) represent the earth, with its side *c* turned toward the moon, which will then attract the water so as to raise them from *c* to *g*: and in order to shew that they will rise as high at the same time on the opposite side from *a* to *e*; let a plate A B (fig. 20.) be fixed upon one end of the flat bar D C, with such a circle drawn upon it as *abcd* (fig. 19.) to represent the round figure of the earth and sea; and an ellipse as *efgb* to represent the swelling of the tide at *e* and *g*, occasioned by the influence of the moon. Over this plate A B suspend the three ivory balls *e, f, g*, by the silk lines *b, i, k*, fastened to the tops of the crooked wires H, I, K, so that the ball at *e* may hang freely over the side of the circle *c*, which is farthest from the moon M at the other end of the bar; the ball at *f* over the centre, and the ball at *g* over the side of the circle *g*, which is nearest the moon. The ball *f* may represent the centre of the earth, the ball *g* water on the side next the moon, and the ball *e* water on the opposite side. On the back of the moon M is fixed a short bar N parallel to the horizon, and there are three holes in it above the little weights *p, q, r*. A silk thread *o* is tied to the line *k*, close above the ball *g*, and passing by one side of the moon M goes through a hole in the bar N, and has the weight *p* hung to it. Such another thread *n* is tied to the line *i*, close above the ball *f*, and passing through the centre of the moon M and middle of the bar N, has the weight *q* hung to it, which is lighter than the weight *p*. A third thread *m* is tied to the line *b*, close above the ball *e*, and passing by the other side of the moon M, through the bar N, has the weight *r* hung to it, which is lighter than the weight *q*. The use of these three unequal weights is to represent the moon's unequal attraction at different distances from her; so that if they are left at liberty, they will draw all the three balls towards the moon with different degrees of force, and cause them to appear as in fig. 21, in which case they are evidently farther from each other than if they hung freely by the perpendicular lines *b, i, k*. Hence it appears, that as the moon attracts the side of the earth which is nearest her with a greater degree of force than she does the centre of the earth, she will draw the water on that side more than the centre, and cause it to rise on that side; and as she draws the centre more than the opposite side, the centre will recede farther from the surface of the water on that opposite side, and leave it as high there as she raised it on the side next her. For, as the centre will be in the middle between the tops of the opposite elevations,

they must of course be equally high on both sides at the same time.

However, upon the supposition, the earth and moon would soon come together; and this would be the case, if they had not a motion round their common centre of gravity, to produce a degree of centrifugal force, sufficient to balance their mutual attraction. Such motion they have; for as the moon revolves in her orbit every month at the distance of 240,000 miles from the earth's centre, and of 234,000 miles from the centre of gravity of the earth and moon, the earth also goes round the same centre of gravity every month at the distance of 6000 miles from it, *i. e.* from it to the centre of the earth. But the diameter of the earth being, in round numbers, 8000 miles, its side next the moon is only 2000 miles from the common centre of gravity of the earth and moon, its centre 6000 miles from it; and its farthest side from the moon 10,000 miles. Consequently the centrifugal forces of these parts are as 2000, 6000, and 10,000; *i. e.* the centrifugal force of any side of the earth, when it is turned toward the moon, is five times as great as when it is turned toward the moon. And as the moon's attraction, expressed by the number 6000, at the earth's centre, keeps the earth from flying out of this monthly circle, it must be greater than the centrifugal force of the waters on the side next her; and consequently, her greater degree of attraction on that side is sufficient to raise them; but as her attraction on the opposite side is less than the centrifugal force of the water there, the excess of this force is sufficient to raise the water just as high on the opposite side.

To prove this experimentally, let the bar D C with its furniture be fixed on the whirling-board of the machine, (fig. 14.) by pushing the pin P into the centre of the board; which pin is the centre of gravity of the whole bar with its three balls *e, f, g*, and moon M. Now, if the whirling-board and bar be turned slowly round by the winch, till the ball *f* hangs over the centre of the circle, as in fig. 22, the ball *g* will be kept towards the moon by the heaviest weight *p* (fig. 20.), and the ball *e*, on account of its greater centrifugal force, and the less weight *r*, will fly off as far to the other side, as in fig. 22. And thus, whilst the machine is kept turning, the balls *e* and *g* will hang over the ends of the ellipse *lfk*. So that the centrifugal force of the ball *e* will exceed the moon's attraction just as much as her attraction exceeds the centrifugal force of the ball *g*, whilst her attraction just balances the centrifugal force of the ball *f*, and makes it keep in its circle. Hence it is evident, that the tides must rise to equal heights at the same time on opposite sides of the earth. See Ferguson's Lectures on Mechanics, lect. 2, and Desag. Ex. Phil. vol. i. lect. 5.

WHIRL-WIND, a wind that rises suddenly, and is exceedingly rapid and impetuous when risen, but is soon spent. In this case, the gusts of wind proceed from different quarters at the same time, and meet in a certain place, where the air acquires a circular, or rotatory, or screw-like motion, either ascending or descending, as it were, round an axis, which axis is sometimes stationary, and at other times moves on in a particular direction. This phenomenon, called a whirl-wind, gives a whirling motion to dust, sand, water, part of a cloud, and sometimes even to bodies of great weight and bulk; carrying them either upwards or downwards, and lastly, scattering them about in different directions.

There are divers sorts of whirl-winds, distinguished by their peculiar names: as, the *prester*, *typho*, *turbo*, *exhydria*, and *cenephias*.

The *prester* is a violent wind breaking forth with flashes of lightning. This is rarely observed; scarcely ever without the *ecnephas*. Seneca says, it is a *typho*, or *turbo*, kindled or ignited in the air.

The *ecnephas* is a sudden and impetuous wind, breaking out of some cloud; frequent in the Ethiopic sea, particularly about the Cape of Good Hope. The seamen call them *travados*.

The *exhydria* is a wind bursting out of a cloud, with a great quantity of water. This only seems to differ, in degree, from the *ecnephas*, which is frequently attended with showers.

A *typho*, or *vortex*, most properly called a *whirl-wind*, or *hurricane*, is an impetuous wind, turning rapidly every way, and sweeping all round the place. It frequently descends from on high. The Indians call it *orancan*; the Turks, &c. *oliphant*. It is frequent in the Eastern ocean, chiefly about Siam, China, &c. and renders the navigation of those parts exceedingly dangerous.

Dr. Franklin, in his Physical and Meteorological Observations, read to the Royal Society in 1756, supposes a whirl-wind and a water-spout to proceed from the same cause; their only difference being, that the latter passes over the water and the former over the land. This opinion is corroborated by the observations of M. de la Pryme, and many others, who have remarked the appearances and effects of both to be the same. They have both a progressive as well as a circular motion; they generally rise after calms and great heats, and occur most frequently in the warmer latitudes: the wind blows every way from a large surrounding space both to the water-spout and whirl-wind; and a water-spout has, by its progressive motion, passed from the sea to the land, and produced all the phenomena and effects of a whirl-wind: so that there is no reason to doubt their being meteors arising from the same general cause, and explicable upon the same principles, furnished by electrical experiments and discoveries. See HURRICANE, and WATER-SPOUT.

For Dr. Franklin's ingenious method of accounting for both these phenomena, see his Letters and Papers, &c. vol. i. p. 191, &c. p. 216, &c.

WHISKET, or WISKET, in *Rural Economy*, a term often used provincially to signify a basket, especially in the northern counties. See BASKET.

WHISKY, a term signifying *water*, and applied in the Highlands and islands of Scotland and in Ireland to strong water or distilled liquor. The spirit drank in the North is drawn from barley, and is said to be preferable to any English malt-brandy: it is strong, but not pungent, and free from the empyreumatic taste or smell.

WHISPERING. See HEARING, ATTENTION, &c.

WHISPERING-Places, such as *domes* and *galleries*, depend on this principle, that the voice being applied to one end of an arch, easily passes by repeated reflections to the other.

Thus, let A B C (*Plate XV. Pneumatics, fig. 8.*) represent the segment of a sphere; and suppose a low voice uttered at D, the vibrations extending themselves every way, some of them will impinge upon the points E, E, &c. and thence be reflected to the points F, F, &c. thence to G, G, &c. till at last they meet in C; where, by their union, they cause a much stronger sound than in any part of the segment whatever, even at D the point whence they first proceeded.

Accordingly, all the contrivance in a whispering-place is, that near the person who whispers there be a smooth wall, arched either cylindrically, or elliptically; in which case he

will be heard distinctly by another person, who places his ear pretty near the wall on the opposite side. A circular arch will do, but not so well. It is demonstrated by all the writers on CONICS (which see), that if from any point in the circumference of an ellipse two lines be drawn to the foci, those lines make equal angles with one curve at that point. Consequently, the sound which is produced in one focus of an elliptical chamber, and is reflected from the wall to the other focus, makes all the angles of incidence equal to the angles of reflection respectively. Hence that focus is the place where the sound is best heard.

Places famed for the conveyance of whispers are, the prison of Dionysius at Syracuse, which increased a soft whisper to a loud noise; the clap of one's hand to the sound of a cannon, &c.; the aqueducts of Claudius, which carried a voice sixteen miles; and divers others enumerated by Kircher in his *Pinururgia*.

The most considerable in England are, the dome of St. Paul's, London, where the ticking of a watch may be heard from side to side; and a very easy whisper be sent all round the dome: this Dr. Derham found to hold not only in the gallery below, but above upon the scaffold, where a whisper would be carried over one's head round the top of the arch, though there be a large opening in the middle of it into the upper part of the dome: and the famous whispering-place in Gloucester cathedral, which is no other than a gallery at the east end of the choir, leading from one side of it to the other. It consists of five angles and six sides, the middlemost of which is a naked window; yet two whisperers there hear each other at the distance of twenty-five yards. See Birch's *Hist. of the Royal Society*, vol. i. p. 120. See ECHO.

WHIST, or WHISK, a well-known game at cards. Mr. T. Matthews, one of the last and most approved writers on the game of whist, has published (1816) a tenth edition of his "Advice to the Young Whist Player, &c." in which he has comprised, under the detail of 108 maxims, such instructions as are necessary to be observed by those who wish to play this game with skill and success. It would far exceed our limits, if we attempted to follow him in this detail; and an abridgment, if it were practicable, would be of little use; nor indeed is it necessary, as those who are desirous of acquiring a knowledge of the minutiae of the game will consult the author, whose "Advice" may be easily and cheaply procured. We shall, however, select some of those instructions that are the most important, and subjoin those laws of the game that serve to prevent or settle disputes among players.

The following maxims comprehend those instructions that relate to leads, to which we have annexed some other directions that are immediately connected with them. It is highly necessary, says Mr. M., to be correct in leads. When a good player plays an eight, and then a seven, it may be known that he leads from a weak hand; and the contrary, when he plays the seven first: the case is the same with a tray or a deuce.

Good players never lead a nine or ten, but for one of these reasons:

- 1st. From a sequence up to the king.
- 2d. From nine, ten, knave, and king.
- 3d. When the best of a weak suit not exceeding three in number.

1. The safest leads are those that are furnished by sequences of three or more cards; in which case the player is advised to lead the highest, and to put on the lowest to his partner's lead, and to put the highest on his adversary's; and with a tierce to the king and several others, to begin with

with the knave. If he has no sequences, he is instructed to lead from his most numerous suit; if strong in trumps, to lead rather from one headed by a king than a queen; but with three or four small trumps, Mr. Matthews prefers leading from a single card to a long weak suit. But the players of the old school never lead from a single card without six trumps. In some cases, Mr. M. observes, this may be occasionally done with very great, though not certain, advantage; *e. g.* when A has four small trumps, ace, queen, &c. of the second suit; king, knave, &c. of a third; and a single card of the fourth. To lead from three cards, unless in sequences, is bad play, and only proper when you have reason to think it is your partner's suit, and then lead off the highest. Unless, says Mr. M., you have a strong suit yourself, or have reason to suppose that your partner has one, do not trump out unless you have six trumps. It is generally right to return your partner's lead in trumps, unless he leads a nine or ten, called an equivocal card, because it is led with propriety, both from strong and weak suits.

2. With ace, king, knave, and three small trumps, play the ace and king; with only two, the king, and wait for the finesse of the knave. In other suits, without great strength in trumps, or with the hopes of a particular point, do not wait for the finesse.

3. Ace, king, and five others, lead the ace in all suits. With four or less, the lowest, if trumps. In other suits always the ace, unless all the trumps remaining are with you and your partner; in this case, a small one.

Mr. M. advises not to lead trumps merely because an honour is turned up on your left, nor to be deterred from it if on your right-hand; either, he says, is proper, if the circumstances of your hand require trumps to be led; but neither otherwise.

It is equally advantageous to lead up to an ace as through an ace; not so much so to a king, and disadvantageous to the queen turned up.

When cards are nearly equal, says this author, the point to which all the manoeuvres of good whist players tend, is to establish a long suit, and to preserve the last trump, to bring it into play, and to frustrate the same play of their adversaries. With an honour (or even a ten), with three other trumps, by well managing them, you have a right to expect success. In this case, do not over-trump your right-hand adversary early in the hand; but throw away a losing card, by which, there remaining but twelve trumps, your own hand is strengthened, and your partner has the tenace, in any suit that is led; whereas, had you over-ruffed, you would have given up the whole game, to secure one trick. But there are reasons for breaking this rule:—1st. If your left-hand adversary has shewn a decided great hand in trumps, (in which case make your tricks while you can,) or 2d. If your partner decidedly means to force you,—to understand if this is the case, you are to observe, if your partner plays the winning or losing card of the suit you have refused. If the former, it is by no means clear he means to force you, and you play your own game. If the latter, you are to suppose him strong in trumps, and depend on this, to protect your long suit: a due reflection on this will convince you of the value of that maxim, which enjoins you never to play a strong game with a weak hand, or *vice versa*.

It is difficult to judge when to lead trumps. The following situations will assist the beginner to reason, and in general direct him properly:

1st. With six trumps, on supposition your partner has a strong suit.

2d. If strong in other suits, though weak in trumps yourself.

3d. If your adversaries are playing from weak suits.

4th. If your adversaries are at the point of eight, and you have no honour, or probability of making a trump by a ruff.

With king, queen, ten, &c. in all suits, lead the king; but if it passes, do not pursue the lead, as certain the ace is in your partner's hand, as it is often kept up, but change your lead, and wait for the return from your partner when you have the finesse of the ten, if necessary.

King, queen, and five others, in all suits, the king. With four or less in trumps, lead the lowest. In other suits, always the king, unless you have the two only remaining trumps, if so you may play a small one.

King, knave, ten, &c. in all suits, lead the ten. King, knave, and two or more small ones, the lowest.

You should not lead from king, knave, and a small one, unless it is clearly your partner's suit, in which cases play off your king and knave.

Queen, knave, nine, and others, lead the queen. Queen, knave, with one other, the queen. Queen, knave, with two more, the lowest. Queen, ten, and two others, the lowest. Queen, and three small ones, the lowest. Queen, or knave, with only two, the queen, or knave.

The trump card sometimes occasions a deviation from these rules. A has the ace or king, with sequence from the ten downwards, of the suit of which his left-hand adversary turns up knave, or queen—A should lead the ten. If the knave or queen be put on, you have a finesse on the return with the nine; if not, your partner, with an honour, will pass it, and it is either way advantageous.

That which is denominated under-play, is returning the lowest of your left-hand adversary's lead, though you have the highest in your hand, with a view of your partner's making the third best, if he has it, and still retaining the commanding card in your hand.

To explain this further, suppose A fourth player, has ace and king of his left-hand adversary's lead; to under-play, he wins the trick with the ace, and returns the small one, which will generally succeed, if the leader has not the second and third in his own hand. You will see by this, if you lead from a king, &c. and your right-hand adversary, after winning with a ten or knave, return it, you have no chance to make your king, but by putting it on.

The following is another situation to under-play; A remains with the first, third, and fourth cards of a suit, of which he has reason to suppose his left-hand adversary has the second guarded; by playing the fourth, it is often passed, and A makes every trick in the suit.

When it is at your option to be 8 or 9, it is material always to choose the former score. When at eight, with two honours, look at your adversary's score, and consider if there is a probability they should save their lurch, or win the game, notwithstanding your partner holds a third honour; if not you should not call, as it gives a decided advantage against you in playing for tricks.

Laws of Whist.—1. If a card is turned up in dealing, the adverse party on naming it may call a new deal, unless they have looked at or touched the cards, so as to have occasioned it; but if any card except the last is faced, it is undoubtedly a new deal.

2. Should any card-player have but twelve cards, and the others their proper number, the deal is good, and he who has the twelve cards pays for any renounce he may have

have made; but if either have fourteen cards, the deal is lost.

3. If the dealer does not turn up the last card, the deal is lost. But if the card is shewn, and falls on its face by accident afterwards, the deal in this case shall stand good.

4. The dealer should leave the last card on the table till he has played; after which nobody can ask for it, though they may inquire what is trumps at any time. Should he leave it on the table after the first round, it may be called, as if shewn by accident.

5. Every person has a right before he plays to call on the players to place their cards before them, which is, in other words, to ask who played them. It is therefore a quibble to say they have no right to make that demand.

6. The partner who reminds his partner to call after the trump is turned up, forfeits a point.

7. If one of the players omit playing to a trick, and remains with a card too many, it is at the option of the adversaries to call a new deal.

8. If A plays out of his turn to his partner's lead, the last player may play before the first: if to his adversary's, his partner may be compelled to, or prevented from winning the trick at their option.

9. Mistakes relative to tricks may be rectified at any time during the game, whether called or not. Also honours, if proved to have been called in time, though not scored; but they cannot be claimed after the trump is turned up.

10. If one party calls at any score but eight, the adversaries may, after consulting, call a new deal; the same, if one calls without two, or the other answers without one honour.

11. If any player calls after he has played, the adversaries may call a new deal; but not consult together.

12. Whoever calls, having only one honour in his hand, should forfeit in proportion to any advantage that actually does or may possibly accrue from the fault. If it should prevent the adversaries from calling, after the hand is played out, the honours shall take place of the tricks.

13. If any person plays out of his turn, the adversaries have the option to call that card at any time, or direct the player whose turn it was, to play any suit they choose.

14. If A, supposing that he has won a trick, leads again before his partner has played to it, the adversaries may oblige his partner to win it, if he can.

15. Any player may call a card from his adversary, if he names it, and proves the separation. Should he name a wrong one, he may have his best or worst card called of any suit played during the deal.

16. Cards thrown down cannot be taken up again; but may be called by the adversaries. They may be shewn down by the player, if sure of every trick.

17. There are in fact four penalties on a revoke, which take place of every other score. The adversaries may take three tricks from the party revoking, or three from their score, or add three to their own; and if there still should remain enough to make the party revoking game, they cannot win it, but remain at nine.

There is often judgment required in taking the penalties of a revoke. Before the score is advanced, if the party revoking has won nine tricks, the least consideration will shew, that the adversaries should take three of them, for if they add three to their own score, they still leave the odd trick to the

former; but if the revoking party be at eight, it is better for the adversary to score three points, as the odd trick leaves the former at nine, which is in every respect a worse point than eight. On other occasions, it is only to calculate how the different scores will remain after each mode of taking the penalty; and it will be obvious which will be the most advantageous—never losing sight of the points of the game; *i. e.* scoring eight or five yourself, or prevent your adversary from doing so.

18. A revoke is not established before the party revoking has played again, or the trick been turned and quitted; but the adversaries, at their option, may call from the highest or lowest of the suit at the time, or the card shewn at any time during the deal.

19. If a revoke is claimed, the adversaries forfeit the penalties of a revoke, if they mix the cards before it is determined.

20. No revoke can be claimed after the cards are cut for the next deal.

21. A case having occurred in which A played out of his turn, and B, his partner, was directed to play a trump; but B had another suit, and three or four cards were played before it was discovered that B had a trump in his hand: it was decided, that the cards should be taken up again, and a trump led by B as directed.

22. A case occurred in which A called at eight, but his partner did not answer, though he had an honour, because he had a bet on the odd trick. The adversaries contended that the deal should not stand; and reference being made to Mr. M., he decided that the game was fairly won, because there could be no possible advantage made of the circumstance as far as related to the game, though it might as to the trick, if that had been the case referred; and their case produced the following law: *viz.* No one is obliged to answer to his partner's call, even though he has the other two honours in his hand.

23. No player, having three honours in his hand, can be precluded from taking advantage of them at any time previous to his playing a card. This law was grounded on the following case; *viz.* A at the score of eight, on gradually opening his hand, saw two honours in it immediately, and told his partner of it, who did not answer: but A continuing to look over his cards found a third honour, and shewed them down. It was contended that he had no right to do this, as Mr. M. thought improperly, upon which he proposed the above-mentioned law. We here subjoin a maxim connected with this case.

When at eight, with two honours, look at your adversary's score, and consider if there is a probability they should save their lurch, or win the game, notwithstanding your partner holds a third honour; if not you should not call, as it gives a decided advantage against you in playing for tricks.

24. Whoever shall by word or gesture manifestly discover his approval or disapprobation of his partner's mode of play, or ask any questions but such as are specifically allowed by the existing laws of whist, the adversary shall either add a point to his own score, or deduct one from the party so transgressing, at his option.

25. It is now settled, that either of the players may insist on the cards being placed at any time previous to their being put together. It is also settled, that where a bet is made, that either of the parties scores two, the bet is won by honours, though the adversary has won the game by cards—supposing it betted that A makes two points, if B, his

his adversary, being at seven, makes three by cards, if A has two by honours, he still wins his bet.

The odds of this game are calculated according to the points, and with the deal, in the following manner :

- 1 love - - 10 to 9
- 2 love - - 10 to 8
- &c. &c.

Except that 9 is considered as something worse than 8. It is 3 to 1 in favour of the first game. The odd trick has been always supposed in favour of the leader ; but Mr. M. is of opinion, that this is an error, as the dealer has the advantage in this, as in every other score.

We shall here subjoin an explanation of two terms that are universally used, but not generally understood, viz. *tenace* and *finesse*.

“The principle of the *tenace* is simple. If A has the ace and queen of a suit, and B, his adversary, has the king and knave, the least consideration will shew that if A leads, B wins a trick, and *vice versa* of course ; in every situation it is the mutual plan of players by leading a losing card to put it into the adversary’s hand to oblige him to lead that suit, whereby you preserve the *tenace*. So far is easily comprehended ; but it requires attention with practice to apply the principle, so obvious in the superior, to the inferior cards, or see that the same *tenace* operates occasionally with the seven and five, as the ace and queen, and is productive of the same advantage. A, last player, remains with the ace and queen of a suit not played, the last trump, and a losing card ; B, his left-hand adversary, leads a forcing card. *Query*—How is A to play ? *Answer*—If three tricks win the game, or any particular point, he is not to ruff, but throw away his losing card, because his left-hand adversary being then obliged to lead to his suit, he remains *tenace*, and must make his ace and queen. But upon a supposition that making the four tricks gains him the rubber, he should then take the force, as in these situations you are justified in giving up the *tenace* for an equal chance of making any material point.

“The *finesse* has a near affinity to the *tenace*, except that the latter is equally the object where two, and the former only where there are four players. A has the ace and queen of a suit led by his partner, now the dullest beginner will see it proper to put on the queen ; and this is called *finessing* it, and the intention is obviously to prevent the king from making, if in the hand of his right-hand adversary. Should it not be there, it is evident you neither gain nor lose by making the *finesse* ; but few players carry this idea down to the inferior cards, or see that a trick might be made by a judicious *finesse*, against an eight, as a king ; but to know exactly when this should be done, requires more skill than in the more obvious cases, united with memory and observation. Another case of *finesse* even against two cards frequently occurs, and the reason on reflection is self-evident.

“A leads the ten of a suit, of which his partner has the ace, knave, and a small one ; B should *finesse* or let the ten pass, even though he knows the king or queen are in his left-hand adversary’s hand, because he preserves the *tenace* and probably makes two tricks ; whereas, had he put on his ace, he could make but one—in short, *tenace* is the game of position, and *finesse*, the art of placing yourself in the most advantageous one.” Matthews’s Advice, &c. ed. 10. 1816.

M. de Moivre has solved this problem : To find the odds that any two of the partners, that are pitched upon, have not the four honours ? M. de Moivre concludes from this solution,

1. That it is 27 to 2, nearly, that the dealers have not the four honours.
2. That it is 23 to 1, nearly, that the eldest have not the four honours.
3. That it is 8 to 1, nearly, that neither one side nor the other have the four honours.
4. That it is 13 to 7, nearly, that the two dealers do not reckon honours.
5. That it is 20 to 7, nearly, that the two eldest do not reckon honours.
6. That it is 25 to 16, nearly, that either one side or the other do reckon honours, or that the honours are not equally divided.

The same learned author also determines, that the odds for the partners who have eight of the game, if dealers, against those who have nine, is nearly as 17 to 11. But if those who have eight of the game are eldest, the odds will be nearly as 95 to 77. And that without considering whether those who have eight are dealers, or eldest, there is one time with another the odds of somewhat less than 7 to 5 ; and very nearly that of 25 to 18.

It is a question likewise belonging to this game, what the probability is that a player has a given number of trumps dealt him ; particularly, it has been often taken as an equal wager, that the dealer has at least four trumps. M. de Moivre has computed the following tables ; shewing for the dealer, as well as the other gamblers, what the probability is of taking precisely any assigned number of trumps in one deal. And thence by a continual addition of the numbers, or of such part of them as is necessary, it is easily found what the probability is of taking at least that number.

Chances of the Dealer to have besides the Card turned up.	Trumps.	Chances of any other Gambler to have precisely.

Sum = 158753389900		476260169700 = sum,
is the common denominator ; being the combinations of 12 cards in 51.		is the common denominator ; being the combinations of 13 in 51.

By the help of these tables several useful questions may be resolved ; as, 1. If it is asked, what is the probability that the dealer has precisely III trumps, besides the trump card ? The answer, by Table I., is $\frac{4662}{15875}$; and the probability of his having some other number of trumps is

$\frac{11213}{15875}$. But if the question had been, what is the probability that some other gamester, the eldest hand for instance, has precisely IV trumps? The answer, Table II., is $\frac{104898}{476260}$.

2. To find the chance of the dealer's not having fewer than IV trumps: add his chances to take 0, I, II, which are 39108, 201127, 419592; and their sum 659827 taken from the denominator 1587534, and the remainder made its numerator, the probability of the dealer having IV or more trumps will be $\frac{927707}{1587534} = \frac{329}{563}$, a little above

$\frac{7}{12}$. The wager, therefore, that the dealer has not IV trumps, is so far from equal, that whoever lays it throws away above $\frac{1}{5}$ of his stake.

But if the wager is, that the dealer has not V trumps; then 466213 (the chances of his having III besides the trump card) is to be added to the chances for 0, I, II; which will make the chance of him who lays this wager to be nearly $\frac{317}{455}$; and that of his adversary $\frac{138}{455}$.

And hence, if wagers are laid that the dealer has not IV trumps, and has not V trumps, alternately; the advantage of him who lays in this manner will be nearly $11\frac{1}{2}$ per cent. of his stakes.

3. To find the odds of laying that the eldest hand has at least III, and at least IV trumps, alternately; the numerator of the one expectation is (by Table II.) 3150119, and of the other 17514720, to the denominator 47626017;

whence the advantage of the bet will be $\frac{15}{514}$, or three per cent. nearly.

Again, if it is laid that the trumps in the dealer's hand shall be either I, II, III, or VI; the disadvantage of this bet will be only 15s. 4d. or about $\frac{3}{4}$ per cent.

In like manner, the odds of any proposed bet of this kind may be computed: and from the numbers in the tables, and their combinations, different bets may be found which shall approach to the ratio of equality; or if they differ from it, other bets may be assigned, which, repeated a certain number of times, shall balance that difference.

4. And if the bet includes any other condition besides the number of trumps, such as the quality of one or more of them; then proper regard is to be had to that restriction.

Let the wager be that the eldest has IV trumps dealt him; and that two of them shall be the ace and king. The probability of his having IV trumps precisely is, by

Table II., $\frac{104898}{476260}$: and the different fours in 12 cards

are $\frac{12}{1} \times \frac{11}{2} \times \frac{10}{3} \times \frac{9}{4}$. But because 2 out of the 12 trumps are specified, all the combinations of 4 in 12 that are favourable to the wager, are reduced to the different two that are found in the remaining 10 cards, which

are $\frac{10}{3} \times \frac{9}{2}$. And this number is to the former as 1 to 11: the probability, therefore, is reduced by this restriction to $\frac{1}{11}$, of what else it had been: that is, it is re-

duced from near $\frac{1}{5}$ to about $\frac{1}{52}$. De Moivre's Doctrine of Chances, p. 172, &c. ed. 3d.

WHISTLE, BOATSWAIN'S. See CALL.

WHISTLE-Fish, a name given by the people of Cornwall to a species of gadus, with only two fins on the back, otherwise called *mustela fluviatilis*. See GADUS, and MUSTELA.

WHISTON, WILLIAM, M.A. in *Biography*, an English divine and mathematician, was the son of the rector of Norton near Twycrofs, in Leicestershire, and born in the year 1667. He finished his education as a sizer at Clare-hall, Cambridge, applying with great diligence to the study of mathematics, and composing devout meditations corresponding to the early bent of his disposition. Having also received the degree of B.A. in 1690, and being elected fellow of his college, he took pupils; and in 1693 became M.A. and entered into holy orders. Soon afterwards he declined the office of tutor, and was appointed chaplain to Dr. More, bishop of Norwich. His acquaintance with sir Isaac Newton commenced in 1694, and produced a change in his philosophical system, from that of Des Cartes to that of Newton. On the principles of this philosophy, he published, in 1696, his "Theory of the Earth," which was refuted by Keill. Having been presented by his patron, the bishop, to the living of Lowestoft in Suffolk, he resigned his chaplainship, and in order fully to discharge his religious duties procured the assistance of a curate. Of his invincible and moral scrupulous integrity, he gave an early instance by refusing his vote to a person who solicited a fellowship of Clare-hall, and who had abandoned the bacchanalian party with which he was connected, and which he apprehended to be the most powerful, and promised future sobriety; and giving this reason for his refusal: "Sir, you have confessed that you sacrificed your integrity to your preferment, and thereby have made it impossible for me to serve you." Being obliged to vacate his fellowship by marriage, sir Isaac Newton nominated him his deputy as professor of mathematics, allowing him all the profits of the office; and in 1703 he surrendered to him the professorship itself. Upon this accession, he resigned his living, settled at Cambridge, and was appointed by Dr. More, bishop of Ely, catechetical lecturer of St. Clement's. Having already published "A Short View of the Chronology of the Old Testament, and the Harmony of the Four Evangelists," and "Tacquet's Euclid," he presented to the public in 1706 his "Essay on the Revelation of St. John;" and in the following year he preached the Boyle's lecture sermon on the subject of the "Accomplishment of Scripture Prophecies." In the year 1706 he began to entertain doubts concerning the divinity of Christ, and in the prosecution of his inquiries he was led to adopt Arian opinions, which were further confirmed by the perusal of the "Apostolical Constitutions," reckoned spurious by most writers, but pronounced by Whiston to be "the most sacred of the canonical books of the New Testament." In 1708 he offered an "Essay on the Apostolical Constitutions" to be printed at the University press, but it was rejected; however, in 1709, he published sermons and essays supporting these opinions. His invincible perseverance caused him to be deprived

deprived of the catechetical lecture, and at the same time he declined receiving the salary which the bishop wished to continue. His situation at the University became very precarious, and in October 1710 he was expelled from it, in conformity to a statute against maintaining doctrines contrary to the established religion. In the following year he also lost his professorship; and having no further employment at Cambridge, he removed to London, and published an account of the proceedings against him, and also books in defence of his sentiments, which he retained without regarding any worldly considerations. His purposes were fixed, and he declared to two friends, who wished him to pay some attention to his present welfare, "you may as well persuade the sun to come down from the firmament, as turn me from this my resolution." Hoadly and Clarke remonstrated; but all their pleas were unavailing. All his future prospects seemed now to depend on his knowledge of mathematics, and accordingly in 1710 he published his "Prælectiones Physicæ-Mathematicæ; five Philosophiæ Clarissimi Newtoni Mathematica illustrata." At this time Addison and Steele, and several other persons, exerted themselves in procuring a subscription to his astronomical lectures. But at the close of this year he published the "Historical Preface" to a proposed work on Primitive Christianity, which subjected him to the inquisitorial animadversion of the lower house of convocation. Escaping, however, the apprehended consequences of their interference, he persisted in his course, and in 1711 printed this work which he had announced, and which had occasioned an alarm, in 4 vols. 8vo. The convocation, not sufficiently informed with regard to the extent of their power in cases of heresy, addressed the queen in order to obtain the opinion of the judges, who disagreed upon the subject, and no further measures were pursued by this body. However, in 1713, Whiston was prosecuted in the spiritual court; and as he did not appear to its citation, he was declared contumacious. Difficulties occurring on the part of the lay-judges, the business was deferred, and the prosecution was terminated by an act of grace in 1715. Whiston was at this time a professed member of the established church, and attended its worship, till at length he was refused admission to the sacrament; and therefore he opened an assembly for worship at his own house, and used a liturgy of his own composing. He also established a weekly meeting for the promotion of primitive Christianity, which subsisted for two years. Whilst he was thus occasionally engaged, he devoted himself to mathematical and philosophical pursuits; and in concert with Mr. Ditton, who was his colleague in his lectures, published a project for discovering the longitude at sea. But as their speculations were of no use, it will be sufficient to observe, that he published at last a method of ascertaining the longitude by observations of the eclipses of Jupiter's satellites, with tables of such eclipses for four years from the year 1738.

His zeal in religious discussions and projects remained unabated; and, among other publications in 1716 and the two following years, appeared several pieces founded on the supposed genuineness and authority of the apostolical constitutions. In 1719 he published a letter addressed to Finch, earl of Nottingham, on the "Eternity of the Son of God and his Holy Spirit," which received an answer from his lordship, that induced the clergy and universities to return him public thanks, and which caused Whiston's exclusion from the Royal Society, when he was proposed as a candidate in 1720. Sir Isaac Newton, it is said, who was of a very timid temper, took measures for defeating his election. As he was of opinion

that the Jews would be speedily restored to their native land, he procured models of the tabernacle of Moses and the temple of Jerusalem, upon which he read public lectures. In 1741 he undertook a survey of the coasts of England, in order to fix the longitude of places, and a chart to this purpose was published in 1745. It was in the year 1747 that he discontinued his attendance on the service of the church of England, and joined a Baptist church, in which connection he continued. In 1749 he published two volumes of memoirs of his own life, to which a third was added in 1750. Having attained to the 85th year of his age, he died at London in 1752, and was interred at Lyndon, where his daughter was married, and where a handsome tomb was erected in honour of his memory. "Fancy," says one of his biographers, "predominating over judgment, a warm head and honest heart, enthusiastic fervour, and disregard to common forms and worldly consequences, were the leading features of his character." He never hesitated in giving his opinion to all persons on all subjects, freely and without discrimination. Being once asked, in the presence of Addison, Pope, Walpole, Craggs, and others, "whether a secretary of state could be an honest man consistently with the duties of his station?" He gave his opinion that it would be of advantage to such an officer to speak openly what he knew, and declare his intentions without disguise. Mr. Craggs replied, "It might answer for a fortnight, but no longer." "Did you never, Mr. Secretary," returned Whiston, "try it for a fortnight?" When queen Caroline, who honoured Whiston's integrity, and was fond of his conversation, desired him to acquaint her what was particularly found fault with by censurers on her conduct; he replied, that her habit of talking at chapel was mentioned with disapprobation. She promised amendment, and wished him to point out any other faults. "When your majesty," said he, "has amended this, I will tell you of the next." A catalogue is given of Whiston's writings, which are very numerous, at the close of his "Memoirs of Dr. Clarke." He has also given a valuable "English Translation of Josephus," with plans, notes, and illustrations, to which are prefixed eight dissertations. Biog. Brit. Memoirs of his Own Life.

WHITAKER, JOHN, B.D. a divine of the established church, was born at Manchester, about the year 1735, and educated at Oxford, where he became fellow of Corpus-Christi college, taking the degree of M.A. in 1759, and of B.D. in 1767. His first work, viz. "The History of Manchester," appeared in 1771, 4to., in which he takes occasion to give a view of the state of the kingdom in general. This work, abounding in literary research and ingenious conjecture, gave reputation to the writer, and was followed in the same year by "The Genuine History of the Britons asserted." However, it is said that Mr. Whitaker's imagination in the progress of his years misled his judgment, of which he gave evidence in the second volume of his "History of Manchester," printed in 1775, though he still maintained his character for deep and learned investigation. As a clergyman, he became morning-preacher of Berkeley chapel, London, in 1773, from which situation he was soon after removed; and he resented his removal with the natural warmth of his temper. Such was his orthodoxy, that he declined accepting a valuable living that was offered to him by an Unitarian patron. In 1778 he succeeded, as fellow of his college, to the rectory of Ruan-Lanyhorne in Cornwall, where his contest about tithes was the occasion of much uneasiness to him. When mutual conciliation took place between him and his parishioners, he published in 1783 a course of Sermons on Death, Judgment, Heaven,

and Hell, which were rendered peculiarly impressive by the fervid eloquence with which he treated the subject, naturally awful and interesting. In 1787 he published his "Mary Queen of Scots vindicated," 3 vols. 8vo., in which he surpassed former writers in the zeal with which he vindicated this unfortunate queen, and crminated her enemies, Elizabeth, Cecil, Morton, and Murray. He also presented to the public the fruit of his learned research in "The Course of Hannibal over the Alps ascertained," 2 vols. 8vo. 1794; and in 1795 he advanced the highest monarchical principles in his work, entitled "The real Origin of Government," and also his orthodoxy in his "Origin of Arianism," zealously defending his sentiments in both these respects by contributions to the English and Jacobin Reviews, and British Critic. At length a paralytic stroke warned him of his approaching end, and after a gradual decline he imperceptibly closed life at his rectory in October 1808, at the age of 73, leaving a widow and two daughters. Gen. Biog.

WHITBREAD, SAMUEL, an eminent brewer, claims a place in a work devoted to the record and promotion of the arts and sciences, on account of the talents which he displayed and the character which he maintained in his advancement from small beginnings, to the possession of a fortune, that set him on a level with some of the first nobility of the country. The family from which he sprung belonged to the class of yeomanry, in the county of Bedford, which possessed some small property, and associated with that description of moderate dissenters, who occasionally conformed to the Church of England. Born in the village of Cardington near Bedford, about the year 1720, and educated probably with a view to trade, for which his family designed him, he was bound apprentice at a suitable age, for the term of seven years, to an opulent brewer in London; and after the expiration of that period, he remained for some time unsettled, as he was cautious in commencing business on his own account. At length, however, actuated by the laudable ambition of tracing the footsteps of those who, in a similar department, had risen to opulence and rank, he determined to make trial for himself, how far industry and activity, aided by economy, would avail to his success. Having disposed of his own patrimony, which could not have been very considerable, and deriving assistance from persons of opulence, who were encouraged to repose confidence in him by his known disposition and habits, he laid the foundation of a superstructure of fortune and reputation, which has had few parallels in the history of commerce. Simple in his manners, he was accustomed to appear at the corn-market in Mark-lane with a white apron, as the emblem of his occupation; and liberal in his disposition, he contrived to secure the attachment and active services of those with whom he was connected in his domestic arrangements, and in the conduct of his business. He well knew that by making those whom he employed partakers of his bounty, he gave them a kind of interest in his prosperity; and therefore on settling the annual balance of his accounts, he distributed amongst them donations, corresponding to their respective ranks and services. Whilst he gave 500*l.* to a confidential clerk, he extended his bounty even to the horse-feeders, to each of whom he usually gave 5*l.*

Advancing with sure, but rapid progress, his brew-house in Chifwell-street became a spacious quadrangle, consisting of an ample dwelling-house, work-houses, stoves, cellars, and every other kind of convenience both for habitation and business; while the stock, the plant, the dray-horses that would have mounted a regiment of cavalry, the casks, &c. might in process of time be estimated at nearly half a mil-

lion of pounds sterling. To this immense property, we might add a floating capital amounting to from 80 to 100,000*l.* serving to supply the demand of malt, hops, oats, &c. as well as the payment of clerks and servants. Thus by the direction and superintendance of a single individual, with the co-operation of a number of coadjutors in various ranks of subordination, the brew-house in Chifwell-street became the first establishment of the kind, not only in London, but in Europe, depending for its subsistence and singular prosperity on the approved quality of the article which it furnished. To the founder and principal proprietor, it became a mine of wealth, and an immense source of supply for purchases of land and houses, donations and bequests, that have given distinguished celebrity to the name of Whitbread. It is needless to recount the various estates which he purchased in his native county; we shall content ourselves with mentioning merely the Torrington manors and estates, for which he paid the sum of 120,000*l.*, besides 5000*l.* as a present to alderman Skinner the auctioneer, when the negotiation respecting it was completed. Of his benefactions and bequests to various objects of public utility and of private charity, it will be sufficient to say, that they indicated the liberality of his disposition, and the amplitude of the means which he derived from his singular prosperity. Mr. Whitbread was twice married; by his first wife he had several children: but his second wife, who was daughter of the first earl, and sister of the first marquis Cornwallis, and to whom he was married August 12, 1769, died December 27, 1770. He was for some years one of the representatives of the town of Bedford, and afterwards returned for the borough of Steyning. For the abolition of the slave-trade, he was a steady and ardent advocate; and as such he generously undertook from his private purse to make good all injuries that might be suffered by those who attended to give their testimony for this purpose. With this expression of benevolence he closed a life, during the progress of which he had amassed landed and chattel property to an immense amount, without any of those penurious habits, which have been in many instances the means of accumulating large fortunes, and of enabling those to die rich who have lived meanly and miserably. His death happened June 11th, 1796.

In 1799 his son, the subject of the next article, erected a splendid monument to his father's memory, in the church of Cardington; which monument was the last, and has been thought by some persons to be the best work of the late J. Bacon, R.A. The principal figure represents a dying man, supported by religion, in the form of a female, who points to the glory of heaven as a reward for his good actions; while the figure of benevolence, in a reclining posture, is weeping at his feet.

WHITBREAD, SAMUEL, a distinguished senator, was the son of the preceding by his first wife, and born in the year 1758. Destined to the inheritance of a large fortune, and possessing talents which by due cultivation would qualify him for a conspicuous station in public life, his father spared no expence in his education. At a proper age he was sent to Eton, where he also enjoyed the benefit of private tuition, and where he commenced an intimate acquaintance with Mr. W. H. Lambton, afterwards M.P. for the city of Durham, and Mr. now earl Grey, with whose family he became connected by a double alliance. From Eton he removed to Christchurch college, Oxford, and from thence to St. John's college, Cambridge, where he finished his education, and was graduated B. A. Mr. Whitbread senior, sagacious in discerning the early dawning of his son's future celebrity, liberally offered him all the advantages which might
be

be derived from foreign travel, and selected for his tutor and companion the present archdeacon Coxe, well known by a variety of valuable publications. Having travelled together through France, Germany, and Switzerland, they afterwards separated with professions of mutual regard. Mr. Whitbread, soon after his return, formed, in 1788, a matrimonial connection with Miss Grey, the sister of his Eton associate, who afterwards, by the advancement of her father, general sir Charles Grey, to an earldom, became lady Elizabeth Whitbread: his sister also, in process of time, married the present sir George Grey, bart. then a captain in the navy. Having acquired every necessary qualification for occupying a seat in the great council of the nation, and interested by an ample fortune either in possession or in prospect, as well as by genuine sentiments of patriotism, in its deliberations and resolutions, Mr. Whitbread offered himself, on the dissolution of parliament in 1790, as a candidate for Bedford, a borough which had been represented by his father, who at the same time offered himself for the borough of Steyning. Both elections were contested; but both father and son finally obtained their respective seats. Mr. Whitbread, junior, commenced his political career in parliament with an animated speech against the unconstitutional doctrine of "confidence," assumed on the part of ministers, who claimed an entire reliance on their wisdom and integrity. The occasion of this claim was a proposed war against Russia, for which the minister (Mr. Pitt) urged the house of commons to vote money, without previous and satisfactory information of the necessity, and much less of the justice or policy of this war, the object of which was the restoration of Oczakow to the Turks. The measure was unpopular; and though the minister obtained a majority, when the question was debated, he thought it most prudent to give up his object, and a pacification ensued, which prevented much calamity to the nation. About this time the abolition of the slave-trade occupied the public attention, and this was a measure to which the member for Bedford had always avowed himself a steady and zealous friend. In parliament he supported it not only by his vote, but by a display of eloquence which commanded universal applause. As an active magistrate, he directed his particular attention to the occurrences that took place in consequence of the scarcity in the year 1795; and in devising means of relief, he proposed that as the magistrates were empowered to fix a *maximum* of wages, so far as respects the husbandman, a *minimum* should be also preserved by law, in order thus to establish a more accurate proportion between the price of labour and that of the means of subsistence. With this view he introduced into the house a bill, which was approved by Mr. Fox and many other members; but as it was opposed by Mr. Pitt, his efforts were unavailing. The minister was no less unsuccessful in his plan for amending the poor laws, and meliorating the condition of the peasantry and working class. His plan indeed was much more extensive and complicated than that of Mr. Whitbread, which was simply calculated to enable the labourer to maintain himself by his wages, without the degrading as well as dispiriting necessity of seeking parochial relief.

The subject of this article was an undisguised and uniform opposer of the French war in 1793, because he thought it to be unnecessary and unjust; and yet he was a zealous advocate for measures of self-defence against the secret machinations and open attacks of a powerful and vindictive enemy. Accordingly he condemned the negligence of ministers, on occasion of the French attempt at invasion in 1797, by means of a squadron which appeared off Bantry bay, and moved the house for a committee of inquiry into

their conduct. His motion was evaded by the previous question. In every stage of the contest with France, and under every varying form of its government, he was anxious for peace, and an advocate for treating with its rulers in order to terminate hostilities, and to put a stop to the waste of national treasure and the effusion of human blood. His opinion on the conduct of ministers in the prosecution of this war, and their reluctance to enter into treaty for terminating it, was explicitly avowed in an eloquent speech, which he delivered on occasion of a motion by Mr. Dundas (then secretary of state) for an address to the throne in 1800, for the purpose of approving the conduct of his majesty's government. Anxious, however, as he was for peace, because he disapproved the war from its commencement, and because he thought it essential to the true interest of the country, he was no less solicitous to maintain the honour of the nation in obtaining it. No man in this respect was a more noble-minded patriot than himself; and if he consented to make any sacrifice, it was because he thought it absolutely necessary to the permanent prosperity of his native country. Whilst he claimed and exercised the privilege of pronouncing his own opinion of public men and political measures, he was a zealous advocate for the liberty of others, and interposed with his most vigorous exertions for the rescue of those who suffered imprisonment at home or exile to Botany bay, for too freely and imprudently divulging their opinions. During the short interval of the administration of Mr. Addington, (the present lord Sidmouth,) who succeeded Mr. Pitt in the year 1801, and made peace with Buonaparte, several popular measures were adopted, in which Mr. Whitbread cordially concurred; and in the year 1805 he distinguished himself as the public accuser of Mr. Dundas (created lord Melville) for malversations that had occurred, whilst he had occupied the post of treasurer of the navy. His charges against this nobleman were founded on a report of the commissioners of public accounts, from which it appeared that, during the exercise of his office, this noble lord had violated the law, by conniving at mal-practices and participating in unwarrantable emoluments; and that he was responsible for deficiencies amounting to 697,500*l.* These charges also implicated Mess. Trotter, Wilton, and Spratt; and the former in particular, who was paymaster of the navy department under lord Melville, and had taken out large sums of money on his own private account. In the investigation of this business, it was discovered, that the sums officially deposited in the Bank had been withdrawn, lodged with private bankers, and applied to other purposes besides those that were properly naval. Mr. Whitbread founded on several facts which he stated, a variety of resolutions which impeached the fidelity and honour of his lordship. To his motion relative to this business, Mr. Pitt moved an amendment, which was negatived by a majority of one (217 to 216), in consequence of the vote of the speaker. In consequence of these proceedings, the viscount resigned his office at the Admiralty-Board, and his name was expunged from the list of privy-counsellors. Upon the sudden demise of the premier, and a coalition between lord Grenville and Mr. Fox, the two latter came into office; and Mr. Erskine, being raised to the peerage, and appointed lord high chancellor, was destined to preside at lord Melville's trial. This nobleman having made his defence within the bar of the house of commons was replied to by the member for Bedford; and an impeachment being agreed upon, proceedings commenced in Westminster-hall, April 29th, 1806. The result, after a short trial, was the acquittal of his lordship by a majority, from all the charges alleged against him. Notwithstanding the unexpected termination of this trial, neither the

friends nor the enemies of the supposed delinquent attached any blame to the public accuser; but he was allowed to have conducted the business assigned to him with a dignity and propriety suitable to its delicacy and importance. In the case of lord Melville, as well as in that of Mr. Pitt, he knew how to distinguish between the man and the minister; and to pay a just tribute to the talents and dispositions of the former, whilst he criminated and condemned the latter. Having differed with Mr. Pitt with regard to his political measures almost through the whole of his public life, he took the opportunity which the trial of lord Melville afforded him of paying a just tribute of respect to his abilities and virtues, when his premature death must have vindicated the eulogist from the slightest suspicion of insincerity and adulation.

Of the new administration, he was a steady supporter; but though he had at an early period enlisted himself under the banners of Mr. Fox, and the earl Grey, his school-associate and brother-in-law, who was one of its distinguished members: he was their friend as ministers, not from personal and selfish motives, but from a conviction of his judgment that their principles and views were most favourable to the liberty and welfare of the British empire. Indeed he was regarded by many as an impracticable man, because in all great questions he was influenced by principle more than by any private and party attachment. What were his sentiments of the coalition ministry, and what were the grounds of the support which he afforded them, he had an opportunity of stating in the most explicit manner. At this time sir Francis Burdett offered himself a candidate for the county of Middlesex, and transmitted a circular letter to Mr. W., who had voted for him twice before, soliciting his support. This letter contained reflections on the coalition ministry, which led the subject of this article to decline giving his vote for sir Francis, and also to express his sentiments of the coalescing parties, which had been severely censured. "I have supported the present administration," says Mr. W., "from a conviction that they were united upon principles of real public utility, and for the purpose of carrying into execution plans of great national improvement, both in our foreign and domestic circumstances; and I cannot abandon them, because in a situation more difficult than that in which any of their predecessors have ever stood, they have not been able to effect what I believe to have been nearest the hearts of them all—I mean a peace with France; seeing such a peace could not have been obtained on terms consistent with national honour, and because time has not sufficed to mature and execute the schemes of internal improvement, which they have manifested their determination to pursue," &c. Having stated some other opinions with regard to the union of parties, in which he seems to have disagreed with sir Francis, he concludes: "These radical differences render it impossible for me to assist you in becoming a member of parliament. Different opinions may be maintained consistently with mutual and entire personal respect; such as I unfeignedly profess towards you. The determination you have taken to avoid the expence of conveyance and decorations so conspicuous at your former elections, does you honour; and I wish such an example could be followed by all other candidates," &c. The publication of this correspondence threatened a very undesirable termination; but it was happily prevented by the interposition of friends.

During this period, Mr. Whitbread took an active part in public affairs, and distinguished himself on a variety of occasions, guarding on the one hand with vigilant jealousy against an undue exertion of the royal prerogative, and on the other against its infringement by the democratical part

of the constitution. In February 1807, he renewed his attention to the existing system of poor laws, as it was his wish and incessant endeavour to improve it, and in so doing to render the peasantry happier, better, and less dependent. It was also an object, which he conceived to be of essential importance, to controul the several branches of public expenditure, and thus to relieve the distresses of the country. Much depended, he well knew, on peace with France, and to this desideratum his views and efforts were constantly directed. But he was almost ready to despair of this desirable event, "from the awful moment that death closed the scene upon the enlightened statesman (Mr. Fox) who had first commenced the negotiation." When the Grenville administration was obliged to retire, and a new parliament was convoked by their successors, he published a spirited address to his constituents, in which he stated the measures which had been projected and wholly completed or commenced during the existence of the late ministry, and the part which he had taken in the deliberations of the preceding parliament, closing with these memorable words: "I court your inquiry, and if you are satisfied in the result of it, I hope for your votes in the present election. If you do me the honour again to return me, I shall indeed be proud of it, and I will again endeavour to do my duty." The next important object of his attention was the education of the poor, as intimately connected with their morals and religion; but unable to obtain a legislative sanction to his plan, he was under a necessity of recurring to individual exertions and private subscription. During the important debates that occurred in 1809, with regard to the orders in council, he concurred with those who condemned this measure, and contributed first to their suspension, and at length to their utter discontinuance. With regard to the situation of Spain, he was one of those who censured the conduct of the French government, and who wished the natives to be stimulated to new exertions in behalf of the independence of their native country. "In 1809," says one of his biographers, "he took an active part in the inquiry and examination into the conduct of the royal duke who presided over the army, and although he found much to blame on that occasion, yet, at a future season, he seized the first opportunity to afford his testimony in behalf of his royal highness, whose administration as commander-in-chief had contributed not a little to the happy and glorious termination of the late contest. That event did not prevent him, however, after the overthrow of Buonaparte's government, from blaming the conduct of the Congress, and exposing the ambitious views of some of the sovereigns, particularly in respect to Saxony. On the return of the emperor from his exile in the island of Elba, the member for Bedford strongly and emphatically censured the declaration of the allies, more especially that part of it which seemed to recommend the detestable principle of assassination. He also loudly insisted both on the impolicy and injustice of a new war, on the ground that the executive power of the enemy was vested in the hands of any one particular person. But above all things he protested against the forcible restoration of the Bourbons by a foreign force, and the assumed right of dictating a government to France. Yet he most cordially joined in a vote of national gratitude to the duke of Wellington, for the memorable victory at Waterloo, although he at the same time boldly avowed that events had not altered his sentiments in respect to the pretended justice of the original contest."

In the variety of his personal and domestic concerns, in his attendance on parliamentary duties, and in his efforts for establishing and promoting institutions of public utility, and more especially such as pertained to the instruction

WHITBREAD.

instruction of the poor, Mr. Whitbread was assiduous and indefatigable; and whilst he was overwhelmed by a multiplicity of occupations, he voluntarily undertook a more Herculean labour than any other, which was the arrangement of the perplexed concerns of Drury-lane theatre. With every moment of his time thus occupied, and his mental powers unremittingly exerted, it is no wonder that his health should decline, and that his mind itself, though naturally vigorous and ardent, should be impaired by excess and intenseness of application. The consequence that might have been apprehended unhappily occurred, and the world was prematurely deprived of the benefit of his valuable services. "His countenance changed; he became drowsy, lethargic, and irritable; and he even supposed himself to have fallen into contempt." These indications of corporeal and mental decay were alas! too soon succeeded by that fatal catastrophe, which occurred on Thursday, July 6, 1815. "An inquest having been summoned by Mr. Gell, the coroner, met at eight o'clock the same evening, at the house of the deceased, No. 35, Dover-street, Piccadilly, and having entered his study, beheld Mr. Whitbread lying on his back, his arms and legs extended, with a deep incision on his throat from ear to ear, a small part in the front of the throat excepted. A looking-glass was opposite to him; his apparel and the floor were covered with blood; and the fatal razor was found at some distance!"

The verdict of the jury was as follows:—"That the deceased Samuel Whitbread, esq. died by his own hand; but that he was in a deranged state of mind at the time the fatal act was committed." His principles and character have been justly delineated by one of his biographers, and we shall select such particulars as are consistent with our contracted limits. "In politics he was a whig; yet a whig of the old school; one who wished to balance the royal power, by means of a due influence of the popular branch: but at the same time firmly and steadfastly to uphold both. Accordingly, he was always a strenuous, constant, and uniform advocate for a reform of the house of commons: but this great measure was grounded on the ancient and acknowledged bases; not on the visionary plans of annual parliaments and universal suffrage! As a patriot, he wished for the happiness and prosperity of his country; but these, he deemed most likely to be acquired, and most permanently enjoyed by cultivating the arts of peace; advancing the commerce; cherishing the manufactures; and encouraging the agriculture of his native land. Wars might indeed be popular, successful, glorious; but it was also incumbent and imperative that they should be both just and necessary. It was his firm opinion, that economy was to the full as proper for a state as for a private family: he was always, therefore, a decided friend of order, regularity, and good management. He hated jobs; he viewed placemen, courtiers, and contractors, with a jealous eye; and he disliked both unnecessary and excessive pensions, not only on account of the sums thus perverted from the public revenue; but also from their obvious tendency to produce meanness, sycophancy, and dependance.

"Mr. Whitbread was a strenuous advocate for national education, or instruction on a great scale. But finding himself unable to obtain a national sanction to this measure, he contented himself with his assistance and support as a private individual.

"He was an encourager of the fine arts; and always desirous that they should enjoy protection and applause."—"To agriculture, as a science calculated to advance the best interests of the nation, he paid particular attention."—"Horticulture also engaged his notice, and the gardens, and lawns,

and groves of Southwell, might have all been exhibited as fo many perfect specimens of care, neatness, and propriety.

"Although always doubtful of the justice of the late war, he never hesitated for a single moment as to the propriety of arming and defending his native country against the menaces and attacks of her enemies. He himself raised and commanded a body of sturdy yeomanry; and while he thus excited a martial ardour in his neighbourhood, he forgot not to enforce his favourite plan of fitting men, by means of education, for their respective situations in life. On this occasion, he instituted a school for the benefit of the non-commissioned officers; and contributed by all the means in his power to render it effectual.

"An only son, born and matured with the expectations of great opulence; it is but little surprising if he occasionally displayed a certain degree of haughtiness in his demeanour. Indeed it cannot be denied, that at times he appeared somewhat haughty and overbearing; but on the other hand, he must be allowed to have been admirably fitted for command; and was seldom known to exceed the bounds of moderation, but when he combated the injustice of power, assailed the infulence of office, or endeavoured to expose successful guilt to shame and to punishment.

"His heart constantly glowed with all the social affections. He was zealous in his friendships; while his enmities were transient and short-lived. His ear was ever ready to listen to the tale of the oppressed; his purse always open to succour those who had been reduced to distress by unexpected calamities. At length, after having lived and acted during the stormy politics of the French revolutionary contest, he was suddenly cut off, at a period when his services might have proved highly advantageous to his country; when the deceitful calm of peace seemed pregnant with greater and more formidable dangers than those arising out of a long, widespread, expensive, and destructive warfare!

"On the 11th July, 1815, when the marquis of Tavistock, on moving for a new writ for the borough of Bedford, decanted on the character, worth, and talents of the late member, his encomium was listened to amidst the loud cheerings of both sides of the house of commons:

"'Accustomed to defend his opinions with warmth and earnestness,' said he, 'the energies of his ample and comprehensive mind, would never permit the least approach to tameness or indifference. But no particle of animosity ever found a place in his breast, and he never carried his political enmities beyond the threshold of this house. It was his uniform practice to do justice to the motives of his political opponents; and I am happy to feel, that the same justice is done to his motives by them. To those who were more immediately acquainted with his exalted character; who knew the directness of his mind, his zeal for truth, his unshaken love of his country, the ardour and boldness of a disposition incapable of dismay, his unaffected humanity, and his other various and excellent qualities, his loss is irreparable. But most of all, will it be felt by the indigent in his neighbourhood. Truly might he be called the poor man's friend. Only those who, like myself, have had the opportunity of observing his conduct nearly can be aware of his unabated zeal, in promoting the happiness of all around him. His eloquent appeals to the house in favour of the unfortunate, will adorn the pages of the future historian; while at the present moment, they afford a subject of melancholy retrospect to those who have formerly dwelt with delight on the benevolence of a heart that always beat, and on the vigour of an intellect which was always employed for the benefit of his fellow-creatures!'"

He

He left behind him by lady Elizabeth, his mourning widow, two sons and two daughters.

The following memorandum of Mr. Whitbread's sudden death was written immediately after the lamentable event was ascertained, in the title-page of a very ancient edition of Cicero's "Paradoxa," by a friend who highly respected the stern virtues both of his public and his private character:—

SAMUEL WHITBREAD, armiger;

Vir illustis iste, quem omnes liberales brevi in tempore appellabunt

ANGLICUM CATONEM,

E terra fuit ereptus die sexto Julii, anno Christi 1815.

Ann. Biog. and Obit. for 1817.

WHITBURN, in *Geography*, a township of England, in the county of Durham; 4 miles N. of Sunderland.

WHITBY, DANIEL, a learned divine of the church of England, was born at Ruffden, in Northamptonshire, in 1638, and admitted to Trinity college, Oxford, in 1653, where he took the degree of M.A. in 1660, and became fellow of his college in 1664, in which year he first appeared as a writer against popery. In 1668 he was appointed chaplain to Dr. Seth Ward, bishop of Salisbury, and collated to a prebend in his church. In 1672 he took the degree of D.D., and about this time was made rector of St. Edmund's parish in Salisbury. From this time he became a considerable writer in the popish controversy, publishing "A Discourse concerning the Idolatry of the Church of Rome," 1674; "The Absurdity and Idolatry of Host-Worship proved," 1679; "The Fallibility of the Roman Church demonstrated," 1687; and "A Treatise of Traditions," in two parts, 1689. He also expressed, in common with several other liberal persons at this period, his wishes for an union of all Protestants, in a piece published in 1683, and intitled "The Protestant Reconciler; humbly pleading for Condescension to Dissenting Brethren in Things indifferent and unnecessary, for the Sake of Peace, &c." This publication was too liberal for the times, and called forth a host of adversaries. But the most formidable attack was that of the famous Oxford decree, which passed a censure on the following propositions contained in it; *viz.* "It is not lawful for superiors to impose any thing in the worship of God that is not antecedently necessary;"—"The duty of not offending a weak brother is inconsistent with all human authority of making laws concerning indifferent things;" which propositions were denominated in the decree false, impious and seditious doctrines; and the book was burnt in the quadrangle of the university schools. But it was still more humiliating to the author to be required by his patron, the bishop, to declare his sorrow for having written the work, and to renounce by name the two preceding propositions. This conduct was very unworthy of a Christian bishop, and fixes a permanent stigma on the memory of Ward. It reminds us of the Inquisition and Galileo. (See GALILEO.) Dr. Whitby, actuated probably by a desire to conciliate his adversaries, or urged to adopt this measure, published in the same year a second part of the book, in which he strongly presses the dissenting laity to join in full communion with the established church, and replies to all the objections of the Non-conformists against the lawfulness of their complying with its rites and ceremonies.

No man could more sincerely rejoice in the Revolution than Whitby, nor more cordially welcome the emancipation

of British subjects from all kinds of tyranny. Accordingly he published two tracts in favour of the oath of allegiance required on the accession of king William; and in one of these tracts he maintains the principle in the English government of an original contract between the prince and the people.

His capital work, however, was the result of fifteen years' study, and is intitled "A Paraphrase and Commentary on the New Testament," 2 vols. fol. printed in 1703, several times reprinted, and held in high estimation by biblical students. To the edition of 1710 he annexed a Latin appendix, containing an examination of Dr. Mill's various readings, under an apprehension that they might prove injurious to the authority of Scripture. This great work of Dr. Whitby was followed by several tracts on theological subjects, in which he seems to value himself on that freedom of discussion which, with new times, he was allowed to indulge, more especially as he occasionally strays beyond the fixed boundaries of what has been called orthodoxy. Among these tracts were, "The Necessity and Usefulness of the Christian Revelation;" "A Discourse concerning the true Import of the Words Election and Reprobation;" "The Extent of Christ's Redemption;" "The Grace of God;" "The Liberty of the Will;" "The Perseverance or Defectibility of the Saints;" "Four Discourses on Election and Reprobation;" "A Treatise on Original Sin," in Latin, in which he denies that the imputation of Adam's sin to his posterity has any fair ground in Scripture. Upon the publication of Dr. Clarke's "Scripture Doctrine of the Trinity," Dr. Whitby adopted his opinion, and wrote a Latin treatise, intended to prove that the controversies respecting the Trinity could not with certainty be determined from fathers, councils, or Catholic tradition. In connection with this subject of controversy, he published "A Dissuasive from Inquiry into the Doctrine of the Trinity; or, the Difficulties and Discouragements which attend the Study of that Doctrine." In the Bangorian controversy, he was one of the auxiliaries of Dr. Hoadly, and printed several tracts. He also published several sermons. But his last work, which did not appear till after his death, was "The last Thoughts of Dr. Whitby, containing his Corrections of several Passages in his Commentary on the New Testament; to which are added Five Discourses; published by his express Order." In the preface to this work, written at the close of a long life of learned and laborious inquiry, the author says, "when he wrote his Commentaries, he went on too hastily in the common beaten road of other reputed orthodox divines; conceiving first, that the Father, Son, and Holy Ghost, in one complex notion, were one and the same God, by virtue of the same individual essence communicated from the Father; which confused notion (he adds) he is now fully convinced to be a thing impossible, and full of gross absurdities." A short illness closed the life of this eminent biblical scholar, on March 24, 1725-6, at the age of 88. He is represented by a biographer as a man of great simplicity of character, singularly ignorant of worldly affairs, entirely devoted to his studies, but affable, pious, and charitable. He preserved a tenacious memory to the last, but through a defect of sight was obliged to employ an amanuensis. Biog. Brit.

WHITBY, in *Geography*, is a considerable sea-port town of the North-Riding of Yorkshire, England, situated between Flamborough-head and the entrance of the river Tees. Considering the ruins of the ancient abbey as the principal object of the town, the latitude of Whitby is 54° 29' 24" N., and the longitude 0° 35' 59" W. from the meridian of Greenwich. It is 47 miles N.E. of York, and

WHITBY.

246 miles from London. The town is placed at the mouth of the small river Esk, which divides it into two unequal parts. The direction of the river, running nearly due north towards the sea, determines that of the town, which extends along its banks. These banks rise almost suddenly from the river on both sides; particularly on the east, so as to leave but a very narrow stretch of level ground at the bottom, of which, indeed, a great part has, at different times, been gained from the bed of the river. This narrow space is literally covered with houses; but the town ascends the steep banks on both sides, and thus presents a romantic appearance, especially when viewed from the sea; the whole surmounted by the old weather-beaten church, on the verge of the eastern cliff, and the venerable remains of the abbey behind. The eastern half of the town extends about three-quarters of a mile; but the breadth where greatest does not exceed 150 yards. The western division is the largest, the most compact, and the most elegant. Although now of importance, Whitby was but inconsiderable in trade and population, until towards the beginning of the last century. Its origin may, however, be carried back to the foundation of the celebrated monastery in the seventh century. That the Romans, or the original Britons, had any establishment at Whitby, we have no grounds to affirm; although the opening of the river into the sea must have afforded a convenient station for fishing and navigation; of which, had the Romans been a commercial people, they would doubtless have availed themselves, especially on a tract of coast so little furnished with harbours adapted to their shipping. On this part of the coast may, perhaps, be placed the bay mentioned by Ptolemy, under the romanized name *Dunum Sinus*, of which the most commodious inlet was the mouth of the river, now, by a peculiar appropriation of a generic British name for water, called the Esk. After the establishment of the monastery of St. Hilda in the seventh century, the vicinity began to be inhabited. Under her successor Ælfleda, daughter of Oswy, the port had some share of shipping; for, in 684, the abbess took a voyage, with some monks of the abbey, to the isle of Coquet, on the coast of modern Northumberland, to have an interview with St. Cuthbert. Suffering and again restored with the abbey, after the devastation by the Danes in 867, Whitby obtained its present name, signifying the White town. It was also from the monastery occasionally called Presteby, or Priesttown. Although unnoticed in *Domesday-book*, Whitby, prior to 1189, had become of such importance, that the abbot erected it into a borough, with the customary privileges. Those privileges were soon after confirmed by a royal charter; and had no unfair means been employed to set them aside, Whitby might now have been a royal borough. But the liberties of Whitby were of short duration: the monks repented of their liberality to the town, and Peter, the succeeding abbot, in 1200, procured from king John a repeal of the charter of his predecessor. About the year 1538, Whitby is described by Leland as a "great fisher town;" and nothing more is added by Camden, who mentions the place fifty years later. For many years after the dissolution of the abbey, the vessels of the port were few and small; and the trade was inconsiderable until the establishment of the alum-works at Guisborough, at the close of Elizabeth's reign. A spirit of emulation being excited by the success of those works, a similar establishment was formed in 1615 at Sand's-end, within three miles of the town. The vicinity of Whitby abounding with the alum-mineral, other undertakings of the same kind were begun. Hence two important branches of industry were formed in the town; the one to supply the

alum-works with coal, the other to export the alum to distant parts. From these beginnings, the trade of Whitby increased; the schemes of the inhabitants were enlarged; the number of shipping was augmented; and new ships were constructed, for which timber was drawn from the oak-woods of the vicinity. In this manner, the trade and navigation of the town grew up to such a height, that, in the beginning of the present century, Whitby was the seventh in rank for tonnage among the ports of England. In 1816, the number of vessels belonging to the town was 280, carrying 46,341 tons, and navigated by 2674 seamen. Besides the carrying of coal, with the alum trade, and a share of foreign commerce, the number of vessels fitted out from Whitby for the Greenland whale-fishery, begun in 1753, was, in 1800, next to that of those sailing from London. As early as the middle of the 16th century, small wooden piers were constructed at the mouth of the Esk, for the protection of the fishing-craft: but in 1632 stone piers were begun, through the exertions of sir Hugh Cholmley, who, by the favour of the earl of Strafford, his relation, obtained a general contribution over England in aid of the work, when nearly 500*l.* were collected. The navigation of Whitby becoming of importance, acts of parliament were obtained, in 1702 and 1723, for constructing a pier, which now extends above two hundred yards from the cliff on the east side of the harbour, westward to the channel of the Esk. By this work, security was obtained for the town as well as the shipping, both of which were greatly exposed to north-easterly winds. Another pier, on the west side, was afterwards added, running out about an equal distance towards the sea. By subsequent additions and improvements, the harbour has been essentially benefited. The west pier, now carried out to the length of three hundred and forty yards, is constructed with large blocks of squared stone, and terminates in a circular head, with embrasures for a battery. Within the piers, vessels to the number of five hundred may lie, but all on the ground at low water. The harbour is divided into the outer and the inner by a drawbridge, so constructed as to allow ships of two hundred tons to pass through. In the latter, which is capacious and secure, on both sides of the river are constructed several dry docks, and other accommodations for ship-building. The vessels built for the coal-trade are particularly valued for their strength and durability. One built in 1724 was lost on the Lincolnshire coast in 1810, but did not go to pieces: another, wrecked a few years ago, was above one hundred years old. In neap-tides the water rises from ten to twelve feet at the entrance of the harbour; but in ordinary spring-tides the depth extends from fifteen to eighteen feet. In the equinoctial gales, the depth of water is sometimes increased to twenty-three or twenty-four feet. The trade of the port of Whitby is but small in proportion to its shipping, as many of the largest vessels are employed in time of war as transports, and at other times by the merchants of London, and of other ports. The trade of the town is, however, considerable for its situation, in a country abounding with moors, where few manufactures are carried on. The alum-works in the environs are of great antiquity, and may not improbably be carried back to the Roman times. But the first work established in Britain, in later times, was begun by sir Thomas Chaloner in 1595, on his estate at Belman-rock, near Guisborough, twenty miles to the westward of Whitby. Since that period, alum-mineral has been extracted in various other places, particularly at Sand's-end, three miles west from Whitby, where the work is still in a prosperous state. Until the year 1789, the alkaline lees

employed in the manufacture were prepared from kelp, or sea-weed, burnt on the shore: but since that period kelp has been gradually superdisplaced by black-ashes, made from the refuse of soap-boilers' lees. The average annual quantity of alum manufactured in the Whitby district, for the last twelve years, was 2840 tons; but in 1816 the quantity was 3155 tons. Little alum is now exported, nearly the whole being sent to London. The number of persons, including artificers and boys, belonging to the works, is about 600. (See ALUM.) Thin seams of coal have, for upwards of seventy years, been wrought in the environs of Whitby, but of a very inferior quality, and used only in the interior parts of the country.

Whitby contains no public building of note. The town-hall, erected by the late Mr. Cholmley, is a heavy pile of the Tuscan order. The poor-house, extensive, and judiciously managed, affords a comfortable refuge for the distressed, and tends to diminish the heavy burthen of the parish-rates. A dispensary, liberally supported, for distributing advice and medicines to the poor, was established in 1780. The parish-church stands near the top of a hill, on the east side of the town, a little to the northward of the ruins of the abbey, accessible from the bottom by an inconvenient ascent of 190 stone steps. The architecture of the edifice was originally what is absurdly styled Gothic; but it has gone through so many alterations, that little of its ancient appearance now remains. The church-yard is excessively crowded with grave-stones; but the sea-air of Whitby is so destructive of stones, that inscriptions are soon effaced. For the use of the numerous inhabitants, a spacious chapel of ease has been erected in the lower part of the town; and for the country part of the parish, which is of great extent, three others have been built. That at Sleights, four miles from the town, is a handsome edifice. Roman Catholics, Quakers, and various other classes of dissenters, have their respective places of worship in the town. According to the parliamentary returns of 1811, the houses of this town were 1395, and the inhabitants 6969: but in the spring of 1816, the population was found, by a careful inquiry, to have increased to 10,203. The inhabitants of the country part of the parish were then estimated at 1477 persons.

The town of Whitby is close, irregular, and unpleasant; but the environs are romantic and beautiful. These are embellished with the country-residences of the opulent inhabitants, mostly erected on commanding situations: the most interesting object of all, however, is the celebrated Abbey, of great antiquity, having been originally founded in the year 655. Before the sanguinary but decisive battle of Leeds, on the banks of the Oire, in which he utterly overthrew and slew his invading foe, Penda, king of the Mercians, Oswy, king of the Northumbrians, vowed, if successful, to erect and endow a monastery, and to consecrate to the service of religion in it his daughter Ælfleda, then scarcely a year old. In discharge of this engagement, he founded the monastery of Streonshalh, of the Benedictine order; with this peculiarity, that it was to contain both monks and nuns, all under the government of St. Hilda, the first abbess. It is, nevertheless, probable, that the introduction of the monks, by which the institution became in all respects similar to that of the celebrated abbey of Fontevraud, in the west of France, did not take place till several years after its establishment. The monastery was begun in 657, and dedicated to St. Peter; but such was the veneration entertained for St. Hilda, that it was always called by her name, and to her was the foundation usually ascribed. While Hilda was abbess, the synod of

Whitby was held in 664, in which, notwithstanding her opposition, strengthened by that of Colman, the festival of Easter was directed to be celebrated at the time adopted by the sovereign pontiff, instead of that which had been in general observance in Britain. Dying in 680, Hilda's place as abbess was filled by Oswy's daughter, Ælfleda. Till the year 867, the abbey continued to prosper; but it was then overthrown by the sons of Lodbrog the Dane. In this state it remained until after the Norman Conquest: the lands in the neighbourhood were granted to Hugh, the first earl of Chester, from whom they passed to William de Percy, ancestor of the Percys of Northumberland. By him the monastery was restored from its ruins under a prior; but in the reign of Henry I. it was again raised to the rank of an abbey. Although pillaged by a Norwegian fleet in the time of abbot Richard, who died in 1175, its revenues at the dissolution, under Henry VIII., amounted to 505*l.* 9*s.* 1*d.* At this epoch, the site and lands, partly by grant and partly by purchase, became the property of sir Richard Cholmley, a descendant of the family of Cholmondeley, in Cheshire.

Of Whitby-abbey, the ruins of the church alone remain; but by these, which are still considerable and conspicuously picturesque, it appears to have been a magnificent structure. The exterior length of the church, which is built in the usual form of a cross, is 310 feet; the breadth at the west end, including the buttresses, is 84 feet; the length of the cross 153 feet. The church probably occupies the site of the Saxon building erected before the Conquest; but of it, nor even of the edifice constructed immediately after the revival of the monastery, no vestige now remains. The present structure is of different ages, and exhibits different styles of architecture. The eastern part, or choir, evidently the oldest, was probably built by Richard de Burgh, who was abbot from 1148 to 1175, and who rebuilt the chapter-house. The lower part of the tower, and most of the pillars, which are all clustered, were perhaps erected at the same time; but the north transept and the upper part of the tower are of a later date. The ornaments of the windows in those parts, the beautiful range of niches on the walls within, the tracery of the circular window in the north end, &c. seem to indicate the work of the close of the 13th or the beginning of the 14th century. The west front is the latest part of the whole, probably of the time of Edward III., or in the end of the 14th century.

The alum-rocks in the vicinity of Whitby are not less curious than valuable, from the variety of petrified substances they contain. Besides the usual petrifications of shells and other marine bodies, parts of the human skeleton have been occasionally discovered. In the early part of the last century, Dr. Woodward, the celebrated naturalist, dug up on the scar, or cliff, on the east side of the harbour, the petrified arm and hand of a man, having all the bones and joints very visible. About 1743 was found, in the alum-rock, the complete skeleton of a man; but it was broken to pieces by taking from the bed. A similar discovery is said to have been made about nine years ago; but the skeleton was broken without any scientific person having examined it. In 1758, the bones of a crocodile, as they were imagined to be, were drawn from the rock, and transmitted to the Royal Society, by whom an account of them was published in the 50th volume of the Philosophical Transactions. About four years afterwards, the skeleton of a horse was found in the alum-works at Salt-wick, thirty yards under the surface. Ammonites, or cornua-ammonis, vulgarly called snake-stones, abound, with other testaceous petrifications, in the aluminous schistus in the vicinity of Whitby;

Whitby; on which account, probably, the town has chosen three ammonites for its arms.

Robin-Hood's Bay, six miles south-east from Whitby, is a noted fishing-station, frequented for protection by many a vessel passing along that extended tract of inhospitable shore. Among the country-seats in the vicinity of Whitby, which are not numerous, is Mulgrave castle, the mansion of the earl of Mulgrave, situated five miles westward from the town, on a lofty eminence, commanding a most extensive prospect both by land and sea. Near to the southward stand the remains of the ancient baronial castle of Mulgrave. Manifest evidences of Roman occupation are to be seen in various parts of the surrounding country. The Roman road from *Eboracum* (York), northwards by the vicinity of New Malton, (perhaps the *Derwentio* of Antonine,) and apparently terminating at Durnsley, near the sea, three miles W. from Whitby, is in many places very perceptible. Along its course still remain traces of Roman encampments, of which the camps at Cawthorn, 19 miles S.W. from Whitby, supposed to be the *Delgovitia* of Antonine, are very perfect. These works are noticed in general Roy's "Military Antiquities of the Romans in Britain;" but much more particularly in "The History of Whitby and Streonshalh-abbey, with a Statistical Survey of the Vicinity," by the Rev. George Young, in 2 vols. 8vo. Whitby, 1817.

WHITCHURCH, a populous market-town in the north part of the hundred of North Bradford, and county of Salop, England, at the northern extremity of the county, is situated 20 miles N. by E. from Shrewsbury, and 160 miles N.W. by N. from London. The church, the chief object of notice, seated on the top of the hill over the town, is a spacious modern structure, erected in 1722, with a square tower 108 feet in height. Two recumbent stone figures are preserved from the ruins of the old church; of which one represents the celebrated John Talbot, the first earl of Shrewsbury, and marshal of the realm of France in the reign of Henry VI.: he was called the English Achilles, and was greatly renowned in the wars of France. Shakspeare, in his play of Henry VI., describes Talbot as a most formidable and magnificent character: "the terror of the French:—the scare-crow that affrights their children:—whose grizzly countenance made others fly:—none durst come near him for fear of sudden death." Another effigy represents Christopher Talbot, fourth son of John Talbot, second earl of Shrewsbury, and who was rector of Whitchurch and archdeacon of Chester. The rectory of this parish is one of the richest in the county. The castle has long been in ruins. Whitchurch has a very respectable free-school, in which many persons of eminence have been educated. Here are also meeting-houses for Protestant dissenters, a charity-school for children of both sexes, and six alms-houses for aged women, endowed by Mr. Samuel Higginson. A weekly market is held on Friday; and here are two annual fairs. The town is a place of much public resort during the horse-races which are occasionally held here. Among the natives of Whitchurch, was distinguished the celebrated linguist Abraham Whelock, who translated the New Testament into Persian, and assisted Dr. Brian Walton in the compilation of his polyglot Bible. Whelock published also an edition of the writings of the venerable Bede. He died in 1654. The population return of the year 1811 states the town of Whitchurch to contain 552 houses, and 2589 inhabitants: but the parish comprehends, besides the town, thirteen townships. The whole population is returned as 5332; the number of houses as 1107.

About nine miles to the northward of Whitchurch is Hawkstone-park, long the residence of the ancient family of the Hills, and a place celebrated for its natural and artificial beauties and curiosities. The mansion, an elegant modern building situated on the north side of a romantic hill, is adorned with a lofty portico of the Composite order. With the beauty of the exterior of the edifice, the interior fully corresponds: the chapel and the saloon are particularly elegant, and the latter is ornamented with valuable paintings. The grounds around the mansion are particularly interesting for their assemblage of naturally romantic scenes, to which art has greatly contributed. The grotto, the view from the cliff, called Paoli's-point, the retreat, or hermitage, St. Francis's cave, the Swiss bridge, the terrace, the obelisk, and the widely-extended prospect it presents over the surrounding country, the tower, the artificial river, the cottage, or whim, are among the many attractive features of Hawkstone-park, which owes much of its embellishment to the taste and munificence of the late sir Richard Hill, bart. The beautiful and romantic scenery of this noble place is fully detailed in T. Rodenhurst's "Description of Hawkstone."—Beauties of England and Wales, vol. xiii. Shropshire; by R. Rylance, 1811.

WHITCHURCH, a small but ancient borough and market-town in the upper half hundred of Evingar, Kingsclere division of Hampshire, England, is situated on the borders of Chute Forest, at the distance of 13 miles N. from Winchester, 24 miles N. by E. from Southampton, and 57 miles W.S.W. from London. It possesses the rights of a borough by prescription; and has sent two members to parliament since the twenty-seventh year of queen Elizabeth. The borough is the joint property of lord Sidney and lord Middleton; the freeholds, which give the right of voting, being conveyed by them to their respective friends for the purpose of performing the ceremony of an election. The freeholders are nominally about seventy, but the real electors are said to be appointed and influenced by the noblemen before-mentioned. The government of the town is vested in a mayor, annually chosen at the court-leet of the dean and chapter of Winchester, to whom the manor belongs. The town, though small, is remarkable for a variety of religious sects; there being, besides the church, places of worship for the Independents, Anabaptists, Quakers, Methodists, and Sandimianians. A market is held weekly on Friday, and three fairs annually. The population of the parish, as ascertained by the return of the year 1811, was 1407; the number of houses 281: the labouring classes are chiefly employed in woollen manufactures, and in agriculture.

Adjoining to the western end of Whitchurch is one of the entrances to the earl of Portsmouth's distinguished residence, Hurstbourne-park. Of late years the park has been much enlarged. The grounds contain considerable diversity of surface and scenery; and the conversion of a small stream into a broad piece of water, has tended very much to improve the place. In the old part of the park, trees have attained a size much beyond what might be expected from the chalk and flint which constitute so great a portion of the soil of North Hampshire. An old mansion-house stood in the bottom near the present parish-church and village: but the late lord Portsmouth pulled it down and erected the present building in a much more eligible and healthy situation. It stands on elevated ground, commanding extended and varied prospects, particularly to the south and the north. This mansion, erected by Mr. Meadows from the designs of James Wyatt, esq. consists of a centre and two correspondent wings connected to it by colonnades. The eastern wing contains the library and a chapel, and in

the western are apartments for servants. In the library were preserved a considerable body of the MSS. on various matters, philosophical and theological, of the illustrious Newton. They came into the possession of this family in consequence of the marriage of John, viscount Lymington, (son of the first earl of Portsmouth,) in 1740, with Catharine Conduit, great niece and coheirefs of sir Isaac. Those papers were examined by the late learned bishop (then doctor) Horsley, while preparing his edition of Newton's works. See NEWTON, *Sir Isaac*.

A little to the eastward of Whitchurch, near the London road, is Freefolk, noted for the paper-mills belonging to John Portal Bridges, esq. where the paper for the notes of the bank of England has been manufactured ever since the reign of George I. At Laverstock is the seat of William Portal, esq.; and in the adjoining parish of Overton is a handsome new house, the seat of — Jarvis, esq. In the village a silk-mill has been established. In various spots at no great distance from Whitchurch, are still visible evidences of Roman occupation. The great fofs-way, a Roman road leading from Sorbiodunum, or Old Sarum, to Vindonum, or Silchester, passes across the downs two miles to the northward of the town. Near the course of this way, at Egbury, a Roman encampment, forming an irregular quadrangle, may be easily traced, the rampart in most parts is still lofty; the longest side measures about 300 yards. On several eminences within the extent of a few miles from Whitchurch are circular or ring-polls, commonly called beacons; but evidently military stations of the ancient inhabitants of the country, to which they could resort, and on which they could secure their families and property, in the event of hostile assault from domestic or foreign foes.—*Beauties of England and Wales*, vol. vi. Hampshire; by J. Britton, F.S.A. and E. W. Brayley.

WHITE, GILBERT, M.A. in *Biography*, an agreeable writer of natural history, was born at Selborne in Hampshire in 1720, and completed his education at Oriel college, Oxford, of which he was elected fellow in 1744. In 1746 he took the degree of M.A., and in 1752 became one of the senior professors of the University. Unambitious in his temper, and fond of rural scenery, he fixed his residence in his native village, and devoted his time to literary pursuits, and particularly to the investigation of those subjects of natural history, which furnished him with lessons of piety and benevolence. The result of his observations was communicated to the public in his "Natural History and Antiquities of Selborne," 1789, 4to.; the first and principal part of which consisted of letters addressed to Mr. Pennant, and affords a variety of remarks, chiefly in the zoological departments, peculiarly amusing and no less instructive: and the second part treats of the antiquities of the place. Highly esteemed by all who knew him, he died in 1793; but after his decease, the natural history of his work was published separately in 2 vols. 8vo. 1802, with the addition of miscellaneous observations, and a Naturalist's Calendar, extracted from his papers, and of parallel remarks communicated by W. Markwick, esq., an accurate observer of nature in the county of Sussex. Gen. Biog.

WHITE, JOSEPH, Regius professor of Hebrew, and Laudian professor of Arabic, in the university of Oxford, was born in Gloucestershire in 1746, and being of humble origin, but devoted to reading whilst he was pursuing his father's occupation as a weaver, attracted the notice of a neighbouring gentleman, who sent him to Wadham college, Oxford. Having graduated M.A. in 1773, and chosen fellow of his college, he directed the main bent of his studies to the oriental languages, under the advice of Dr. Moor, after-

wards archbishop of Canterbury. Such was his proficiency in this department of literature, that in 1775 he was elected Laudian professor of Arabic, on which occasion he delivered and printed an oration on the utility of that language in theological studies. By the recommendation of bishop Lowth, he was appointed editor of the Philoxenian Syriac version of the four gospels, which he published in 1778. About this time he was nominated one of the king's preachers at Whitehall; and in a sermon preached before the university of Oxford, he recommended a revival of the English translation of the Old Testament. In 1780 he published a "Specimen of the Civil and Military Institutes of Timour," translated from a Persian version of the Mogul original, written by the conqueror himself. He also added a specimen of Persian poetry, and recommended the study of this language. These Institutes having been translated entire by major Davy, were published from the Clarendon press in 1783, under the inspection of professor White, who annexed a preface, indexes, and geographical notes.

As Bampton lecturer, to which office he was appointed in 1781, he preached a course of sermons before the university, which were printed in 1784, and much admired for their learning and eloquence. The general design of these sermons was to evince the excellence of the Christian religion, on a comparison with that of Mahomet. (See AL-CORAN.) It was discovered, however, somewhat to the disgrace of the professor, that he had derived very considerable assistance in the composition of these sermons from the masterly pen of Mr. Badcock, who had been a dissenting minister at South Molton, and afterwards conformed to the church, and that several of them were actually written by him. It was also known, that Dr. Parr, from his ample store of Greek literature, had furnished the materials that had been wrought up into two of these sermons. These facts were investigated and ascertained; and the charge against the professor was sufficiently substantiated, and it was founded, not so much on his want of ability for such productions, as on his indolence, and on certain habits unfavourable to study. His reputation, however, as a defender of Christianity was acknowledged, and he was presented to a prebend of Gloucester, and soon after was graduated D.D. About the year 1790 he married, and accepted a college-living in Suffolk. In this situation he prosecuted his studies, and having set up a press in his house, and furnished himself with oriental types, he and his wife performed the business of compositors, and a man and maid-servant that of the press. Hence originated his "Ægyptiaca," relating to the antiquities of Egypt; and an edition, with a version, of an account of that country by an Arabian writer named Abdollatif. In 1799 Dr. White published from the Clarendon press his "Diatessaron," or the harmony of the four evangelists, in Greek, a work useful to biblical students. He died in 1814, at the age of 68. Gen. Biog.

WHITE, one of the colours of natural bodies.

White is not so properly said to be any one colour, as a composition of all the colours; it being demonstrated by sir Isaac Newton, that those bodies only appear white, which reflect all the kinds of coloured rays alike, and that the light of the sun is only white, because it consists of all colours.

From the multitude of rings of colours, which appear upon compressing two prisms, or object-glasses of telescopes together, it is manifest, that these do so interfere and mingle with one another at last, as, after eight or nine reflections, to dilute one another wholly, and constitute an even and uniform whiteness: whence, as well as from other experiments,

it appears that whiteness is certainly a mixture of all colours; and that the light which conveys it to the eye is a mixture of rays endued with all those colours.

The same author shews, that whiteness, if it be most strong and luminous, is to be reckoned of the first order of colours; but if less, as a mixture of the colours of several orders: of the former sort, he reckons white metals; and of the latter, the whiteness of froth, paper, linen, and most other white substances. And as the white of the first order is the strongest that can be made by plates of transparent substances, so it ought to be stronger in the denser substances of metals, than in the rarer ones of air, water, and glass.

Gold or copper mixed either by fusion or amalgamation with a very little mercury, with silver, tin, or regulus of antimony, become white; which shews, both that the particles of white metals have much more surface, and therefore are smaller than those of gold or copper; and also, that they are so opaque, as not to suffer the particles of gold or copper to shine through them. And as that author doubts not, but that the colours of gold and copper are of the second or third order, therefore the particles of white metals cannot be much bigger than is requisite to make them reflect the white of the first order. See COLOUR, and *Colours from METALS*.

Hevelius affirms it as a thing most certain, that, in the northern countries, animals, as hares, foxes, bears, &c. become white in the winter time; and in summer resume their natural colours.

Black bodies are found to take heat sooner than white ones; by reason the former absorb or imbibe rays of all kinds and colours, and the latter reflect all.

Thus, black paper is sooner put into a flame, by a burning glass, than white; and hence black cloths, hung up by the dyers in the sun, dry sooner than white ones. See BLACK.

WHITE of the Eye, denotes the first tunic or coat of the eye, called *albuginea* and *conjunctiva*, because it serves to bind together or inclose the rest. See ADNATA, and EYE.

WHITE Ale, in *Rural Economy*, a liquor of the malt kind, which is said to be prepared somewhat in the following manner. Twenty gallons of malt are mashed with the same quantity of boiling water; when after standing the usual time, the wort is drawn off, and six eggs, four pounds of flour, a quarter of a pound of salt, and a quart of *grout*, are well beaten up together, and mixed with the above quantity of wort, which, after standing twelve hours, is put into a cask, and is ready for use the day afterwards.

It is observed by the writer of the Devonshire Corrected Report on Agriculture, who has supplied the above account, that this liquor is almost exclusively confined to the neighbourhood of Kingsbridge, in that county; and that it is a beverage which possesses a very intoxicating quality, and which is much admired by those who drink not merely to quench thirst. A mystery, it is said, hangs over the ingredient called *grout*, and the secret is said to be confined to one family in the above district only. No difficulty, however, it is supposed, could arise in ascertaining its component parts, by submitting a certain portion of it to the test of chemical examination. It is plain, it is said, that this liquor is of considerable antiquity, from the *terrier* of the advowson of Dodbrook, which expressly calls for the tithe of white ale.

This mild pleasant liquor may easily be made in other places.

WHITE Antimony Ore, in *Mineralogy*, *Antimoine Oxydée*,

Haüy, generally occurs diffused and crystallized in veins along with other ores of antimony on primitive rocks. See ANTIMONY.

WHITE Arsenic, and *Asbes*. See the substantives.

WHITE Bait, in *Ichthyology*. See CLUPEA.

WHITE Beam. See CRATÆGUS.

WHITE Bear. See POLAR Bear.

WHITE Brant, the *Anas Hyperborea*. See DUCK.

WHITE Bug, in *Gardening*, an insect of the bug kind, which is often very troublesome and hurtful in vineries, peach-houses, and other such sorts of houses for fruit-trees.

It is observed in the first volume of the "Memoirs of the Caledonian Horticultural Society," that the cause of this insect so frequently making its appearance in these houses, is much owing to the neglect in not washing the trees properly every day with the engine in many cases. That when a vinery is much overrun with it, in order to its removal, all the old bark should be stripped from off the vines, and all the shoots and trellis be properly sponged over with black soap and warm water. The writer always makes it a rule, at the time of the winter-pruning, to take off the outer bark, whether infested with them or not, as these bugs lodge between the old and new bark. That in regard to peach-trees, which are infested in this way with the white bug, they should be sponged all over in the same manner in the winter season; and if any bugs should appear in the spring, it is a good way, it is said, to tie pieces of mat round the stems and large branches of the trees; as about these parts these insects take shelter from the heat of the sun. Once every day these portions of mat should be taken off, and thrown away out of the houses. That soon after forcing is begun, the female of these bugs will be observed to be much larger than the male, at which time she constantly goes into some hollow of the trees or bark, and deposits her ova or eggs mostly in some thousands. These are easily capable of being discovered, and may be picked out of such hollows or crevices by means of a large pin, or small piece of sharpened stick; which is an effectual way of getting quit of them, and of preventing their future increase. See WASHING Fruit-Trees.

WHITE Campion, in *Agriculture*, a pernicious perennial weed in corn lands, pastures, and hedges, which is often difficult to destroy, except by good summer tillage of the ground. See WEED, and WEEDING.

WHITE Caterpillar, or Borer, in *Gardening*, a very destructive sort of insect of this kind, but which is not so numerous as those of the other kinds, nor does it attack and destroy the same parts of gooseberry-bushes, though equally injurious on others. It is of comparatively a small size too, in relation to those of the other sorts, the black and green, that infest these bushes; the former of which, the large or black, may be observed, it is said in a paper in the Horticultural Transactions of Scotland, lying during the winter months in large clusters on the under parts, and in the crevices of the bushes of these sorts; and that even in the month of February they have been found in that state. But that in the course of eight or ten days after that, if the weather be favourable, they will creep up the bushes in the day-time, feed on the young buds, and return to their nest during the night. That whenever leaves appear upon the bushes, they feed upon them until they arrive at maturity, which is generally about the month of June; after which they creep down upon the under sides of the branches, where they lodge until the crust or shell is formed over them. That in July they become moths, and lay their ova or eggs on the under sides of the leaves and of the bark. That the produce

produce of these ova or eggs, which come into life during the month of September, feed on the leaves so long as they continue green, and afterwards collect and gather together in clusters on the under sides of the branches, and in the cracks and openings of the bark, where they abide all the winter, as has been already seen. Consequently that winter is the most proper time for attacking and destroying this sort of these insects with success, as their destruction is then most effectually and completely accomplished by merely the simple operation of sprinkling and pouring a quantity of boiling hot water over and upon them, from a watering-pan or pot, by which no injury, it is said, will thereby be done to the bushes or gooseberry fruit-shrubs.

That the latter or green sort are in the shelly state in February, when they lie about an inch under the ground. That in the following month they come out small flies, and immediately lay their ova or eggs on the veins and under sides of the leaves. That these ova or eggs produce young caterpillars in the month of May, which feed on the leaves of the bushes until June or the succeeding month, when they cast off a blackish kind of skin, and afterwards crawl down from the bushes into the earth, where a sort of crust or shell grows over them, and in that state they continue until the following April.

The only method which this writer has hitherto found effectual in destroying this sort of these gooseberry-caterpillars, is first to dig the ground all around the bushes very deep during the winter season, by which means the greater part of them are either destroyed, or buried too deep ever to rise to the surface: or, secondly, in the month of April, when the flies make their appearance, to pick off all the leaves on which any ova or eggs are to be discovered, which is a tedious operation, but may be performed by children. If any of the insects should escape both these operations, they will, it is said, be discernible as soon as they come into life, by their eating holes through the leaves, and may then be easily destroyed, without the least injury to the bushes or fruit.

That this white kind bores the berry, and causes it to drop off from the bush. That they preserve themselves during the winter season in the chrysalis state, about an inch under ground, and become flies nearly at the same time with the latter of the above kinds. That they lay their ova or eggs on the blossoms, and that these eggs produce young caterpillars in May, which feed on the berries until they are full grown, and then creep down into the earth, where they remain for the winter in the shell state.

This sort of these caterpillars, too, may be best destroyed in the winter season, by having the land well and deeply dug all about the gooseberry-bushes at that time of the year, and by preventing them from climbing up the stems of the plants in the early spring season, for the purpose of laying their eggs, by every possible means that can be devised and resorted to by the gardener.

These are the best and most effectual methods that have yet been discovered by this writer, for the destruction of this and the two other sorts of gooseberry-caterpillars. For though many other modes of doing it have been tried, none have been found so certain and complete as these; and they have this advantage and consideration to recommend them, that they injure neither the bush nor the fruit. That the same thing cannot be said either of tobacco-liquor, snuff, or soap-suds, all which render the fruit constantly bitter and ill-tasted; and which, whatever may be the effect that they may have upon the smaller kind of caterpillars, it is certain, the writer thinks, that they have none upon the larger kinds, and that foot, lime, and lime-water, do not affect any sort

of caterpillar whatever, as the writer has sufficiently proved by repeated experiments with such substances.

WHITE Centaury, in *Agriculture*, an annual weed in woods and other such places; of which animals in general are not fond. It is said to form the basis of the famous Portland powder for the gout. See *WEED*.

WHITE Cinnamon. See *CINNAMON*.

WHITE Clover, in *Agriculture*, a well-known plant of the clover kind, which is perennial, and consequently lasts a number of years in the soil or land. It is said to require a deep free soil to bring it to any degree of luxuriant growth. Consequently but little of the land in many districts suits it; but it is sometimes sown with the common clover in about half the quantity. In the Berkshire Report on Agriculture, it is stated, that it is frequently confounded with the Dutch clover, that it affects a light soil, that it is much improved by rolling, and that it yields a very sweet hay when mixed with red clover, rye-grass, and nonsuch. That sheep are not very fond of it; and this is, probably, one reason why it is less cultivated than it deserves to be. It appears, it is said, to be the Irish shamrock; and that the powdered flowers of this clover being made into bread, were eaten by the natives of the sister island before the introduction of potatoes. It may be noticed, too, that it is capable of bearing flooding, which the red clover is not, and this is a very great advantage in its favour.

It is remarked also, that the real Dutch clover is not unfrequently sown with other grasses, in a larger or smaller proportion, as the farmer may think proper. That in some places of the above county it is the common practice to sow of broad clover eight pounds, yellow trefoil, or hop clover, four pounds, and of Dutch or white clover, two pounds, to the acre. If it be sown alone, about eight or nine pounds will be sufficient. It is getting into high estimation in the neighbourhood of Bray, in the above district, and in other places, and is sometimes called honey-suckle grass, from the sweetness of its smell. That to all sorts of cattle it forms an agreeable pasture, and especially to sheep, which thrive on it prodigiously. Even swine will fatten on this grass, the seed of which was imported from Flanders for some time after it began to be cultivated in this country, though it appears to be an indigenous plant. It has the excellent property of never wearing out by being close fed. See *TRIFOLIUM Repens*, and *HYBRIDUM*. Also *CLOVER*.

White clover is laid, in the Gloucestershire Agricultural Report, to be injurious to cow-stock, by *hoving* them when in abundance after rain in pastures.

WHITE Colours, in *Painting*, comprehend the following; *viz.* *FLAKE-White*, *White-LEAD* or *CERUSSE*, calcined or burnt *Harts-HORN*, the perfection of which depends upon its whiteness and firmness, distinguishable both by sight and touch, *PEARL-White*, *TROY-White*, and *EGG-Shell White*. (See the several articles.) The most delicate and perfect white in use, in its application to the purposes of painting in water-colours, is the artificial sulphate of barytes. According to Mr. Parkes (*Ess.* vol. ii.), it was first recommended and brought forward by Mr. Hume, of Long-Acre, who has long supplied the public with it under the name of "Permanent White." The same ingenious practical chemist says, that he knows of nothing so well calculated as this for marking bottles in a chemical laboratory, where the gases soon destroy the ink of common labels, and render them illegible. It is equally useful for marking jars, bottles, or boxes, which must be kept in a damp cellar, for it is not only imperishable in such situations, but preserves its extreme whiteness, and consequently the distinctness of the characters. We learn also from sir Humphrey

Davy's "Elements of Chemical Philosophy," that the combination of barytes and carbonic acid, made artificially by pouring a solution of carbonate of ammonia into a solution of nitrate of barytes, forms also a pigment of a very white colour.

WHITE Colours, in Dyeing. See COLOUR.

WHITE Copper Ore, in Mineralogy, is one of the rarest ores of copper, and has frequently been confounded with copper pyrites, and other ores of that metal. (See COPPER Ores.) Its colour is between silver-white and bronze-yellow; it occurs massive and disseminated; it has a metallic lustre. The fracture is fine-grained and uneven; it yields easily to the knife. The specific gravity of this ore is 4.5. It contains about 40 per cent. of copper mixed with iron, arsenic, and sulphur.

WHITE Copperas, Cordage, Eagle, and Egg-Shell. See the substantives.

WHITE Coss-Lettuce for Hogs, in Agriculture, the use of it in feeding these animals. A trial of it in this way is stated to have been made in Sussex, which is particularly deserving of attention: the weaning of young pigs, without much milk and some corn, is often a difficult business; but if this sort of lettuce will do it, which seems to be the case, no farmer should ever be without a rood, or half an acre of this sort of crop for this use.

In this trial, four ounces of this sort of lettuce-seed were sown very thick over two perches of ground in the beginning of March. A crop of potatoes was in rows at three feet distance; between which a double row of these lettuces was planted in May; both crops being afterwards kept clean by hand-hoeing. In the June following, they were begun to be used for three sows with little pigs, which were kept on these lettuces for six weeks; but these sows had wash in addition: the pigs were then weaned a fortnight earlier than usual; and after the weaning, the great use of the lettuces was found, for the pigs did admirably well upon them, until they all were gone in the middle of August. They were then fed as usual, with cabbage, turnip-tops, and other such vegetable matters, but fell off at once for want of the lettuces. See LACTUCA, and LETTUCE.

WHITE Crops, a term applied to all sorts of grain-crops, as wheat, rye, barley, oats, and some others, in contradistinction to those of the green and culmiferous kinds, such as cabbages, turnips, rape, tares, beans, and some others of a similar nature.

WHITE Darnel, a very troublesome and prolific weed among corn-crops, especially of the wheat kind. See WEED, &c.

WHITE Enamel. See ENAMEL, and ENAMELLING.

WHITE Face, or Blaze, in the Manege, a white mark upon a horse, descending from the forehead almost to the nose. It is called in French *chanfrin blanc*.

WHITE Film, or Blindness, a disease in sheep, which is occasioned by a white film growing over their eyes, in consequence of some sort of inflammation, as arising from different causes, taking place in them.

The appearances by which it is shewn to be present are, according to some, that the animal cannot bear the light, that the white part of the eye is red and inflamed, and that it waters a great deal. That this state is succeeded by a sort of membrane or coat formed by the inflamed vessels, which first covers the white, but gradually extends over the eye, until total blindness is the consequence. That this is noticed to be the case, when in folding, the sheep run against dykes, or any other such obstacles, and start when they approach them; that they do not follow the flock, and that they frequently stumble. That when the eye is inspected, it is ge-

nerally found, that a blue slough covers the whole of the eye, without any intermixture of red vessels. That in the worst cases, the coloured and transparent part of the eye becomes of a reddish-white; by which time, the film on the eye has acquired considerable thickness and hardness. That the inflammation is produced in various ways, and by various means; as during the summer season by the reflection of heat and light in very sunny and dry weather, as it is found to be more frequent when the hilly sheep-walks become scorched, and on hard rocky soils, than on the dark-coloured hills which are covered with heather. Others suppose, that the disease is sometimes caused by the pollen or dust of flowers irritating the eyes of the sheep, when blown into them, in considerable quantities, by the wind. That in the winter, the blindness is caused and occurs when the days are very sunny, and the evenings frosty and cold; or when the sheep have been long buried under snow, and the ground is still white and glaring when they get out.

But by still others, the blindness in sheep is believed to arise from a cause wholly different from any of these. That it is induced by a continued fatigue for a length of time, which is capable of bringing it on at any season of the year. Thus, sheep that are long and hard driven, or such as are daily dragged from one part of the ground to another, ewes that are *cild*, or old, and roughly handled and used by the women in milking, during the operation, where that practice is in use, and hog-sheep which are tired by driving through snow, in order to preserve their subsistence, are all liable to this affection of the eyes. That their eyes at first become sore, and emit a sort of rosy humour; after which a white film settles over them, and if they continue to be fatigued, it grows thicker, the eyes appearing perfectly white; in which cases, they are said to be proportionably longer in getting better. The disease, too, may proceed from many other causes of different kinds, as all such as tend to cause local inflammation in the parts, as cold, moisture, and many others of the same sort.

In the cure of the disease, where it is suspected to arise from the irritating powdery matter of flowers, the sheep should be immediately removed to other proper pastures for a time, until the danger from that cause is over; and in cases of snow-blindness of this kind, it is always proper to bring them down, as soon as possible, from the high snowy walks, where they occupy them, to the bare grounds below.

The inflamed vessels on the white of the eye, especially those next the nose, are also sometimes advised to be cut with a lancet or sharp penknife every second morning; while the eyes are to be kept defended against the light, by a shade tied over the head, or a piece of crape over the eyes. The eyes may likewise be bathed two or three times a-day, with a solution of half a drachm of sugar of lead, or of two drachms of alum, and the same quantity of white vitriol, in a pint of soft-water. At the same time purgatives may be given internally, such as two ounces of some purging salts, or, what is better, a scruple of calomel, once a day for four or five times. When, by these means, the inflammation is got the better of, but the slough still remains, a little ointment, composed of eight parts of some mild unctuous substance, and one of red precipitate of mercury, made fine by rubbing, may be insinuated into the eyes every morning; or a little finely powdered crystal and loaf sugar be blown into them twice in the day.

With some, it is at first the practice to bleed the sheep below the eyes, and to let some of the blood run into each of them; but it is supposed that care will infallibly cure the disease in a space of time proportioned to the debility that has

has induced the complaint without any thing else. The best and most proper means of cure in these cases are, in the first place, local or general bleeding, then the use of some such solutions and internal remedies as the above, after some time having recourse to stronger washes and powders of the same nature, with small quantities of opium, and keeping the animals all the while as much as possible from the light, and the glare of the ground. (See a paper in the third volume of the Transactions of the Highland Society of Scotland.) It is observed, that certain parcels of sheep are very liable to blindness of this sort, and that although it is not a fatal disease in itself, it frequently occasions considerable loss by the sheep drowning themselves, or breaking their necks in falling down precipices and other such places.

WHITE Flag, Flake, and Frost. See the substantives.

WHITE Foot, in the *Manege*, called in French *balzana*, is a white mark that happens in the feet of a great many horses, both before and behind, from the fetlock to the coffin. The horses thus marked are either tramelled, cross-tramelled, or white all four. Some horsemen place an unlucky fatality in the white of the far foot behind. See *CHAUSSE' Trop haut*, and *TRAMELLED*.

WHITE Friars, a name common to several orders of monks, from their being clothed in a white habit.

Such are, the regular canons of St. Augustine, the Premonstratenses, and Bernardines. See *CARMELITES*.

WHITE Glass. See *GLASS*.

WHITE-Hart Silver, candidi cervi argentum, a tribute or mulct paid into the exchequer, out of certain lands in or near the forest of White-hart, in Dorsetshire; which was continued from Henry III.'s time, who first imposed it upon Thomas de la Linde, and others, for killing a beautiful white hart, which that king had purposely spared in hunting.

WHITE Hellebore. See *HELLEBORE*.

WHITE Honeysuckle, in *Agriculture*, a term often applied to the white clover. It is stated, in the Agricultural Report for the County of Gloucester, to be a plant which is brought forward by manure and sheep-stock, and a proof of good land, at least of land in a high state of cultivation; and that, on this account, it has, when it abounds in dairy pastures, a tendency to raise the quality of the milk, and make the cheese more or heavier which is made from it. See *DAIRYING*, and *WHITE Clover*.

WHITE Horse-Fish, in *Ichthyology*, a common English name for the *raia aspera* nostras of Willughby, and the *raia fullonica* of Rondeletius and Linnæus. Its back is rough and spiny; the nose is short and sharp; at the corner of each eye are a few spines; the nictitating membrane is fringed; the teeth are small and sharp: on the upper part of the pectoral fins are three rows of spines pointing toward the back, and crooked, like those of the fuller's instrument; whence its name *fullonica* and *fuller*. On the tail are three rows of strong spines: the tail is slender, and rather longer than the body. The colour of the upper part of the body is cinereous, usually marked with many black spots; the lower part white. This fish grows to a size equal to that of the skate. Pennant.

WHITE Jasper, in *Mineralogy*, or agate jasper, has a pale yellowish-white colour, and sometimes occurs reddish-white. It is opaque, and has small imperfectly conchoidal fractures. See *JASPER*.

WHITE Land, in *Agriculture*, a tough clayey soil, naturally of a somewhat whitish hue when dry, especially when it has lain some time untilled, but becoming blackish after rain: this appears of a light greyish colour when turned up by the plough, and slides off from the plough-share with

ease, and with a smooth glossy surface. It has often a yellowish hue with the grey, and is often veined with large parcels of a blue marly earth. See *Clay SOIL*.

WHITE Lead is a sort of rust of lead, or lead dissolved with vinegar; much used by painters. See *LEAD*, and *CERUSE*.

WHITE Leaf. See *CRATÆGUS*.

WHITE Line, among *Printers*, a void space, greater than usual, left between two lines. See *PRINTING*.

WHITE Line, in *Anatomy*. See *LINEA Alba*.

WHITE Linnen is cloth of hemp, or flax, bleached by divers leys, and waterings on the ground.

WHITE Manganese, in *Mineralogy*, manganese oxydè carbonaté, Haüy. Red manganese ore of some mineralogists. This ore occurs of various colours, from yellowish-white to rose-red. See *Ores of MANGANESE*.

WHITE Meats include milk, butter, cheese, white pots, custards, and other foods consisting of milk, or eggs. Some add, also, fish, veal, and chickens.

WHITE Mortar. See *MORTAR*.

WHITE Must-Apple, in *Rural Economy*, a very fine cider-fruit in field fruit-grounds. This, with the fox-whelp, red-streak, and some others, are fine old fruits, but which are now going off, and afford the best cider, when mixed in the mill: the proportions in which they are to be used have never, however, been defined, but depend probably a good deal on the quantity to be ground at the same time.

WHITE Mustard, in *Agriculture*, a sort of plant which is often cultivated in the field for the use of the seed in different places.

The best sort of soil for it is that of the light loam, which should be well broken down and reduced by ploughing and harrowing. Some, on fresh broken up land, make a winter fallow for this crop.

It is mostly put in after a wheat-crop, but may succeed others where the land is clean and well prepared. In Kent, they strike furrows about eleven or twelve inches apart, and then sow the seed, two or three gallons to the acre, in the month of March.

The culture of it while growing is to hoe it, and keep it free from weeds, to set it out in the way of turnips, not too thick on the ground, as that draws up the plants weak. The crop is reaped about July. In some cases, it is laid in gavels or handfuls upon the stubble, in the same manner as cole-seed. It is usually threshed out on a sail-cloth in the field.

The produce differs from eight to twenty bushels the acre.

It is a ticklish sort of crop, as one frosty morning will kill it, and it is liable to be injured and eaten by the black caterpillar; but when it turns out well is very profitable.

It is said not to exhaust the land much, which is greatly in its favour.

WHITE Nebbed-Crow, a term provincially applied to the rook in some cases.

WHITE Order. See *ORDER*.

WHITE Paper is that intended for writing, printing, &c. in contradistinction to *brown paper*, *marbled paper*, *blotting paper*, &c.

WHITE, Pearl. See *PEARL*.

WHITE Pepper. See *PEPPER*.

WHITE Poplar, in *Agriculture*, a tree of the poplar kind, in which the wood is soft, but convertible to various uses in husbandry, as it grows quickly and bears cropping well. It is best grown in low situations, where the soil is of a clayey nature. It is sometimes called the abele tree.

WHITE Poppy, a plant sometimes cultivated in the garden and the field for the use of the opium which is obtained from its juice by means of evaporation. It might be largely cultivated in many situations with great advantage, as it contains this substance or principle in great abundance. See *PAPAVER Album*.

WHITE Porcelain. See *PORCELAIN*.

WHITE Pot, denotes milk or cream baked with the yolks of eggs, fine bread, sugar, and spice, in an earthen pot.

The cooks furnish us with a variety of dishes under this form and denomination: such are, Norfolk white-pot, Westminster white-pot, rice white-pot, &c.

WHITE Pottery. See *POTTERY*.

WHITE Precipitate. See *Carbonate of MERCURY*.

WHITE Pyrites, in *Mineralogy*; Fr. *sulfuré blanc*, Haüy. The colour of this ore when pure is of a tin-white colour, passing into brass-yellow and steel-grey. It occurs in small octohedral crystals variously modified, also stalactitical and botryoidal. It is hard, brittle, and easily frangible. It melts before the blow-pipe, giving out a sulphureous vapour; it then acts on the magnetic needle. It decomposes much easier than common pyrites. It contains 46 parts of iron and 54 of sulphur. See *PYRITES*.

WHITE Rent, in *Rural Economy*, a rent or duty of 8d. payable yearly, by every tinner in the counties of Devon and Cornwall, to the duke of the latter, as lord of the soil. See *BLANCH Fermè*.

WHITE Salt is common or sea-salt dried and calcined by the fire, so as not to leave any moisture therein. The chemists call it *decrepitated salt*.

There are some salts naturally white, and others that need to be whitened, either by dissolving and purifying them in fair water, which is afterwards evaporated; or by means of fire; or by the sun. See *SALT*.

WHITE Salt, a term applied to the fine purified salt, in contradistinction to that of the rock kind. The former is said in Cheshire to form a much more important object in the way of commerce than the latter. See *SALT*.

WHITE Sauce, a sort of sauce made of blanched almonds, and the breast of a capon, pounded together with cloves, cinnamon, &c. We also hear of white broth, which is a sort of broth enriched with sack and spices, having blanched almonds scraped into it, and the whole thickened with the yolks of eggs, &c.

WHITE Scour. See *SCOUR*.

WHITE Silver Ore, in *Mineralogy*, an ore of silver always associated with lead and antimony. (See *SILVER Ores*.) Dark white silver contains, according to Klaproth, 9.25 parts in the hundred of silver. Light white silver ore contains 20.40, associated with the same minerals as the dark ore, but in different proportions.

WHITE Soap. See *SOAP*.

WHITE, *Spanish*, is a kind of fucus used by the ladies to whiten their complexion, and hide the defects of it, called also *magistery of bismuth*.

The use of this, as well as of cerusses, is pernicious; and should be particularly avoided during the taking of any sulphureous water, which may change the complexion quite black. Indeed, all phlogistic vapours, and even the sun itself, tend to give both the magistery of bismuth and cerusse a yellow colour: an observation which serves to explain a passage in Martial, where a cerused lady is said to fear the sun.

“Cretata timet Fabulla, nimum,
Cerufata timet Sabella, solem.

Ep. lib. ii. Ep. 41.

WHITE, *Spanish*, is also a name given to troy white.

WHITE Spurs. See *SPUR*, and *ESQUIRE*.

WHITE Star, and *Sugar*. See the substantives.

WHITE Stone, in *Geology*; *Weiss stein*, Werner; *Eurite* of some French geologists; a rock enumerated by Werner as a distinct species among the primary rocks. It is essentially composed of felspar, but contains mica and other minerals. We think it may fairly be doubted whether white-stone ought to be considered as a distinct species of rock, or only as an occasional mode in which gneiss and granite sometimes occur. According to the account given by M. Bonnard of the Saxon Erzgerberge, in the *Journal des Mines*, 1815, the gneiss of that district often loses its mica, and passes into a rock essentially the same as white-stone or eurite. In other instances, the granite, by losing a great part of its mica and quartz, passes into the same rock, still retaining the geological position of granite, and including immense beds of granite within it. The north-western acclivity of the Saxon Erzgerberge is almost entirely composed of white-stone, including masses of granite, from a few feet to some miles in extent. This rock forms the basis on which the other rocks are placed. Bonnard gives the following description of white-stone or eurite in the above district:—It is composed of very fine granular felspar, which is sometimes compact, of a whitish-grey or yellowish-grey colour; the mica is brownish. It occurs in layers, and is sometimes fissile when the mica is abundant. In this case, the felspar is almost as friable as dolomite. When the felspar is compact, and the mica more rare, the rock nearly loses its fissile property. This rock contains fappare and other minerals disseminated. The rock on which it rests is unknown, as the white-stone serves as a basis for the gneiss and other rocks. In the greater part of the district a granitic rock occurs in the white-stone, which is sometimes a true granite and sometimes a granular eurite. This granite is composed of felspar, which is rarely of a red colour, but often brown, which is also generally the colour of the mica; the proportion of the quartz is variable, and sometimes is entirely wanting. In the few places where the two rocks can be seen together, the granite appears not only to alternate with the eurite, but to pass into it; or rather the two rocks may be said to pass insensibly into each other, both in the small and large masses. The grain of the granite is often very fine; but near Penig it contains crystals of felspar of a foot in cubic size. The only beds which occur in the white-stone are of serpentine; these are in the upper part of it, and dip to the north. There have been no metallic veins discovered in the white-stone rock. From the above description, there can be little doubt that white-stone ought, when viewed geologically on a large scale, to be considered only as a particular form of granite arising from the diminution of the quartz and mica. The circumstances, whatever they may have been, which first disposed the granite to solidify, permitted the constituent parts to arrange themselves in different proportions in various parts of the mass. Thus in extensive granite formations, nothing is more frequent than to see the quartz and felspar collected in large masses nearly pure, or with a very small admixture of the other component parts; and in the white-stone of Saxony precisely the same facts are exhibited on a larger scale. See *ROCKS, STRATA, and SYSTEMS of Geology*.

WHITE Styre Apple, in *Rural Economy*, a rich cider-fruit in field orchards. It is said to be the boast of the forest district in Gloucestershire, and that under proper management, it affords a cider so rich and strong, that it is often valued equally with foreign wine, and sold at extravagant prices.

WHITE-SWELLING.

WHITE-Swelling, in Surgery. When a disease is attended with great varieties, not only with regard to its progress and symptoms, but also its cause, and the disorder which it produces in the parts which are the seat of it, there is as much difficulty in fixing upon a name that will convey an exact idea of it, as in offering a definition or description of it applicable to all the cases which may present themselves to the attentive observer. Such are the circumstances of the disease of which we are about to speak in the present article. Surgeons have given it a variety of appellations, derived from some one particular symptom with which it is accompanied. Thus, it has been called *white-swelling*, (a name which is still most generally adopted,) because the skin which covers it retains its natural colour, and exhibits no appearance of inflammation. It is also sometimes termed *fungus articuli*, on account of its softness and elasticity, which allow it readily to yield to pressure, but make it rise up again immediately when the compression is discontinued, like the fungous excrescences which grow upon the oak. The disorder is likewise often named by foreign writers the *lymphatic tumour*, or *serous swelling of the articulations*, in consequence of the great quantity of thick lymph which appears to be effused in the cellular substance around the ligaments, and upon the ligaments themselves. Sometimes the disease is called *spina ventosa*. (See that article.) The case is occasionally denominated a *false ankylosis*, because the disease causes more or less interruption of the motions of the joint. Lastly, the distemper is often called a *rheumatic*, or *serofulous disease of a joint*, according as rheumatism, or scrofula, is suspected of being concerned in its origin.

White-swellings are usually defined to be chronic enlargements of the joints; circumscribed; without any alteration in the colour of the skin; sometimes hard, and resisting the pressure of the fingers; sometimes less firm, elastic, yielding to pressure, and afterwards rising up again in the manner of a fungus, which grows upon certain trees; sometimes so soft as to present a deceitful feel of fluctuation, although there is no fluid in the part. In particular instances, these swellings are indolent; but, most frequently, they are attended with great pain, especially when the joint is moved, so that the patient either cannot exercise the limb at all, or does it at the expence of considerable suffering, and with imperfection and difficulty. The disease has its seat in the ligaments, cellular substance, synovial glands, cartilages, and even the bones. All these parts, however, are not affected in every instance; and sometimes the distemper commences in the bones; sometimes in the cartilages and ligaments, according to the peculiarity in the nature of the case. The foregoing definition is obviously merely an enumeration of the principal symptoms of white-swellings, and is far from giving an exact idea of a disease which presents so many varieties in different individuals, that there are scarcely two patients to be met with in whom the complaint follows precisely the same course, or exhibits altogether similar phenomena.

There is no joint which may not be attacked by this inveterate disease; but experience proves, that the ginglymoid articulations are more frequently affected than the orbicular. We are, however, to except from this remark the articulation between the femur and os innominatum, in which the disease is very common, and often called by the French surgeons *spontaneous dislocation of the femur*, because the case generally terminates in a displacement of the head of the thigh-bone. (See *HIP-Joint, Disease of*.) Amongst the ginglymoid joints, the knee is oftener affected than any other. Then come the joints of the elbow, foot, and hand. White-

swellings attack the small joints, like those of the fingers and toes, with far less frequency.

White-swellings may occur at every period of life; but they are more common in infancy and youth than in adults and old subjects. It is conceived also by some writers, that these cases begin more frequently in autumn and winter, or when the atmosphere is damp and variable, than in the other seasons. But the disease is on the whole so common in this climate, that it must be difficult to establish the truth of the foregoing conjecture.

The disease sometimes begins with a more or less acute pain in the articulation, usually extending along the fasciæ and tendons of the neighbouring muscles. Sometimes the pain is of a dull kind, being superficial, seated in the soft parts, and reaching all round the joint. On other occasions, it is acute, deeply situated, and confined to a small space, which is mostly the very centre of the articulation. In particular examples, the swelling of the joint succeeds a pain which has been experienced in another part of the body, and suddenly ceased. Sometimes the disease begins in so unexpected a manner, that the patient, who went to bed perfectly well, rises in the morning with a stiff painful knee. Cases of the latter kind are generally rheumatic.

Whatever may be the manner in which the complaint originates, and whatever the circumstances which precede the attack, it always comes on in the form of a tumour, which presents the following characters:—The swelling seldom reaches all round the articulation; but is almost always limited to a more or less extensive portion of the circumference of the part. In the knee, it occurs above the patella, and also below this bone, at the sides of the ligament, which connects it with the tibia. In the elbow, it chiefly occupies the sides of the joint, especially the inner side. In the ankle, it takes place below and behind the malleoli. Lastly, in the fingers, it commonly affects the whole circumference of the diseased joint. Such swelling is circumscribed, immoveable, and more or less hard and elastic, not retaining the impression of the finger, as in œdema (see **ŒDEMA**), but generally communicating, when handled, a sensation of softness, which leads to a suspicion of the presence of a fluid, when none in reality exists. The swelling is more or less painful, especially when compressed. Sometimes, however, it is indolent; the heat of the part is not increased, and the integuments continue of their natural colour. The motion of the joint is impeded, and if the patient will not abstain from moving the part, he is put to excruciating pain. There are some white-swellings of the knee, in which the leg is fixed in the extended posture; but, most commonly, the limb is bent, even in a considerable degree, and when an endeavour is made to straighten it, great suffering is excited. In white-swellings of the elbow, the fore-arm is constantly observed in a state of flexion. In those of the wrist, the hand has a strong propensity to fall into the bent position; and in order to prevent this occurrence, and hinder an incomplete luxation of the carpus from taking place backwards, the surgeon is sometimes obliged to support the hand upon a splint.

The constant flexion of the limb produces a considerable retraction of the flexor muscles and their tendons, together with a rigidity which can be felt through the integuments, which are raised up by the sinews so affected. The total loss of exercise always arising from this state of the muscles and tendons, generally soon renders the joint stiff and motionless, so that it frequently has the appearance of being in a state of real and complete ankylosis. See **ANKYLOSIS**.

WHITE-SWELLING.

The swelling may remain a long while in the condition which has been described; it may even cease to be painful; and it may cause only a serious weakness of the knee, and more or less difficulty in walking. But most commonly it continues to make uninterrupted progress; or, if its advances should happen to be checked, and the disease be for a time stationary, it frequently occurs, that, in consequence of a fall, a bruise, or even without any external cause, and, as it were spontaneously, the complaint afterwards increases again. The articulation swells more and more, and, if it be the knee which is affected, the hollow of the ham also swells up and becomes effaced. The pain likewise augments, being felt sometimes at one point of the circumference of the joint, sometimes at another; occasionally in the ham, and, in other examples, in the very cavity of the articulation. There are, however, some patients who seem to suffer little or no pain of any consequence. The hardness of the tumour is subject to great variety. The older the disease is, the more considerable is in general the degree of induration. Yet there are certain white-swellings which are extremely hard, although they have not existed a long while; and other cases which are very soft, notwithstanding they are of long standing. Boyer thinks, that this difference depends upon the seat of the disease, which is sometimes in the bones; sometimes in the ligaments and surrounding cellular membrane. The skin which covers the swelling grows thin, pale, and shining; the cutaneous veins become dilated and varicose; and the muscles of the leg waste and dwindle away, so that the size of this part of the limb is strikingly diminished. Sometimes, however, it is affected with œdema, and has the appearance of being enlarged. The lower part of the thigh also frequently undergoes a very considerable diminution. This wasting of the limb above and below the disease, makes the joint also seem much more swelled than it is in reality. Sometimes the lymphatic glands in the groin become enlarged and hardened; and when the disease makes much progress, the bones are frequently softened and carious, and the cartilages destroyed. Lastly, abscesses, more or less considerable, are formed in different parts of the tumour; and their formation is attended with a great deal of acute pain, inflammation, and fever. These abscesses are more or less deeply situated, and often communicate with the interior of the joint. When they burst, or are opened, a large quantity of matter is discharged, which is hardly ever of healthy consistence, being mostly a sero-purulent yellowish fluid, somewhat resembling turbid whey, and containing flakes of albumen. Sometimes, however, it presents very nearly the appearances of healthy pus; but it soon changes into a thin fetid sanies of very bad quality. Its discharge, although very considerable, is followed by scarcely any perceptible diminution in the size of the swelling. The openings by which it escapes sometimes soon close, and fresh collections of matter ensue which burst of themselves, and then heal up like the former; but, in general, the apertures, instead of healing, become converted into incurable fistulæ.

Mr. Brodie has paid considerable attention to the several diseases of the joints, which usually go under the name of white-swelling. In particular, he has carefully examined the morbid appearances which are found upon dissection; and his observations have led him to propose a classification of these diseases.

1. The first case which Mr. Brodie describes is, *inflammation of the synovial membrane*, which may occur as a symptom of a constitutional disease, where the system is affected with rheumatism; where mercury has been improperly exhibited, or in large quantities; or where there is general debility

from any other cause. But, in these cases, the inflammation is seldom severe; it occasions an effusion of fluid into the joint, but rarely terminates in the extravasation of coagulating lymph, or thickening of the inflamed membrane. Sometimes it leaves one joint to attack another; or, it suddenly subsides without another joint becoming affected.

At other times, says Mr. Brodie, the inflammation occurs as a local affection produced by a sprain, the application of cold, or arising from no evident cause. It is then, for the most part, more severe, and of longer duration; it leaves the joint with its functions more or less impaired, and occasionally terminates in its total destruction. In itself, it is a serious disease; but it is often confounded, under the general name of white-swelling, with other diseases still more serious. In some cases, it assumes the form of an acute; but in the greater number of instances, it has that of a chronic inflammation.

When the case is acute, the skin is in general red, and the joint tender and painful. The pain, which is not confined to any particular point, and aggravated by motion of the limb, is soon followed by swelling. The patient is also affected with inflammatory fever. In a few days, the disease either subsides altogether, or assumes the chronic form.

According to Mr. Brodie, when the inflammation is chronic, the pain and tenderness are less, so that the patient is able to walk about, and often without experiencing any severe distress. There is no fever, and the skin retains its natural colour. The swelling also increases less rapidly than in acute cases. These symptoms are generally rendered worse by exposure to cold and exertions. In the first instance, the swelling of the joint arises entirely from a preternatural quantity of synovia. But when the inflammation has existed some time, the fluid is not so plainly perceptible, because the synovial membrane is now thickened, which likewise augments the stiffness of the articulation. The shape of the swelling is not that of the articulating ends of the bones, but arises chiefly from the distended state of the synovial membrane, and hence depends in a great measure on the situation of the ligaments and tendons, which resist it in certain directions. Thus, when the knee is affected, the swelling is principally observable in the same places where it occurs in cases of hydroys articuli.

After the inflammation of the synovial membrane has subsided, the fluid is absorbed, and, in some instances, the joint recovers its natural figure and mobility; but in the majority of cases, the stiffness and swelling continue. Whenever the patient is exposed to cold, or exercises the limb much, the pain returns, and the swelling is increased. Such cases are of frequent occurrence, and, as Mr. Brodie observes, they form a large proportion of those diseases which are called white-swellings.

Long-continued and neglected inflammation of the synovial membrane sometimes terminates in the formation of an abscess in the joint, in ulceration of the cartilages, and destruction of the articular surfaces. *Medico-Chir. Transf. vol. v. p. 240, &c.*

2. The same gentleman has favoured the public with a very circumstantial history of another description of cases, where the disease originates in the synovial membrane, which loses its natural organization, and becomes converted into a thick pulpy substance of a light brown colour, intersected by white membranous lines, and from one-fourth to one-half of an inch, or more, in thickness. As this disease advances, it involves all the parts of which the joint is composed, producing ulceration of the cartilages, caries of the bones,

bones, wasting of the ligaments, and abscesses in different places. The complaint has invariably proved slow in its progress, and sometimes has remained nearly in an indolent state for many months, or even for one or two years; but Mr. Brodie informs us, that he has never met with an instance in which a real amendment was produced, much less a cure. (See *Medico-Chir. Transf.* vol. iv. p. 220, &c.) Mr. Brodie also remarks, that the above-described affection of the synovial membrane is rarely met with, except in the knee, and that it generally takes place in young persons under, or not much above the age of puberty. In the origin of this disease, there is a slight degree of stiffness and tumefaction, without pain, and producing only the most trifling inconvenience. These symptoms gradually increase, so that, at last, the joint scarcely admits of the smallest motion, the stiffness being greater than what is the usual result of common inflammation. The form of the swelling bears some resemblance to that in cases of inflammation of the synovial membrane; but it is less regular. The swelling is soft and elastic, and gives to the hand a sensation as if it contained fluid. If only one hand be employed in making the examination, the deception may be complete, and the most experienced surgeon may be led to suppose that there is fluid in the joint when there is none; but if both hands be employed, one on each side, the absence of fluid is distinguished by the want of fluctuation.

“The patient experiences little or no pain, until abscesses begin to form, and the cartilages ulcerate; and even then the pain is not so severe as where the ulceration of the cartilages occurs as a primary disease, and the abscesses heal more readily, and discharge a smaller quantity of pus than in cases of this last description. At this period, the patient becomes affected with hectic fever, loses his flesh, and gradually sinks, unless the limb be removed by an operation.” See Brodie’s *Obs. in Medico-Chir. Transf.* vol. v. p. 251, &c.

3. Another form of white-swelling described by the same writer, is that which is more particularly characterized by ulceration of the articular cartilages. This change occurs in the advanced stage of several diseases of the joints, and it also exists in many instances as a primary affection, in the early stage of which the bones, synovial membrane, and ligaments, are in a natural state; but which, if neglected, ultimately occasions the entire destruction of the articulation. When ulceration of the cartilages occurs in the superficial joints, it constitutes one of the diseases which have been known by the name of white-swelling. From cases which Mr. Brodie has seen, he is led to conclude, that when it takes place in the hip it is this disease, which has been variously designated by writers, the “*morbus coxarius*,” the “*disease of the hip-joint*,” the “*scrofulous hip*,” the “*scrofulous caries of the hip-joint*,” &c. At least, Mr. Brodie conceives, that it is to this disease such names have been principally applied, though he acknowledges that there are probably other morbid affections which have been confounded with it. (*Op. Cit.* vol. iv. p. 236.) The ulceration of the articular cartilages takes place as a primary disease, chiefly in children or adults under the middle age. “Of sixty-eight persons affected with this disease, fifty-six (according to Mr. Brodie) were under thirty years of age: the youngest was an infant of about twelve months; the oldest was a woman of sixty.” As the knee is more frequently affected with inflammation of the synovial membrane, so is the hip more liable than other joints to ulceration of the cartilaginous surfaces. In general, the disease is confined to a single joint; but it is not very unusual to find two or three joints

affected in the same individual, either at the same time or in succession. Sometimes the patient traces the beginning of his symptoms to a local injury, or to his having been exposed to cold; but, for the most part, no cause can be assigned for the complaint. See *Medico-Chir. Transf.* vol. vi. p. 319.

For a description of the disorder as it occurs in the hip, the reader is referred to the article *HIP-Joint, Disease of*. At present, we shall merely notice the symptoms which, according to the investigations of Mr. Brodie, particularly characterize ulceration of the cartilages of the knee. They differ from the symptoms of inflammation of the synovial membrane, by the pain being slight in the beginning, and gradually becoming very intense, which is the reverse of what happens in the latter affection. The pain also in the commencement is unattended with any evident swelling, which never comes on in less than four or five weeks, and often not till after several months. It is not to be inferred, however, that every slight pain of the joint unaccompanied with swelling, must of course arise from ulceration of the cartilages. But, says Mr. Brodie, when the pain continues to increase, and at last is very severe; when it is aggravated by the motion of the bones on each other; and when, after a time, a slight tumefaction of the joint takes place, we may conclude that the disease consists in such ulceration. The swelling arises from a slight inflammation of the cellular membrane on the outside of the joint; it has the form of the articulating ends of the bones; and for the most part it appears greater than it really is, in consequence of the muscles being wasted. No fluctuation is perceptible, as where the synovial membrane is inflamed; nor is there the peculiar elasticity, which exists, where the synovial membrane has undergone a morbid alteration of its structure.

Mr. Brodie, however, has explained, that, in some cases, the swelling has a different shape, and communicates the feel of a fluctuation. This happens when inflammation of the synovial membrane, attended with a collection of the synovia of the joint, or abscesses in the surrounding soft parts, or in the articulation itself, occur as secondary diseases. When there has been considerable destruction of the soft parts from abscesses and ulceration, the head of the tibia may become dislocated and drawn towards the ham. See *Medico-Chir. Transf.* vol. vi. p. 326, &c.

4. There is another species of white-swelling which is peculiarly different from others, in being attended with ulceration of the synovial membrane. As, however, it does not appear to us to need a description in a work not expressly devoted to surgery, we shall only add, that the reader may find Mr. Brodie’s account of the case in the *Medico-Chir. Transactions*. Those white-swellings which are reputed to be scrofulous, form a subject, however, on which we cannot be silent. In the scrofulous diseases of the joints, the bones are primarily affected, in consequence of which ulceration takes place in the cartilages covering their articular surfaces. The cartilages being ulcerated, the subsequent progress of the disease is, according to Mr. Brodie, the same as where this ulceration takes place in the first instance.

It has been a very prevalent opinion, that, in cases of white-swelling, the heads of the bones are always enlarged. Mr. Russell is, perhaps, the first writer who expressed an opposite sentiment, and he absolutely declares, that he had never heard nor known of an instance, in which the tibia was enlarged from an attack of white-swelling. (*On Diseases of the Knee*, p. 37.) We believe, that a regular expansion
of

WHITE-SWELLING.

of the heads of the bones, in cases of white-swelling, is far from being an usual occurrence, although it may sometimes happen. It is frequent, however, to meet with a sort of enlargement, which arises from spiculæ of bony matter, deposited on the outside of the tibia, ulna, &c., which alteration is materially different from a regular expansion of the heads of those bones. We have, however, lately seen an instance, in which the upper head of the ulna is considerably increased in size by a regular kind of expansion. The preparation is in Mr. Abernethy's museum; and a few other specimens have, we believe, been occasionally noticed. Yet, as a general fact, we may still remark, that an enlargement of the heads of the bones in the diseases called white-swelling, is far from being the usual state of things. The change which the head of the tibia undergoes in many cases, is first a partial absorption of the phosphate of lime throughout its texture, while a soft kind of matter is secreted into its substance. In a more advanced stage, and, indeed, in that stage which most frequently takes place before the limb is amputated, there are deep excavations in the head of the bone, arising from caries, and its structure is now so softened, that when a probe is pressed against the carious part, it readily penetrates deeply into the bone.

Mr. Brodie also joins in the opinion, that the morbid affection has its origin in the bones, "which," he says, "become preternaturally vascular, and contain a less than usual quantity of earth, while, at first, a transparent fluid, and afterwards a yellowish cheesy substance, is deposited in their cancelli. From the diseased bone, vessels, carrying red blood, shoot into the cartilage, which afterwards ulcerates in spots, the ulceration beginning on that surface which is connected to the bone." *Med. Chir. Transf. vol. iv. p. 272.*

With respect to the expansion of the heads of the bones, we ought to have mentioned, that the late Mr. Crowther entirely disbelieved the reality of the occurrence, and every body knows, that he paid very considerable attention to the subject. (See *Pract. Obs. on White-Swelling, &c. edit. 2. p. 14.*) The event, however, should have been described as unusual, and not as never happening, since, as we have already stated, a few specimens of such a change have now been collected.

Mr. Russell has particularly noticed how much the soft parts frequently contribute to the swelling: "the great mass of the swelling," he observes, "appears to arise from an affection of the parts exterior to the cavity of the joint, and which, besides an enlargement in size, seem also to have undergone a material change in structure. There is a larger than natural proportion of a viscid fluid, intermixed with the cellular substance; and the cellular substance itself has become thicker, softer, and of a less firm consistence than in a state of health." (*On the Morbid Affections of the Knee, p. 30.*) The manner in which the soft parts are affected is also described by Mr. Brodie. "Inflammation takes place of the cellular membrane, external to the joint. Serum, and afterwards coagulable lymph, are effused; and hence arises a puffy elastic swelling in the early and an œdematous swelling in an advanced stage of the disease. Scrofula attacks only those bones, or portions of bones, which have a spongy texture, as the extremities of the cylindrical bones, and the bones of the carpus and tarsus; and hence the joints become affected from their contiguity to the parts which are the original seat of the disease." *Med. Chir. Transf. vol. iv. p. 273.*

All white-swellings which make considerable progress, and occasion severe pain, long confinement, abscesses, &c.

unavoidably bring on that impairment of the general health, which is well known by the name of hectic fever. The patient gradually loses his appetite and natural rest and sleep; his pulse is small and frequent; an obstinate debilitating diarrhœa, and profuse nocturnal sweats, ensue. Such complaints are sooner or later followed by dissolution, unless the constitution be relieved in time, either by the amendment or removal of the diseased part. In different patients, however, the course of the disease, and its effects upon the system, vary considerably in relation to the rapidity with which they occur.

Rheumatic white-swellings are very distinct diseases from the scrofulous distemper of the large joints. In the first, the pain is said never to occur without being attended with swelling. Scrofulous white-swellings, on the other hand, are always preceded by a pain, which is particularly confined to one point of the articulation. In rheumatic cases, the pain is more general and diffused over the whole joint.

It seems probable, that all cases in which the structure of the bones is found quite undiseased, and in which all the marks of disease appears to be confined to the soft parts, are not scrofulous white-swellings. Few persons who have attained the age of five-and-twenty, without having had the least symptom of scrofula, ever experience, after this period of life, a first attack of the white-swelling of the stumous kind. All cases, in which the internal structure of the heads of the bones becomes softened, are probably scrofulous.

Mr. Russell has noticed the frequent enlargement of the lymphatic glands in the groin, in consequence of the irritation of the disease when in the knee; but, he justly adds, that this secondary affection never proves long troublesome.

When the bones are diseased, the head of the tibia always suffers more than the condyles of the thigh-bone. (*Russell.*) The articular surface of the femur sometimes has not a single rough or carious point, notwithstanding that of the tibia may have suffered a great deal. The cartilaginous coverings of the heads of the bones are generally eroded first at their edges; and in the knee, the cartilage of the tibia is always more affected than that covering the condyles of the thigh-bone. Indeed, when white-swellings have their origin in the bones, and the knee is the seat of the disorder, there is some ground for supposing that it is in the tibia that the morbid mischief first commences.

The ligaments of the knee are occasionally so much weakened or destroyed by this terrible malady, that the tibia and fibula become more or less dislocated backward, and drawn towards the tuberosity of the ischium, by the powerful action of the flexor muscles of the leg.

We have seen a curious species of white-swelling, in which the leg could be moved to each side a very considerable distance, both when the knee was extended and bent. Such a state implies a preternatural looseness of the ligaments of the articulation.

Scrofulous white-swellings, no doubt, are under the influence of a particular kind of constitution, termed a scrofulous or stumous habit. In this sort of temperament, every cause capable of exciting inflammation, or any morbid and irritable state of a large joint, may bring on such disorder as may end in the severe disease of which we are now speaking.

In a man of a sound constitution, an irritation of the kind alluded to might only induce common healthy inflammation of the affected joint.

In scrofulous habits, it also seems probable, that irritation

tion of a joint is much more easily produced than in other constitutions; and no one can doubt, that when once excited in the former class of subjects, it is much more dangerous and difficult of removal than in other patients.

The doctrine of particular white-swellings being scrofulous diseases, is supported by many weighty reasons, the opinions of the most accurate observers, and the evidence of daily experience. Wiseman (book iv. ch. 4.) calls the *spina ventosa* a species of scrofula, and tells us, that infants and children are generally the subjects of this disease. The disorder is said by Severinus to be exceedingly frequent in young subjects. Petrus de Marchettis has observed both male and female subjects affected with what are called strumous diseases of the joints, as late as the age of five-and-twenty; but not afterwards, unless they had suffered from scrofula before that period of life, and had not been completely cured. R. Lowerus also entertains a similar opinion. Even though a few persons may have scrofulous diseases of the joints, for the first time, after the age of twenty-five, this occurrence, like the first attack of scrofula after this period, must be considered as extremely uncommon.

Another argument in favour of the doctrine, which sets down particular kinds of white-swellings as scrofulous, is founded on the hereditary nature of such forms of disease.

Numerous continental surgeons, particularly Petit and Brambilla, have noticed how very subject the English are both to scrofula and white-swellings of the joints. We every day see, that young persons afflicted with the present disease, are generally manifestly scrofulous, or have once been so. Very often enlarged lymphatic glands in the neck denote this fatal peculiarity of constitution; very often the patients are known to have descended from parents who had strumous disorders. Crowther.

Besides the general emblems of a scrofulous constitution, we may often observe a shining, coagulated staky substance, like white of egg, blended with the contents of such abscesses as occur in the progress of the disease. This kind of matter is almost peculiar to scrofulous abscesses, and forms another argument in support of the foregoing observations relative to the share which scrofula frequently has in the origin and course of many white-swellings. Cooper's Dict. of Practical Surgery.

The causes of white-swellings are divided by surgical writers into external and internal. Amongst the former are reckoned mechanical injuries of the joints, such as wounds, contusions, sprains, immoderate exercise in cold damp weather, residing continually in a low humid situation, &c. It is certain, however, that these tumours are seldom produced altogether by external causes; and even when their formation has been preceded by some external violence, this is rather to be regarded only as the determining cause of the disease, while the real cause in this, as well as in other cases where the complaint begins spontaneously, is of an internal kind. Rheumatism and scrofula are the ordinary causes of white-swellings; and it may be alleged, without risk of error, that more than three-fourths of these tumours are owing to these constitutional diseases. Those white-swellings which attack strong plethoric subjects of adult age, commonly depend upon rheumatism; while other cases which happen in children, are almost always caused by scrofula. It is well known that rheumatism is particularly disposed to make its attack upon the large joints, and that it especially affects the ligaments and neighbouring cellular substance, which it thickens and hardens, by causing an effusion of coagulable lymph. Hence, says Boyer, in

such white-swellings as arise from rheumatism, these parts alone are found diseased in the early stage of the complaint. *Traité des Mal. Chir.* t. iv. p. 501.

With respect to scrofula, every surgeon is aware that it frequently attacks the heads of the bones, particularly in children, occasioning those morbid changes which we have already endeavoured to describe. We have likewise mentioned what is now generally admitted, that in white-swellings originating from scrofula, the disease commences in the bones, the soft parts becoming affected only secondarily. The contrary is said to happen in all rheumatic cases, the disease beginning in the soft parts, and only affecting the bones in a subsequent advanced stage of the complaint.

The prognosis in cases of white-swelling is, generally speaking, unfavourable; but it is more or less so, according to the cause of the disease, its duration, the accompanying symptoms, the patient's constitution, &c. White-swellings arising from rheumatism are the least alarming, especially when they are recent. The progress of the complaint may then be often stopped, and sometimes a perfect cure accomplished. In this kind of case, the joint sometimes returns to its natural state, and regains the power of freely performing every motion; while in other instances, it continues affected with a greater or lesser degree of stiffness. White-swellings, which appear to depend altogether upon an external cause, in persons in other respects healthy and sound, may terminate well. The worst white-swellings of all are those which originate from scrofula; for they are very seldom cured, and when they do admit of amendment, the joint is always left in a state of ankylosis.

Whatever may be the cause of white-swellings, when they are of long standing, severely painful, the bones softened and rendered carious, the cartilages ulcerated, the articulation filled with sanious matter, and abscesses have formed, the openings of which continue fistulous, and emit a more or less abundant quantity of a thin fetid discharge, the disease is in general incurable. In this case, the violence of the pain, the hectic fever, the profuse sweats, and colliquative diarrhoea, plunge the patient into a state of marasmus, and soon carry him off, unless an attempt be made to save him by the timely performance of amputation. Yet, as Boyer observes, in some few cases of this hopeless description, nature, skilfully assisted by art, has been known to subdue the disease. The suppuration then gradually diminishes and assumes a better quality, the slow fever, nocturnal perspirations, and weakening diarrhoea, entirely cease, the appetite returns, digestion is well performed, the strength is restored, and the patient gets well with an ankylosis. But such fortunate cases are extremely uncommon, and they do not justify us in leaving the disease to nature, instead of amputating the limb. *Traité des Mal. Chir.* t. iv. p. 505. 507.

Of all the diseases which fall under the care of the surgeon, there is not one in which a greater variety of remedies has been proposed than in white-swellings. Yet, notwithstanding the numerous means which are occasionally tried, the practitioner frequently has the mortification of finding, not only that he cannot accomplish a radical cure, but that he cannot even palliate the complaint, moderate its violence, or retard its progress.

The surgeon, in order to be methodical, should adapt the treatment to the particular form of the disease and its different states. But, in every instance, perfect rest of the limb is absolutely indispensable, as exercise always has the effect of keeping up pain and irritation, and doing harm, whatever may be the species of the disease.

WHITE-SWELLING.

Rheumatic white-swelling being invariably accompanied, at their commencement, with an inflammatory character, there can be no doubt, that, at this period of the complaint, the great indication is to take such measures as are best calculated to lessen and subdue inflammation; and bleeding is what should first be practised. When the patient is strong, robust, and much fever exists, he may be bled once or twice in the arm; but, in other cases, we are to be content with drawing blood from the part affected with leeches, or by cupping. If leeches be used, they should be applied to both sides of the joint, and eight or ten ounces of blood ought to be thus taken away. The application of these animals should also be repeated at proper intervals, more or less frequently, according to the violence of the symptoms, and the strength of the patient. In cases of this description, drawing blood from the diseased part itself is found to be much more efficacious than general blood-letting, which weakens the patient without proportionately lessening the swelling of the joint.

Blisters are another means, as efficacious as topical bleeding. Boyer recommends beginning with the application of a small one to the front of the joint, where the leeches have not been put; and he says, that it should be kept open, until the bites of the leeches are healed on one side of the articulation, where a second blister is then to be applied. As soon as this is nearly healed, we are next advised to lay a third blister on the opposite side of the joint. By thus continually changing the situation of the blister from one side of the articulation to another, a permanent counter-irritation is kept up, which, says Boyer, in all deeply-seated inflammations, especially those which proceed from rheumatism, is much more effectual, than carefully maintaining a discharge from a single blister.

In conjunction with the foregoing means, the limb should be kept moderately and uniformly warm by covering it with flannel; a low diet is to be observed, cooling beverages prescribed, and the action of the bowels regulated by clysters. Thus, the severity of the pain may generally be lessened, and the inflammation diminished. If the pain, however, should still continue to be violent, Boyer recommends the use of topical anodyne and narcotic applications. He states, that, in this circumstance, he has often employed with success opiate and camphorated liniments; fomentations composed of a solution of the extract of opium in water; a strong decoction of poppies, &c. He thinks, however, that such applications should never be used, unless the pain be very severe.

When the inflammatory stage is over, topical resolvent remedies are to be employed, and their effect is to be promoted by exhibiting mild opening medicines at suitable intervals. The most effectual resolvent applications, and those which are most commonly tried in these cases, are, dry frictions with a piece of flannel, impregnated with the vapour of benzoin, liniments containing ammonia and camphor, ammoniacal plasters, soap-liniment, lotions of vinegar, spirit of wine, and the muriate of ammonia, &c. Mr. B. Bell had a very high opinion of the good effects of rubbing the joint with camphorated mercurial ointment; but Boyer affirms, that he has often tried the last application, and that his experience leads him to impute whatever benefit arises from its employment, chiefly to the frictions, which redden and promote the circulation in the skin.

By a perseverance in the judicious use of the means above specified, rheumatic white-swelling may sometimes be cured; but it often happens, that, after the pain and swelling have subsided, the joint remains quite stiff and

motionless, and every attempt to move it causes considerable suffering. In the majority of cases, such stiffness depends almost entirely upon the retraction of the muscles, tendons, and ligaments, and demands the same treatment as a false ankylosis. See ANCHYLOSIS.

When the disease resists the foregoing treatment, and is of long standing, the cure is more difficult, inasmuch as the thickening of the ligaments, and the effusion of a sero-albuminous fluid into the cellular substance around them, are more considerable, and the bones and cartilages are likewise at the same time affected. In this circumstance, if there be any hope of cure, the surgeon must have recourse to more powerful means, which we shall mention in speaking of the treatment of other descriptions of white-swelling.

In white-swelling, arising from an external cause, such as blows, falls, &c. we must first lessen the inflammation by general and local bleeding, low diet, cooling aperient beverages, fomentations, and emollient anodyne poultices. Afterwards, when the pain and tension have subsided, resolvent applications are to be used, and the patient is not to be allowed to move the limb, as long as there is any danger of a renewal of the pain and irritation by exercise.

Scrofulous white-swelling in an early stage present different indications, according to the circumstances with which they are accompanied. A fall, or blow upon a joint, being sometimes the exciting cause of these tumours, any accident of this kind in a person evidently disposed to scrofula demands the utmost attention and care. No means should be neglected which are at all likely to lessen the pain and irritation in the affected joint, and in particular the limb ought to be kept perfectly quiet for a long time. Scrofulous white-swelling frequently come on, as it were, spontaneously, without the concurrence of any external accident, and their attack is attended with a dull, sometimes an acute pain in the very cavity of the joint, which at first is not affected with any manifest degree of swelling. In this circumstance, the surgeon must endeavour to prevent the progress of the disease by enjoining the patient to refrain from moving the joint, and by directing the employment of soothing local applications, which are afterwards to be succeeded by blisters, or an issue.

In the cases of white-swelling, which appear from Mr. Brodie's account to depend principally upon inflammation of the synovial membrane, the acute stage of the disease is to be treated by general and local bleeding, aperient medicines, cold topical applications, or fomentations, and emollient poultices. When the affection has become chronic, this gentleman recommends perfect rest, and leeches, or cupping, followed by the application of a large blister. Under this treatment, he says, "the pain is relieved, and, in a few days, the swelling, as far as it depends upon the fluid collected in the cavity of the joint, is much diminished. Even where the tumour is solid, arising from the effusion of coagulating lymph, it will in a great measure subside, and sometimes be entirely dispersed, provided the lymph has not yet become organized. A single blister often produces marked good effects; but, it is generally necessary to repeat both the blister and the blood-letting several times." Mr. Brodie considers the repeated application of blisters more efficacious, than a single blister kept open with the avine cerate. When the inflammation has been much subdued, he thinks moderate exercise of the joint rather beneficial, and commends the use of a stimulating liniment, composed of $\frac{3}{4}$ ss of olive oil, and $\frac{3}{4}$ ss of sulphuric acid. This application, when too irritating, is to be weakened by an additional quantity of oil, and it is not to be used before inflammation

inflammation is subdued, lest it aggravate the disease. Issues and setons, which are useful in ulceration of the cartilages, Mr. Brodie deems useless in the present disease. Plasters of gum ammoniac, and others of a similar nature, are of little efficacy while inflammation exists, but afterwards they are of use in guarding the joint from the influence of external cold, and preventing a relapse. For the removal of a moderate degree of swelling and stiffness, left by the past inflammation, Mr. Brodie entertains a favourable opinion of exercise of the limb, and friction with camphorated mercurial ointment, or by the hand with finely powdered starch. When the friction, however, produces inflammation again, it is to be discontinued, and leeches applied. When the swelling and stiffness are considerable, Mr. Brodie has never seen friction do much good, and, as it is in such cases particularly apt to bring on inflammation again, it is to be employed with much caution. According to the same author, friction is more efficacious, where the stiffness of a joint depends on a contracted state of the muscles, or tendons of the limb, or on these being glued to each other, or the surrounding parts, than where it is the consequence of disease of the joint itself. In some cases, the pumping of warm water on the part, from a height of several feet, as practised at some of the watering places, is beneficial; but in this plan, the same cautions are necessary, as in the employment of friction.

With regard to the cases which Mr. Brodie describes as depending upon a total loss of the natural structure of the synovial membrane, which is converted into a pulpy substance, one-quarter, or one-half, of an inch in thickness, are, according to this gentleman, quite incurable, and they at length terminate in ulceration of the cartilages, abscesses, &c. Hence, when the health begins to suffer, he considers amputation proper. See *Medico-Chir. Trans.* vol. v.

When white-swellings are accompanied with ulceration of the cartilages, all motion of the joint is extremely hurtful. Indeed, as Mr. Brodie well observes, keeping the limb in a state of perfect quietude is a very important, if not the most important circumstance to be attended to in the treatment. According to the same writer, it is in these cases, in which ulceration of the cartilage occurs as a primary disease, that caustic issues are usually productive of singular benefit; but he deems them of little use in any other diseases of the joints. He thinks setons, and blisters kept open with the favine cerate, may also be used with advantage in the same description of cases. Bleeding can only be proper, when, from the bad effects of exercise, the articular surfaces are inflamed, and pain and fever prevail. Mr. Brodie assures us, that the warm-bath relieves the symptoms in the early stage, if it does not stop the progress of the disease; but he condemns plasters of gum ammoniac, embrocations, liniments, and frictions, as either useless or hurtful. *Op. Cit.* vol. vi.

The pumping of warm water upon diseased joints is a method which is at present very frequently adopted, as more conceive, with decidedly beneficial effects. The plan is not altogether modern. Le Dran, and several other old practitioners, recommend throwing warm water upon diseased joints, and they prove the advantages of this treatment by a relation of many successful cases. In order to derive the greatest possible good from the plan, the water should be as warm as the patient can bear it, and it ought to fall upon the part from a height of seven or eight feet. The size of the stream must also vary according to the degree of sensibility in the tumour. When the pain is acute, the end of the pipe must be closed with a piece of tin, perforated by many holes, like the spout of a watering-pot. But when

the pain is inconsiderable, the pipe may terminate in a single opening, the diameter of which should vary from half an inch to an inch, according to circumstances. The application is sometimes to be continued nearly an hour, and when it is finished, the patient ought to go to bed, and the joint be covered with bladders filled with water as hot as the patient can bear. Boyer recommends the application of the bladders to be persevered in for the space of two hours, after which they are to be removed, and perspiration from the part promoted by covering it with warm cloths, or flannels. In the evening, the bladders are to be repeated for some hours. The dashing of warm water against the diseased joint is to be practised every day, or every other day, according as the patient can bear the plan, without too much fatigue or inconvenience. This treatment, says baron Boyer, is proper in all kinds of white-swellings, and in every stage of the disease; but it is much the most useful in those cases in which the soft parts alone are affected, and at an early period, before the complaint has made great progress. Favourable effects may be expected from this method, when, after each application of the water, the part affected perspires copiously, when it grows gradually softer, and when, after a certain number of trials, the swelling begins to diminish. Under these circumstances, the plan is to be continued and repeated very often, as a long perseverance in it has frequently produced extraordinary cures. When none of the above-described changes happen, little benefit can be hoped for from the method; but still the patient should not abandon it, before its inefficacy has been proved by adequate trials.

When there is no suitable apparatus for applying the warm water, it may be injected against the part with a large syringe, which has a pipe about half an inch in diameter made with four or five holes, for the discharge of the fluid. The injections may be rendered more or less active, by compelling the water with more or less force.

These affusions operate only by the heat and strength of the current of water. Boyer states, that their activity may be augmented by adding to the fluid a quantity of the muriate of soda or muriate of ammonia, or some potassa or soda; and he thinks it still better to employ a sulphuretted mineral water, either natural or factitious. The activity of the affusions may also be increased by heating the water to a high temperature, letting it fall from a considerable height, and making the stream large. It is a plan, says baron Boyer, adapted to those white-swellings which are situated in the soft parts on the outside of the joints; and which are indolent, and unattended with much pain. When these active affusions are applied to white-swellings which are painful, and which affect the bones, they often increase the patient's sufferings, and accelerate the progress of the disease. See *Traité des Mal. Chir.* tom. iv. p. 512, &c.

Of late years, surgeons have frequently made trial of dry-rubbing, as it is termed, or friction of the joint, performed with the hand, for several hours a day, with the mere application of a little powdered starch, or hair-powder, in order to prevent the part from being chafed. It is a method which was first practised to a considerable extent at Oxford, and with great success. Many poor women there earned a livelihood by rubbing diseased joints at the rate of sixpence *per* hour. Indeed, there can be no doubt, that, in indolent rheumatic white-swellings, simple friction often removes the swelling in an expeditious manner, as well as the stiffness of the affected joint. The plan, however, will not effect a cure in scrofulous cases; nor can it be adopted without manifest

harm in any examples, in which the disease is either in an inflamed or irritable state.

In chronic cases, the swelling may also be lessened, and the complaint sometimes much benefited by pressure, made either with strips of adhesive plaster, or with bandages. This method will not do much good in instances where the bones are diseased, nor is it applicable to cases which are irritable, or attended with heat and inflammation.

For scrofulous white-swelling, surgery cannot yet be said to have discovered any effectual or certain means of relief; and these melancholy diseases frequently compel the patient to submit to amputation, as the only thing by which a long train of sufferings can be arrested, and the term of life extended. The common plan of treating scrofulous white-swelling is, by topical bleeding, fomentations, and cold applications, when they are attended with much pain, heat, and irritation; and by issues, setons, and blisters, in other periods of the disease. The cautery and moxa have also been much employed abroad; and, as every body knows, they were favourite and powerful remedies in the hands of the ancients. In this country, the use of actual fire in surgery is nearly, if not quite, exploded, on the ground that its employment is attended with an appearance of cruelty, and that issues, made with caustic, are equally efficacious. Pouteau, an eminent French surgeon, will ever be famous for having revived in his own country all the ancient partiality to burning irons. He recommended their use for all white-swellings without discrimination; and the accounts which he has left of the success of the practice are surprising, if not incredible. In fact, they are in all probability great exaggerations; for we find that baron Boyer, one of the most eminent surgeons at Paris at the present time, decidedly declares his opinion, that Pouteau's descriptions of the efficacy of the actual cautery in the cure of white-swellings do not correspond with the results of modern experience. Boyer himself gives a preference to the moxa, which is a cone of cotton, burnt upon the diseased part, so as to produce an eschar. We confess, that to us this plan seems to have no material difference from the cautery; and, what is it but the application of actual fire in another form? Indeed, one cannot help thinking, that Boyer decries the cautery, only for the purpose of afterwards recommending the moxa, which is now a more fashionable means employed in French surgery. It is curious to find Boyer particularly forbidding the use of issues, and the moxa in cases of white-swelling, where the bones and cartilages are diseased; the very cases in which Mr. Brodie, in common with the generality of surgeons in England, expressly recommends either issues or perpetual blisters. Boyer has never seen much good arise from issues in any cases, although, as he affirms, he has made extensive trial of them. The time also when he thinks the moxa useful, is in that stage of the complaint which intervenes between the prevalence of inflammatory symptoms, and the commencement of disease in the bones and cartilages. Sometimes, however, the disorder certainly has its very origin in the bones themselves.

The late Mr. Crowther introduced the plan of keeping open blisters with the favine cerate, which is a method frequently attended with great success in chronic white-swellings, and sometimes appears to check the progress of the scrofulous form of the disease. Blisters may be kept open with this ointment a long time, and with less pain, than what proceeds from the use of the unguentum lyttæ, and other stimulating dressings. It also occasions no risk of bringing on strangury, or inflammation of the bladder and urinary organs, like the use of ointments containing can-

tharides. In our opinion, Mr. Crowther had much merit in making known the eligible qualities of the favine cerate; and, we believe, no better application for keeping up a discharge from blisters will ever be found out. Sometimes, however, the repeated application of blisters has more effect upon white-swellings, than a single blister kept open. This is a circumstance which the practical surgeon ought constantly to remember.

We might enlarge this article with observations on issues and setons, which are frequently employed in these cases; but it would be superfluous, as they have been already described in other parts of the work. See *ISSUE*, and *SETON*.

It may be supposed, that scrofulous white-swellings will require the exhibition of the remedies usually administered in cases of scrofula. (See *SCROFULA*.) Boyer, and some other writers declare, that this is actually the case. We have never seen these remedies, however, do any good to diseased joints, if we except sea-air, sea-bathing, and the use of sea-water lotions and poultices, which sometimes prove useful.

After all, we must acknowledge that white-swellings, we mean particularly the instances accompanied with ulceration of the cartilages, and disease of the heads of the bones, are cases which too generally baffle the utmost skill, and render a formidable operation unavoidable.

WHITE Tail. See *MOTACILLA Ceanothe*.

WHITE Tartar. See *TARTAR*.

WHITE Thorn. See *CRATÆGUS*.

WHITE Thorn, or Hawthorn. See *HEDGE*, and *QUICK-SET-Hedge*.

WHITE Thorn Layer, a term applied to such plants of the white thorn kind as are laid down in hedges to grow, in the operation of plashing. Also to the young roots of this thorn used in raising this sort of hedges. See *PLASHING Hedges*.

WHITE-Throat, in *Ornithology*, the name of a small bird, very common in our gardens and hedges, and seeming to have been described under the name of *spipola* by Aldrovandus and some others, though most approaching to the *ficedula* class.

Its beak is black above, and whitish below; its feet of a yellowish-brown; its neck and back are of a brownish-grey; its head more grey than either, and the upper part of the throat white, the rest reddish; its breast and belly are also a little reddish; but in the female, the breast is perfectly white. The edges of the long wing-feathers are some whitish and others brownish, and the tail is variegated with black and white, and some grey or ash-colour intermixed. It is extremely common in our gardens and orchards in summer, and feeds on flies, spiders, and other insects, but leaves us in winter. It builds in bushes, at a small height from the ground, with stubble and horse-hair, and lays five brownish-green eggs, with black spots. Its note is continually repeated, and often attended with odd motions of the wings: it is harsh and displeasing. This bird is shy and wild, and seems of a pugnacious disposition. Ray and Pennant. See *MOTACILLA Sylvia*.

WHITE Trefoil, in *Agriculture*, is said, in the third volume of the *Essays of the Highland Society of Scotland*, to be a humble but sweet plant, which delights in a dry sound field, properly cleaned and limed; and is alone the delight of sheep. But that a mixture of it, and of the seeds of rye and rib grass, constitutes one of the best sheep-pastures that can be formed by the industry of man. That this sort of grass is likewise perennial, and that it enriches instead of impoverishing the soil or land. This has generally been

noticed to be the most abundant plant in such rich improved pastures; but that it has seldom been seen in lands remarkable for inducing the rot among sheep. See ROT, SHEEP, and WHITE Clover.

WHITE, *Troy*. See TROY-White.

WHITE *Varnish*, and *Vitriol*. See the substantives.

WHITE *Vitriol*, in *Mineralogy*, a natural salt or ore of zinc. (See ZINC, and ZINC Ores.) This ore is a sulphate of that metal, but is frequently combined with a small portion of manganese. It is supposed to be formed naturally by the decomposition of blende or sulphuret of zinc.

WHITE-*Washing*, *Roughcast*. See WASH for, &c.

WHITE *Water*, a disease in *Sheep*, of the dangerous stomachic kind. It is said to be caused by their feeding on rich succulent food in cold frosty seasons, or at other times, and by many other such causes; and is probably an affection of the inflammatory kind.

It is remarked in the Gloucester Report on Agriculture, that the white water is a destructive disorder on the Cotswolds; usually comes on with rapidity, and sometimes terminates with death in three hours. It is supposed to be owing to their licking up the white frost on their green food in spring and autumn. Folding at night on bare ground, giving them dry meat in the morning, and keeping them from the turnips till the frost is gone, is the obvious mode of prevention, if the foregoing cause be well founded. If, however, the disorder be owing to gorging themselves with watery food, such as turnips, it is probable that to keep them moving, without suffering them to rest long, nor swell with what they have eaten, will carry off the beginning complaint; and even if the white frost has been the occasion, this is the best remedy that reasoning suggests; and it is said to be the practice of the shepherds in Northumberland, in the management of sheep under this complaint.

It is probable that speedy evacuation, both by bleeding and purging, may be found useful in this disease, and afterwards the use of stomachic remedies.

It is found to chiefly attack the young healthy sheep. See WATER, *Red and Black*.

WHITE *Water-Lily*, in *Gardening*, a most beautiful plant of this country, which is capable of being propagated in artificial and ornamental pieces of water in gardens and pleasure-grounds, merely by transplanting the bulbous roots of it in the winter season. It is perennial in its nature.

WHITE *Wax* is yellow wax blanched, and purified by the sun and dew. See WAX.

WHITE *upon White*, in the *Porcelain Manufactory*, a name given by the English merchants to a particular china-ware, which is formed of three different white substances, the body being of one, the flowers of another, and the varnish which covers these of a third. See HOACHE.

WHITE *Wine* is that of a clear, bright, transparent colour, bordering on white. It is thus called to distinguish it from the red wines, or clarets.

The generality of white wines are made from white grapes; though there are some from black ones, only the skins are carefully kept from tinging them. See WINE.

WHITES, the popular name of a disorder incident to women. See FLUOR *Albus*.

WHITE, in *Geography*, a county of West Tennessee, with 4028 inhabitants, including 283 slaves.

WHITE *Bay*, a bay on the east coast of Newfoundland. N. lat. 50° 10'. W. long. 56° 25'.—Also, a bay on the east coast of Kerguelen's Land, south of Point Pringle, so called from some white spots of land or rocks. In the

bottom are several smaller bays or coves. S. lat. 47° 53'. E. long. 69° 15'.

WHITE *Bear Lake*, a lake of North America, said to be the most northerly of those lakes which supply the Mississippi. It is about 60 miles in circumference. N. lat. 46° 50'. W. long. 95° 30'.

WHITE *Cliff*, or *Culver Cliff*, a cape of the east coast of the Isle of Wight. North of it is a bay called White Cliff Bay. N. lat. 50° 39'. W. long. 0° 56'.

WHITE *Deer*, a township of Pennsylvania, in North Cumberland county, on the Susquehanna, with 1132 inhabitants.

WHITE *Flag Bay*, a bay on the west coast of the island of St. Christopher; 2 miles N. of Sandy Point.

WHITE *Head*, a cape of Ireland, on the coast of Antrim, at the entrance into Belfast Lough, a little to the south of Black Head.

WHITE *Hills*, a fishing-town of Scotland, in the county of Bamff, situated in a creek; 2 miles N. of Bamff.

WHITE-*Horse Vale*, a vale of Berkshire, so called from the figure of a horse in a galloping posture, cut in the side of a chalky hill, as is supposed in memory of a great victory gained by Alfred over the Danes in the year 871. The scouring the horse is an annual festival, and celebrated by rural games. On the top of the hill is a large Roman intrenchment, called Uffington castle, or Woolston castle. There is likewise another camp in the neighbourhood, with the burial place of the Danish chief, inclosed by stones set on edge, a cromlech, and several barrows.

WHITE *Horses*, cliffs on the south coast of Jamaica; 20 miles E.S.E. of Kingston.

WHITE-*House Bay*, a bay on the west coast of the island of St. Christopher, a little to the north of Guana Point.

WHITE *Inlet*, or *Boca de Ratones*, an inlet on the east coast of East Florida. N. lat. 26°. W. long. 80° 20'.

WHITE *Island*, an island in the South Pacific ocean, near the east coast of New Zealand, north of Cape Run-away. S. lat. 37° 31'. W. long. 182° 36'.—Also, a small island in the Atlantic, near the S.E. coast of Nova Scotia. N. lat. 44° 55'. W. long. 61° 56'.

WHITE *Island*, or *Burnt Island*, a small island in the Arabian Gulf, near the coast of Adel. N. lat. 11° 8'. E. long. 64° 55'.

WHITE, *Isle of*. See *Isle of WIGHT*.

WHITE *Keys River*, a river of Africa, which runs into the Indian sea, S. lat. 30° 35'.

WHITE *Mountains*, mountains of New Hampshire, peculiarly applied to the highest part of a ridge, which extends N.E. and S.W.: the whole circumference at least fifty miles. The height of these mountains above an adjacent meadow is reckoned, from observations made by the Rev. Mr. Cutler, of Ipswich, in 1784, to be about 5500 feet, and the meadow 3500 feet above the level of the sea. The snow and ice cover them nine or ten months in the year, during which time they exhibit that bright appearance from which they are denominated the White Mountains. From this summit, in clear weather, is exhibited a view extending sixty or seventy miles in every direction: although they are more than seventy miles within land, they are seen many leagues off at sea, and appear like an exceedingly bright cloud in the horizon. These immense heights, being copiously replenished with water, afford a variety of cascades. Three of the largest rivers in New England receive a great part of their waters from these mountains. Amanoosuck and Israel rivers, two principal branches of the Connecticut, fall from their western sides. Peabody river, a branch of the Amoriscongen, falls from the north-east side, and almost

the whole of the Saco descends from the southern side. The highest summit of these mountains is in about 44° N. lat.

WHITE Oak Creek, a river of North Carolina, which runs into the Atlantic, N. lat. $34^{\circ} 39'$. W. long. $77^{\circ} 26'$.

WHITE Oak Mountains, mountains in the west part of North Carolina. N. lat. $36^{\circ} 10'$. W. long. $82^{\circ} 30'$.

WHITE Point, a cape on the coast of Cape Breton, near Louisburg.—Also, a cape on the south coast of Jamaica; 20 miles E. of Port Royal.—Also, a cape on the north coast of the island of Cumbava. S. lat. $8^{\circ} 15'$. E. long. $118^{\circ} 51'$.

WHITE River, a river of Louisiana, formerly thought to be a stream of inconsiderable magnitude, but now known to be one of the most considerable in the western country, and likely to become of still greater importance. It rises in the Black Mountains, which separate the waters of the Arkansas from those of the Missouri and Mississippi. Several of its branches interlock with those of the Osage river, the Maramak, and the St. Francis. It is navigable about 1200 miles, without any considerable interruption; 800 of which may be made with barges, and the rest with canoes or smaller boats. Its waters are clear and limpid, its current gentle, and even in the driest season, plentifully supplied from the numerous and excellent springs which are every where found. It also receives many considerable rivers in its course, the largest of which is Black river. The country which it waters is described by those who have traversed it as generally well wooded, and abounding in springs and rivulets: the soil is rich, though hilly; and it is said, that on the borders of this river a country may be chosen, at least 100 miles square, not surpassed by the best parts of Kentucky, and one of the best for settlements in the western world. This river is situated on the S.W. side of the Missouri, and is 300 miles wide at its mouth.

WHITE River, a river of Guadeloupe.—Also, a river of America, which runs into the Connecticut, 4 miles east of Norwich.—Also, a river of Jamaica, which runs into the sea, 4 miles W. of Morant bay.—Also, a river of Indiana, in the county of Koog, which rises about N. lat. $40^{\circ} 45'$, and W. long. $85^{\circ} 5'$, and runs into the Wabash, N. lat. $38^{\circ} 19'$, and W. long. $88^{\circ} 20'$.—Also, a river of America, which runs into lake Michigan, N. lat. $43^{\circ} 40'$. W. long. $85^{\circ} 35'$.—Also, a river of Vermont, which runs into the Connecticut, N. lat. $43^{\circ} 38'$. W. long. $72^{\circ} 16'$.

WHITE Rock, a rocky islet in the East Indian sea, near the south coast of Java.

WHITE Rocks, a range of buildings, accommodated for smelting-houses, about a mile from Swansea, in the county of Glamorgan, situated on the river.

WHITE'S Bay, a bay on the coast of Newfoundland. N. lat. $50^{\circ} 17'$. W. long. $56^{\circ} 15'$.

WHITEBURN, a town of Scotland, in the county of Linlithgow; 21 miles W. of Edinburgh.

WHITECLAY CREEK, a hundred of Delaware, in Newcastle county, with 1701 inhabitants.

WHITEFIELD, GEORGE, in *Biography*, one of the founders of Methodism, (see *METHODISTS*,) was the son of an innkeeper at Gloucester, where he was born in 1714, and where he received the rudiments of literature, so as to be sufficiently qualified for his father's business, for which he was designed. Accordingly he commenced it as drawer at the Bell-inn. At school he is said to have been distinguished by a retentive memory and good elocution. Of his early years, he gives a very unfavourable account, so that there was nothing about him but a fitness to be damned, with occasional gleams of grace that afforded some indication of his future destination. About the age of 18,

he was admitted a servitor at Pembroke college, Oxford, and associated with those young persons whose dispositions and habits resembled his own, and whose conversation and manners contributed to cherish that religious enthusiasm to which he was strongly addicted. As soon as Dr. Benson, bishop of Gloucester, received information concerning the state of his mind and the course of his general conduct, he made him an offer of ordination, when he was about 21 years of age, and he was accordingly ordained a deacon in 1736. Upon his return to Oxford, after preaching his first sermon at Gloucester, he took the degree of bachelor, and diligently employed himself in communicating instruction to the poor and the prisoners. During the two following years, he acquired a great degree of popularity by his public services in London, Bath, Bristol, and other places; collecting large auditories, and interesting the attention of his hearers. His voice was strong and musical, his pronunciation clear and distinct, his imagination was lively, and his feelings were warm; and to these natural powers of eloquence we may add his selection of subjects, which were adapted to rouse the inconsiderate, and to comfort those that were awakened to a sense of their guilt and danger: so that we need not wonder that he should command a numerous audience. Upon receiving information that the province of Georgia was likely to open to him an extensive field of usefulness, he determined to visit it, and in May 1738, arrived at Savannah. Here he met with much greater success than his predecessor Wesley; and in order to supply the defect of education which he was concerned to observe in this province, he resolved to found an orphan-house, and in 1739 returned to England in order to collect money for this purpose. In England few of his clerical brethren were disposed to take much notice of him; nevertheless, his original patron, the bishop of Gloucester, gave him priest's orders: but upon afterwards visiting London, none of the churches into which he obtained admission were large enough to accommodate the crowds of people that assembled to hear him. It was about this time that he commenced his practice of preaching in the open fields, and the first scene of his exhibition in this way seems to have been Kingwood, near Bristol, where he collected thousands, chiefly of colliers, who without doubt derived benefit from his discourses. He also preached at Bristol in the open air, when he was refused access to the pulpits of the churches; and he likewise pursued the same practice in Moorfields and Kennington-common, near London, where, amidst the immense multitude that attended him, some persons occasionally treated him with rudeness, but the greater number were commanded by his peculiar power of address into respectful attention. Having succeeded beyond his expectations in soliciting contributions for his projected orphan-house in Georgia, he returned to America in August 1739; and in the following January laid the foundation of the building at Savannah. He then extended his tour as far as Boston, preaching to immense crowds, and collecting considerable sums for the completion of his design; and upon his return to Savannah he found his orphan family comfortably settled in their house; and in January 1741, he embarked for England. His absence had occasioned a declension among his followers; some other circumstances, besides the intermission of his personal labours amongst them, might probably have contributed to produce this effect. Whilst he was in America he had written, as he himself acknowledges, "two well-meant but injudicious letters against England's two great favourites, the Whole Duty of Man, and archbishop Tillotson, who, I said, knew no more of religion than Mahomet." His society had suffered from the influence of the Moravians. Mr. Wesley

had preached and printed in favour of perfection and universal redemption, and against the doctrine of election. He had written a reply, but he acknowledges that he had used expressions that were too strong in reference to absolute reprobation, which had offended numbers of his spiritual children. His worldly circumstances were embarrassed, and he owed 1000*l.* for the orphan-house, and some of his bills were returned. He had some enemies who circulated reflections on his integrity in the contract of this business; but they were never justified, and his state of secular affairs at his death affords a strong presumption that they were groundless. Dr. Franklin, who lived upon the spot, bears testimony to his honesty. At this time, a separation had taken place between him and Wesley, and this had occasioned a decrease of his auditors. However, his zeal and perseverance overcame these difficulties. In order to counteract Wesley's popularity, he built a shed near his chapel in Moorfields, which he called the Tabernacle; and in process of time this rose from a mean beginning to be a spacious edifice; and he also renewed his field-preaching. At this time, he paid his first visit to Scotland; and though he was a clergyman of the church of England, which excited some prejudice against him, he was invited into the churches, and preached to large congregations, and made collections for his orphans. On his return by Wales, he married a Mrs. James, a widow lady of Abergavenny. His zeal for doing good, and for making profelytes, induced him, in the spring of 1742, to engage in a contest with the idle people who had booths in Moorfields, and where they frequented for their amusement on holidays. On Whitmonday he collected a party of his attendants, and resorted to the spot with a view of conducting a religious service. Although he was much disturbed in this effusion of his piety and zeal, the result, as he says, was so much in his favour, that he received 1000 notes from persons under conviction; and soon after more than 300 were admitted into the society in one day. In 1748 he returned from a third voyage to America; and then commenced his acquaintance with the countess of Huntingdon, who appointed him her chaplain, and excited the curiosity of some persons of rank to hear him: among these were the earl of Chesterfield and lord Bolingbroke. About this period, it is said, his sentiments became more rational; for on his third visit to Scotland, it was announced to a synod assembled at Glasgow to investigate certain charges against his opinions, that with regard to certain points which were considered as objectionable, his sentiments had been altered for upwards of two years; and that he now seldom preached a sermon without guarding his hearers against impressions, and admonishing them that a holy life is the best evidence of a state of grace. From this time, he was fully employed by a visit to Ireland, two more voyages to America, and his English circuits, till the year 1756, when his chapel in Tottenham-court-road was erected. His labours were incessant for many years; but at length, on a seventh visit to America, he was seized with an athmatic complaint at Newburyport, New England, which terminated his life in September 1770, near the completion of his fifty-sixth year.

With regard to his general character, we shall close this article with the reflections of a judicious and candid biographer. "That he had much enthusiasm and fanaticism in his composition is sufficiently evident from his own journal and letters; but whether these were accompanied, as they not unfrequently are, with craft and artifice, is a disputable point. There are, in his narratives, obvious marks of a disposition to represent himself as under the special protection of Providence, and to magnify trifling incidents into little less than miracles in his favour; and much of what is com-

monly called cant is apparent in his confessions and humiliations. Yet that he was a hypocrite acting a part will scarcely be believed by any one who looks at his course of life during 34 years. He has been charged with dishonesty and immorality; yet as it is certain that he obtained the esteem of many persons of worth, it may be concluded that such accusations were destitute of proof. His intellectual qualities were well suited to the task he undertook; and if in the pulpit he occasionally intermixed buffoonery with his vehemence, the latter was not less effectual on that account. His learning and literary talents were mean, and he is a writer only for his own sect." He published, at intervals, sermons, tracts, and letters, which, after his death, were collected in six vols. 8vo. *Middleton's Biog. Evangel. Mosh. Eccl. Hist. Gen. Biog.*

WHITEFIELD, in *Geography*, a town of America, in the district of Maine, and county of Lincoln, having 995 inhabitants.—Also, a town of New Hampshire, in the county of Cowes, having 51 inhabitants.—Also, a town of North Carolina; 40 miles W. of Newbern.

WHITEFIELD, or *Wheatfield*, a township of Pennsylvania; 156 miles W. of Philadelphia.

WHITEHALL, formerly called Skenesborough, a post-township of Washington county, in the state of New York, at the head of lake Champlain, about 65 miles N.E. from Albany: in medial length about 10 miles from N. to S., and 7 wide; first erected in 1788, with its present limits. The soil is a stiff clay, and adapted to grass. Wood-creek and Pawlet river unite in this town, and afford facility to navigation and trade, as well as mill-seats. Marble, limestone, and iron-ore, and also a mineral spring, are found in this township. It has 1 Congregational, 1 Presbyterian, 1 Baptist, and 1 Methodist congregation, and a competent number of common schools; 2 grist-mills, 2 saw-mills, a fulling-mill, and carding-machine.—Also, an incorporated post-village at the N. end, with considerable trade, situated principally on the W. bank of Wood-creek, at its entrance into lake Champlain; 71 miles N.E. from Albany. About a quarter of a mile from the village is a handsome Presbyterian church, founded by the donation of John Williams, esq. of Salem, who endowed it with a parsonage of 60 acres of land. The whole population, by the census of 1810, was 2119, with 178 electors.—Also, a township of Pennsylvania, in Northampton county, with 2551 inhabitants; 61 miles N. of Philadelphia.

WHITEHAVEN, a sea-port and market-town in Allerdale ward, in the county of Cumberland, England, is situated between two hills at the northern extremity of a narrow vale, at the distance of 40 miles S.W. from Carlisle, and 305 miles N.W. from London. The rise, progress, and increasing importance of this now rich and flourishing town, strikingly display the effects of trade, industry, and enterprise. From an obscure hamlet, it has advanced, within less than two centuries, to considerable magnitude and commercial importance; and, both in extent and population, by far exceeds the capital of the county. In the year 1566, it consisted only of six fishermen's cabins; in 1633, of nine or ten thatched cottages; but in 1693, its buildings were sufficiently numerous for 222 inhabitants, and have been progressively increasing; till, in the year 1811, the population was returned to parliament as 10,106, occupying 1940 houses. The increase of shipping has been proportionate: in 1685, the whole number of vessels belonging to this port was 46, carrying 1871 tons; they have since gradually increased to 230; the quantity of tonnage is nearly 74,000 tons. The honour of raising this town to its present importance must be attributed to the Lowther family.

family. Sir John Lowther, about the beginning of the reign of Charles I., purchased the lands of the dissolved monastery of St. Bees for his second son, sir Christopher, who, as coals about that period came into general use, conceived the idea of improving his possessions by opening some collieries. No effectual progress was, however, made till after the Restoration, when another sir John Lowther, who had succeeded to the estate, formed a plan for working the mines on a very extensive scale. To obviate all opposition to his operations, he procured a gift of all the ungranted lands within the district, and also of the whole sea-coast for two miles northward, between high and low water mark. He then directed his attention to the port, which was small and inconvenient; and, by his judicious schemes, laid the foundation of the present haven. Subsequent improvements have been made, particularly during the reign of George II., when an act was passed to perfect and keep it in repair, by a tonnage on shipping. The mines are said to be the deepest in England, and extend a considerable way under the sea: one has been carried 1000 yards out from the shore, at the depth of 112 fathoms under the water. Most of the coal exported from this haven is conveyed to Ireland; the quantity raised annually, on the average, is about 90,000 chaldrons. (See COAL.) The creek on which Whitehaven is built is so deeply seated, that the adjacent lands overlook it on every side. The approach from the north is singular, as the heights are so much above the town, that only the roofs of the houses can be seen till near the entrance, which, on this point, is through an archway of red free-stone. The town itself is one of the most respectable in all the northern counties; the streets being regular and spacious, and crossing each other at right angles; the houses in general are well built, and even the tradesmen's shops exhibit a degree of elegance. Here are three chapels, plain convenient structures: they were all erected by subscription of the inhabitants, aided by the benevolence of the Lowther family. St. Nicholas's chapel was built in 1693; Trinity, in 1715; St. James's, in 1752. The latter is neatly fitted up; the roof and galleries are supported by ranges of pillars. Besides the established chapels, here are three meeting-houses for Methodists, two for Presbyterians, and one for each of the following sects, Anabaptists, Roman Catholics, Glassites, and Sandemanians. The principal manufactures are those of cordage and sail-cloth; the latter was only established in 1786, but already gives employment to several hundred workmen, though much of the business is executed by machinery of great power. A fair is held annually, and there are three weekly markets. The castle, as it is called, adjoining the east side of the town, one of the seats of the earl of Lonsdale, is a large quadrangular building, chiefly erected by the late earl, and containing some good paintings.

St. Bees, in which parish Whitehaven is situated, derives its origin from a religious house founded here by Bega, an Irish saint, about the year 650. On her death, a church was erected to her honour; but both these establishments having been destroyed by the Danes, they were replaced, in the reign of Henry I., by a new foundation for Benedictine monks. The church built at this period had the form of a cross, and great part of it yet remains. The east end is unroofed, and in ruins; the nave is fitted up as the parish church; and the cross-aisle is used as a burial-place. The whole is of a red free-stone. In this village a free-school was founded by a bequest of archbishop Grindall, in the year 1587, under a charter of queen Elizabeth. The endowments were increased by James I., and have been since further augmented by various benefactions.—*Beauties of England and Wales*, vol. iii. Cumberland, by J. Britton

and E. W. Brayley, 1802. *Magna Britannia*, Cumberland, by Messrs. Lysons, 4to. 1816.

WHITEHEAD, WILLIAM, in *Biography*, an English poet, was born at Cambridge in 1714-5, educated at Winchester school, where from his talent in writing verse he acquired the notice of Pope; and upon his return to Cambridge, obtained a scholarship of Clare-hall. As a poet, Whitehead's highest ambition was to resemble the manner of Pope; and of his proficiency he gave a specimen in his "Epistle on the Danger of writing Verse," 1741. In the following year he was elected fellow of Clare-hall, and pursued his studies with a view to the church; but his poetical talents produced a change in his circumstances and in his purpose. Being recommended to the earl of Jersey as a proper tutor for his eldest son, he removed in 1745 to the earl's house in London, where his treatment was in the highest degree liberal. Having leisure for indulging his taste for literary pursuits, he turned his attention to dramatic composition, and produced a tragedy, entitled "The Roman Father," which was exhibited with applause upon the stage in Drury-lane in 1750. In 1754 he published another, the title of which was "Creusa," which was also favourably received. With the profits arising from these two performances he very honourably discharged the debts of his father, who had died insolvent. In this year he accompanied his pupil, viscount Villiers, and viscount Nuneham, son of earl Harcourt, on their travels, which continued more than two years; and on his return he published an "Ode to the Tiber," and six elegiac epistles, which were much applauded. Lady Jersey, during his absence, had procured for him the appointment of secretary and register to the order of the Bath; and in 1757, on the death of Cibber, he succeeded to the laureat, which he rendered respectable; though in the discharge of the customary duties of the office, he did not escape abuse, and especially that of Churchill, whose popular satire almost overwhelmed the reputation of the laureat. Lady Jersey, in consideration of his services as governor to her son, invited him to take up his residence in her house, where he passed fourteen years, frequently visiting lord Harcourt, much respected by his noble hosts and his former pupils. He still amused himself by presenting to the public occasional productions, one of which was a comedy of the moral or sentimental class, entitled "The School for Lovers." After passing through life tranquilly and pleasantly, and maintaining an estimable character, he died suddenly, April 1785, in his 70th year. Of his works two volumes were published by himself, and to these a third was added by Mr. Mason, who prefixed memoirs of his life and writings, to which we refer. *Gen. Biog.*

WHITEHEAD, GEORGE, an eminent person among the Quakers, was born in 1636 at Sunbigg, in Westmoreland. Attaching himself early in life to this society, and engaging in the propagation of its doctrine, he partook of the sufferings which, in that age, were the ordinary lot of its active members; and was once, simply for having preached at Nayland, in Suffolk, severely whipped by order of two justices as a vagabond; a proceeding which served, as might have been expected, to increase the disposition of the people to hear him. Soon after the Restoration of the monarchy, the Quakers were made the express subjects of a law, the precursor of others of like nature, which imposed on their profession and worship penalties extending to banishment. In the progress of the bill through the house of commons, Whitehead, with three other Quakers, was admitted to the bar of the house, and heard in defence of the society. They pleaded its cause with the freedom of conscious innocence,

cence, and the meekness of men prepared to suffer, but pleaded in vain:—the bill passed, and two out of the four, who had thus advocated the rights of conscience, presently fell victims to the force by which conscience was deliberately oppressed, dying in a crowded unhealthy prison, to which they were dragged from their peaceable religious meetings. Whitehead, who was imprisoned with them, survived to be liberated.

In the year 1672, when Charles II. issued his declaration for suspending the penal statutes against non-conformists, Whitehead solicited and obtained an order under the great seal for the discharge of about four hundred Quakers, many of whom had been for years under close confinement. He records, with expressions of satisfaction, the circumstance that some other dissenters also partook at this time of the benefit of his exertions. On several other occasions he was concerned in applications on the Quakers' behalf to Charles II. and James II. And after the Revolution, when the Toleration Bill was before parliament, he was particularly serviceable to his friends in that matter; as likewise in taking a part in those representations, which procured the acceptance of their affirmation in lieu of an oath. A profession of faith being proposed for insertion in the above act, in terms which to the Quakers would not have been quite satisfactory, Whitehead and his coadjutors proposed the following, as their own belief on the points to which it relates, and which was adopted as a test for the society accordingly, *viz.* "I profess faith in God the Father, and in Jesus Christ his Eternal Son the true God, and in the Holy Spirit, one God, blessed for evermore; and do acknowledge the holy scriptures of the Old and New Testament to be given by divine inspiration."

Whitehead lived the greater part of his time in or near London, which accounts for his being one of those Quakers usually concerned in applications to the government. He was well esteemed by his brethren, whom he continued to edify by his ministry and example to the end, dying, after a short confinement, by infirmity, at the age of 86. Besides several writings chiefly controversial, he left some memoirs of his life, which were printed in one volume, 8vo. in 1725.

WHITEHEAD, in *Geography*, an island in the Atlantic, near the coast of Maine. N. lat. $44^{\circ} 43'$. W. long. $67^{\circ} 40'$.—Also, a cape of Ireland, at the north-east of the bay of Carrickfergus, in the county of Antrim.

WHITEHORN, a royal borough and market-town in the district of Machers, and shire of Wigtown, Scotland, is situated on the western side of the bay of Wigtown, at the distance of 116 miles S.S.W. from Edinburgh. It is a place of great antiquity, having been the Roman station *Leucophibia*, or *Candida-Casa* of Bede, and the capital of the Novantes, who possessed all Galloway beyond the river Dee; and it was so early the seat of religion, that, according to Pinkerton, the bishopric of Galloway, or Whitehorn, is the oldest in Scotland. The cathedral, of which there are now scarcely any remains, was founded in the fourth century by St. Ninian. A priory of the Premonstratensian order was also early founded here, and richly endowed by Fergus, lord of Galloway. The borough now consists chiefly of one large well-built street, extending from north to south, intersected by several smaller. A rivulet, over which is a neat bridge, runs across the main street. Near the centre of the town is a respectable hall for public meetings, adorned with turrets and a spire, and furnished with a set of bells. Whitehorn is governed by a provost, two bailties, and fifteen counsellors; and unites with the boroughs of New Galloway, Wigtown, and Stranraer, in

sending a representative to the imperial parliament. A weekly market is well supplied. The tanning of leather has been carried on several years to a considerable extent, and some cotton manufactures have been commenced. The parish of Whitehorn extends eight miles in length and four in breadth, and occupies that extremity of the peninsula of the shire of Wigtown which is formed by the bays of Wigtown and Luce. The soil is in general fertile, and the farms well cultivated. Here are many extensive plantations in a flourishing condition; considerable quarries of variegated marble and strong slate; and promising appearances of lead and copper mines, but none have as yet been worked. The extent of sea-coast is about nine miles. The isle of Whitehorn, included in the parish, has a safe harbour, and a village containing 350 inhabitants. According to the return of the year 1811, the population of the whole parish was 1935.—*Beauties of Scotland*, vol. ii. Wigtownshire. *Carlisle's Topographical Dictionary of Scotland*, vol. ii. 1813.

WHITEHORN, a small island of Scotland, near the south-east coast of the county of Wigtown. N. lat. $54^{\circ} 46'$. W. long. $4^{\circ} 27'$.

WHITEHURST, JOHN, in *Biography*, was born at Congleton, in Cheshire, in 1713, and brought up to the trade of his father, who was a watch-maker. At the age of 21 years he visited Dublin, in order to acquaint himself with the construction of a curious clock; but being disappointed, he engaged in business for himself at Derby, about two or three years after his return, where he distinguished himself by a variety of ingenious pieces of mechanism; and he thus established a reputation, which caused him to be consulted by all persons who wished to avail themselves of superior skill in mechanics, pneumatics, and hydraulics. In 1775 he was appointed, without any solicitation on his own part, stamper of the money weights; which office required his removal to London, where he spent the remainder of his days, and where his house was the resort of scientific men of various descriptions. In 1778 he published his "Inquiry into the original State and Formation of the Earth," of which an enlarged and improved edition appeared in 1786, and a third in 1792. In May 1779 he was elected a fellow of the Royal Society. In 1783 he visited Ireland, to examine the Giant's Causeway, and the northern parts of the island; and the result of his inquiries was annexed to his work above-mentioned. In the course of his journey he erected an engine for raising water from a well to the summit of a hill, in a bleaching-ground at Tullidoi, in the county of Tyrone. It is worked by a current of water, and is of very curious construction. In 1787 he published "An Attempt towards obtaining invariable Measures of Length, Capacity, and Weight, from the Mensuration of Time." (See STANDARD.) Mr. Whitehurst, having been for some time subject to the gout, was at length carried off by a paroxysm of it in the stomach, in February 1788, in the 75th year of his age, at his house in Bolt-court, Fleet-street. As a man of science, he was much respected by all who knew him; but he was still more estimable on account of his moral qualities. In his dress he was plain, temperate in his diet, and in his general intercourse with mankind easy of access, benevolent in his disposition, and obliging in his manners. His papers on Chimneys, Ventilation, and Garden-stoves, were collected and published in 1794 by Dr. Willan. His papers in the *Philosophical Transactions*, printed afterwards in the collection of his works in 1792, were the following: *viz.* "Thermometrical Observations at Derby," in vol. lvii.; "An Account of a Machine for raising Water at Oulton in Cheshire," vol. lxxv.; and "Experiments

periments on ignited Substances," vol. lxvi. Hutton's Math. Dict.

WHITEKIRK, in *Geography*, a parish and village of Scotland, in the county of Haddington; 4 miles S.E. of North Berwick.

WHITELAND, WEST. See *WEST Whiteland*.

WHITELICK, a town of the state of Kentucky; 13 miles S. of Stamford.

WHITELock, BULSTRODE, in *Biography*, a lawyer and statesman, was born in London in the year 1605, and finished his education as a gentleman-commoner of St. John's college, Oxford. Being destined for the profession of the law, he pursued the study of it under the direction of his father, Sir James Whitelock, who was one of the justices of the King's Bench. As he had a taste for the fine arts, he was nominated as one of the chief managers of the royal masque presented by the inns of court to Charles I. and his queen in 1633, of which he has given a florid description. He became soon distinguished in his profession at the bar, and was frequently consulted by Hampden, when he was under prosecution for resisting the imposition of ship-money. In 1640 he was elected as a representative for Marlow in the Long parliament; and though his principles were favourable to the measures which then engaged the public attention, he concurred with Selden and others in deprecating a resort to arms; but when the house had determined for war, he accepted the post of deputy-lieutenant for the counties of Oxford and Buckingham, and appeared at the head of a gallant company of horse raised among his neighbours. Nevertheless he was always averse from a civil contest; and in January 1642-3, he was one of the commissioners appointed to treat of peace with the king at Oxford; and in 1644 he was one of those who presented to the king propositions of peace agreed upon in parliament; and the king's answer was, at his majesty's request, drawn up by him and Holles, for which they were accused of high treason by parliament, but extricated themselves with honour. As a member of the assembly at Westminster for settling the form of church government, he avowed himself in opposition to the divine right of presbytery. He also opposed the power of excommunication assumed by the Presbyterians; being always, like Selden, an enemy to violent exertions of church power by any party; and he was an invariable advocate of legal rights, and an opposer of arbitrary power, assumed or exercised in either house of parliament. When he became suspected by the parliamentary leaders, he joined the army-party, and opposed the measure of disbanding the troops, which was proposed by some of his former associates. When it was determined to bring the king to trial, he was nominated as one of the committee for drawing up the charge; but this was a business in which he did not choose to engage. However, he had no objection against taking an active part under the new government, and he was nominated in February 1648-9 one of the council of state. In some other instances he incurred the charge of inconsistency, as he complied with measures which he did not approve. To Cromwell he was so agreeable, that he was one of the four members of parliament appointed to meet him after his famous victory at Worcester in 1651. Whitelock avowed himself steadily attached to monarchy, as a part of the state which could not be dispensed with, and as interwoven with the laws of the country; and he therefore suggested, that the late king's eldest or second son should be sent for, and enter into terms for securing the liberties of the nation. Upon the dissolution of parliament by Cromwell, though he had previously resisted the attempts of the army to govern without the parliament, he obsequiously performed the

functions of his office under the new establishment. The usurper, however, regarded him with distrust, and would not admit him into his first or little parliament. His commission of the seals was superseded by the suppression of the court of chancery; and he was therefore glad to be occupied in a station which would not require his interference in party contests, which was that of ambassador from England to queen Christina of Sweden. Upon his departure, Cromwell assumed the title and authority of lord protector, and issued his instrument of government, which Mr. Whitelock had concurred in preparing, and which was afterwards found by Cromwell incompatible with his usurpation. Having concluded an advantageous treaty with queen Christina, who received him in November 1653 with distinction, he returned to his own country, and resumed the office of commissioner of the great seal, upon the restoration of the court of chancery; and he was returned as a representative for three counties in Cromwell's second parliament. Upon Cromwell's regulation and limitation of the court of chancery, he again resigned the custody of the seal; and as some compensation for his loss, he was appointed a commissioner of the treasury. He was free and faithful in giving salutary advice to the Protector, and nevertheless retained his confidence. Declining the office of ambassador to Sweden, which was offered him, he acted as one of the commissioners to treat with the Swedish ambassador in England. He was returned for Buckinghamshire in Cromwell's third parliament, and officiated for some time as speaker. Although he would not present to parliament the "Humble Petition and Advice," which was intended to empower Cromwell to assume a higher title than that of Protector, he was chairman of the committee for conferring with him about it; and he concurred in the request that he would adopt the royal title. Whitelock contracted so decidedly in Cromwell's interest, that he was one of those who were called by him to the upper house; but he declined being governor of Dunkirk, and also the honour of being created a viscount. During the short protectorate of Richard, Whitelock acted as one of the keepers of the great seal; and when the army set up a republican government, he was nominated one of the council of state; and as its president, he joined in all the measures that were adopted for upholding the tottering frame of government, on the principle that if no legal authority was acknowledged, the sword alone would probably govern. When Monk proposed to restore the remains of the Long parliament, Whitelock took a commission from the committee of safety for raising a regiment of horse, and urged Lambert to march against that leader. But the design failing, and the parliament meeting, he just appeared in pursuance of the speaker's summons; and as he had reason for suspecting a design to apprehend him, he returned to a friend's house in the country, and sent the great seal by his wife to the speaker;—and thus terminated his public life. Upon the Restoration, he had the good fortune to escape a bill of pains and penalties in the house of commons, only by the negative of a small majority. After having passed fifteen years in retirement, chiefly at Chilton-park in Wiltshire, he there died in January 1676; leaving a numerous family, after having been twice married.

Possessed of considerable abilities, and of distinguished talents for business, he would have claimed a more general and cordial respect, if he had not been a temporizer in his public conduct. His principles of government appear, however, to have been good, and in his temper he was averse from every kind of violence and injustice. He was a well-wisher to the law and constitution, and supported them as far as it was consistent with his interest and safety. In all private

private concerns he maintained an estimable character for probity and honour. After his death an anonymous editor, in 1682, published his "Memorials of the English Affairs; or, an historical Account of what passed from the Beginning of the Reign of King Charles I. to King Charles II. his happy Restoration," fol.; an improved edition of which appeared in 1732. From his MSS. were published in 1709, "Memorials of the English Affairs from the supposed Expedition of Brute to this Island, to the End of the Reign of King James I.," a chronological epitome of history for his own use. In 1766 Dr. Charles Morton, secretary to the Royal Society, published "Whitelock's Notes upon the King's Writ for choosing Members of Parliament, 13 Car. II. being Disquisitions on the Government of England by King, Lords, and Commons," 2 vols. 4to. The same editor also published in 1772, "A Journal of the Swedish Embassy in the Years 1653 and 1654, from the Commonwealth of England, Scotland, and Ireland; written by the Ambassador the Lord Commissioner Whitelock; with an Appendix of original Papers," 2 vols. 4to. Biog. Brit. Gen. Biog.

The commissioner, amid all his grave affairs, found leisure to cultivate music, of which he was very fond; and seems to have interested himself in all the remarkable performances of his time. During the happy days of Charles I., masques were so frequent at court and elsewhere, that in 1633 no less than five masques were performed at different places before the king and queen. See MASQUE.

A very circumstantial account of one of these, "The Triumphs of Peace," has been left to his family by the commissioner himself, which was in the possession of the late Dr. Morton of the British Museum. The musical part of this performance seems to have been wholly assigned by the benchers at the Temple to commissioner Whitelock. For in his narrative he says, "I made choice of Mr. Symon Ives, an honest and able musician, of excellent skill in the art, and of Mr. Lawes, to compose all the aiers, lessons, and songs for the masque, and to be masters of all the musick under me." See IVES, and LAWES, WILLIAM.

The commissioner, besides being a performer, was a bit of a composer; as he says with great triumph at the latter end of his narrative: "I was so conversant with the musitians, and so willing to gaine their favour, especially at this time, that I composed an aier myselfe, with the assistance of Mr. Ives, and called it 'Whitelocke's Coranto;' which being cried up, was first played publicly, by the Blackefryar's musicke, who were then esteemed the best of common musitians in London. Whenever I came to that house (as I did sometimes in those dayes), though not often, to see a play, the musitians would presently play 'Whitelocke's Coranto;' and it was so often called for, that they would have it played twice or thrice in an afternoon. The queen hearing it, would not be persuaded that it was made by an Englishman, because she said it was fuller of life and spirit than the English aiers use to be; butt she honoured the 'Coranto' and the maker of it with her majestyes royall commendation. It grew to that request, that all the common musitians in this towne, and all over the kingdome, gott the composition of it, and played it publicly in all places, for above thirtie years after."

Among other moral reflections, addressed to his family, on such vanities as he had been describing, lord commissioner Whitelock adds: "Yet I am farre from discommending the knowledge of this art (music), and exercise of this recreation for a diversion, and so as you spend not too much of your time in it, that I advise you in this as in other accomplishments, that you endeavour to gett to some per-

fection, as I did, and it will be the more ornament and delight to you."

The lord commissioner inserts his aier, in order to preserve it for the use of his family, if any of them should delight in it. This "Coranto" may be seen in Burney's Hist. Mus. vol. iii.; and the whole narrative of the masque, entitled "The Triumph of Peace," from "Whitelock's Labours remembered in the Annales of his Life, written for the Use of his Children," MS.

WHITEMARSH, in *Geography*, a township of Pennsylvania, in the county of Montgomery, with 1328 inhabitants; 15 miles N.W. of Philadelphia.

WHITEN HEAD, a cape on the north coast of Scotland. N. lat. 58° 37'. W. long. 4° 22'.

WHITENESS, a town of the island of Shetland; 6 miles N.W. of Lerwick.

WHITENING of Bones, for a skeleton. See BONE.

WHITENING of Cloth. See BLEACHING.

WHITENING of Hair. See HAIR.

WHITENING of Wax. See WAX.

WHITEPAINE, in *Geography*, a town of Pennsylvania, in the county of Montgomery, with 955 inhabitants; 20 miles N.W. of Philadelphia.

WHITE-PLAINS, a post-township and half-shire town of West Chester county, in New York; 30 miles from New York, and 140 S. of Albany. The whole area of this town is about 8½ square miles; and its population, in 1810, was 693, with 68 electors, and 109 taxable inhabitants. The village of White-plains is pleasantly situated on a fine plain, three-quarters of a mile E. of Bronx creek, and contains a court-house, prison, and a handsome collection of houses. The American troops were defeated in this place, by the British under general Howe, in the year 1776.

WHITESAND BAY, a bay on the W. coast of England, in the county of Cornwall, a little to the N. of the Land's End. N. lat. 50° 6'. W. long. 5° 34'.—Also, a bay on the W. coast of Wales; 1 mile N.W. of St. David's.

WHITESEA, a large gulf of the North Frozen sea, on the N. coast of Russia, bounded on the N.E. and S. by the government of Olonetz, in the vicinity of Archangel, extending from N. to S. within the land, from 69° to 63° of N. lat., and containing a number of small islands.

WHITETOWN, the principal town and half shire of the county of Oneida, in the state of New York, situated on the Mohawk river, 95 miles N.W. of Albany; including Utica, and having three post-offices. Its form is irregular, and area about 40 square miles. In January, 1785, Mr. Hugh White, from Connecticut, with a young family, became the first settler. In 1788 the town of German Flats was divided, and a new town erected, and named Whitetown, in honour of Mr. White. In 1798 the county of Oneida was established, by a subdivision of Herkimer, and Whitetown included within this county. By subsequent divisions, Whitetown was reduced to a medial measure of 9 miles by 8. It is situated immediately on the great thoroughfare between Albany and the Western lakes; between Canada and the principal commercial sea-ports of the American states on the Atlantic ocean. This town contains three large post-villages, Utica incorporated, Whitesborough, and New Hartford. Whitetown, including these villages, is unrivalled, in the United States, with regard to wealth, population, trade, and improvements, among inland towns of such recent settlement; and none in this state, of the same area, affords so great a population. It has seven principal churches; one Episcopal, three Presbyterian, two Baptist, in one of which the service is performed

formed in the Welsh language, and one of Welsh Independents, besides some smaller houses dedicated to the same purpose. Here are three grammar-schools, one in each village, and many common schools. It has also a cotton manufactory. This town has been gradually enlarged and embellished. Its population, by the census of 1810, is 4912, with 533 senatorial electors.

WHITEWATER, a township of Ohio, in Henieton county, with 910 inhabitants.—Also, a river of Scotland, which runs into the Esk, in the county of Forfar.

WHITGIFT, JOHN, in *Biography*, an English prelate, was born at Great Grimby, Lincolnshire, in 1530, and in 1548 entered at Queen's college, Cambridge, from which he removed to Pembroke-hall, where he enjoyed the tuition of John Bradford, afterwards one of the Protestant martyrs. In 1555 he became a fellow of Peter-house, and in 1557 commenced M.A. Upon the visitation of the university by cardinal Pole, about this time, for the purpose of purging it of reputed heretics, Whitgift dreaded the search; but by favour of the vice-chancellor escaped, and remained in the university. Upon the accession of queen Elizabeth, he entered into orders in 1560, and obtained preferment from Dr. Cox, bishop of Ely. In 1563 he was appointed Margaret professor of divinity, and chaplain to the queen in 1565. Continuing in the university, and maintaining the character of a good preacher and vigorous disciplinarian, his salary as professor was advanced, and a licence was granted him to preach in any part of the realm. In 1567 he was made master of Pembroke-hall, and soon after regius professor of divinity. He next became master of Trinity college, and graduated D.D.; and on his appointment to keep the commencement-act, he chose for his thesis "The Pope is the Antichrist." In 1570 he formed a body of statutes for the university; in consequence of which the heads of houses gained new powers, by the exercise of which he deprived Cartwright, an eminent Calvinistic divine, of his Margaret professorship. In 1571 he was vice-chancellor of the university, in the exercise of which office he manifested so much zeal for the established church, that the queen conferred upon him the deanery of Lincoln, besides other dignities and honours. He also expelled Cartwright from his fellowship, and carried on a controversy with that divine and other Puritans in general. In 1577 he was advanced to the see of Worcester, and the office of vice-president of the council for the marches of Wales. Upon his advancement to the prelate, he resigned his mastership of Trinity college, and devoted himself to the duties of his new office, taking care to improve its revenues; and in the exercise of a power, which he obtained from the crown by the interest of lord Burleigh, to bestow the prebends of his church on his own friends according to his own selection. His zeal, however, against popish recusants, which was thus recompensed, and which he exercised without due discrimination in the execution of his office as vice-president of Wales, involved him in disputes with the other judges, and offended the president, sir Henry Sydney, so that on his return from Ireland, where he was lord-deputy, he discharged Whitgift from his post. As he occupied new stations, his reputation as a man of business increased; and in 1582 he was nominated by the archbishop of Canterbury, Grindal, chief commissioner for settling disputes in the dioceses of Lichfield and of Hereford. Grindal's remissness in executing the laws against the non-conforming clergy displeased the queen, and caused her to suspend him from his functions; and on his death in 1583, Whitgift, who had secured her favour by his zeal for the church and hostility to the Puritans, was appointed to succeed him. He did not disappoint her expectations; but

engaged her to issue a new ecclesiastical commission, more arbitrary and possessing more extensive authority than any former one. Its jurisdiction extended over the whole kingdom, and comprehended all orders of men; and as Hume describes it, "every circumstance of its authority, and all its methods of proceeding, were contrary to the clearest principles of law and natural equity." "In a word," says he, "this court was a real *inquisition*, attended with all the iniquities, as well as cruelties, inseparable from that tribunal." The measures of Whitgift were in unison with the constitution and spirit of this commission; and the council itself interposed to moderate them. In reply to the remonstrance of the council in favour of some ministers of Ely, who had been suspended for refusing to answer interrogatories, he said, "Rather than grant them liberty to preach, he would choose to die, or live in prison all the days of his life." To the queen he recommended "suppressing" the discipline proposed by the Puritans, "rather than confuting it by writing;" and he advised that a restraint should be laid upon the liberty of the press at Cambridge. It is no wonder that by such conduct he should become the object of great aversion to the puritanical party. Accordingly he was very acrimoniously attacked in a pamphlet, entitled "Martyn Marprelate," in which he was compared to the most ambitious and tyrannical churchmen of former times. Whitgift, however, blended with the violence of his temper some degree of kindness and good humour. This was manifested in his conduct towards Cartwright. In his charities he was munificent, and in his mode of living hospitable, as well as splendid and ostentatious. In 1595 he laid the foundation of a hospital at Croydon, on which very large sums were expended. He maintained several students at the university, and entertained for many years at his palace several refugee divines, that had been recommended to him by Beza and others. His house, it is said, was as much an academy for martial exercises as a school for letters. "On his progresses he was attended by a numerous and splendid train; and at his first journey into Kent he rode into Dover with one hundred of his own servants in livery, of whom forty were gentlemen wearing gold chains. On festival days he was served with great solemnity, sometimes on the knee; and public worship in his chapels was performed with every circumstance of religious pomp. This external grandeur exalted the church of England in the eyes of foreigners, who had been led to imagine that the Reformation in this country had degraded the ecclesiastical establishment as much as it had done in some others."

Upon the accession of king James, Whitgift felt some alarm under the apprehension of some changes in the liturgy; and it has been supposed that his agitated state of mind concurred with the debility of age, and the operation of some other causes, in producing the paralytic attack which terminated his life in February 1603-4. A monument was erected to his memory at Croydon, where he was interred. Whitgift was neither a man of learning, the Latin language bounding his classical literature, nor a profound theologian. He was principally distinguished by his vigour and activity as a man of business. As a preacher he was popular; and this talent in which he excelled laid the foundation of his advancement. *Biog. Brit. Hume's Hist. Gen. Biog.*

WHITING, in *Ichthyology*, the English name of a common fish of the *afellus* kind, commonly distinguished by the writers in ichthyology by the name of *afellus mollis*, though by some called *afellus albus* and *merlangus*.

The whiting, or gadus merlangus of Linnæus, is a fish of an elegant form; the upper jaw is the longest; the eyes are large, the nose sharp, and the teeth of the upper jaw long,

long, appearing above the lower when closed: the first dorsal fin has fifteen rays, the second eighteen, and the last twenty. The colour of the head and back is a pale brown; the lateral line white and crooked; the belly and sides silvery; the last streaked lengthways with yellow.

Whitings appear in large shoals in our seas in the spring, keeping at the distance of about half a mile to that of three miles from the shore. They are the most delicate and wholesome of any of the genus; and seldom grow to more than ten or twelve inches in length. Pennant.

No whiting is to be taken in the Thames or Medway of less size than six inches from the eye to the end of the tail, or at any time except from Michaelmas-day to Ember week. (30 Geo. II. cap. 21.) Nor under six inches any where else. 1 Geo. I. stat. 2. cap. 18.

WHITING-POLLACK. See *GADUS Pollachius*, and POLLACK.

WHITING-POUT. See POUTING, and *GADUS Barbatus*.

WHITING, in *Geography*, a township of Vermont, in the county of Addison, with 565 inhabitants; 25 miles N. of Rutland.

WHITING Bay, a small bay of the county of Waterford, Ireland, a little E. of Youghal bay.

WHITLEY, a township of Pennsylvania, in Greene county, with 1264 inhabitants.

WHITLOW, in *Surgery*, called also by surgeons *paronychia*, *panaritium*, *onychia*, &c. is an inflammation affecting one or more of the phalanges of the fingers, and generally terminating in an abscess. These are the parts which are the usual situation of the complaint; but sometimes a disease, which is precisely similar, makes its attack upon the toes. It is likewise to be understood, that in severe cases, the disorder extends itself to many other parts besides the finger, the matter making its way upward higher than the wrist. Thus, as Callisen justly observes, the skin, cellular substance, sheath of the flexor tendons, and less commonly that of the extensors, the tendons themselves, the annular and capsular ligaments, the periosteum, the very texture of the finger-bones, and the pulpy substance underneath the nail, are all parts to which a whitlow may extend its mischievous consequences.

From what has been already observed, it must be plain that whitlows differ very much in their degree of violence, and in their depth and extent. Hence, surgical authors usually describe four or five varieties of the complaint. The division adopted by Callisen comprehends five cases; namely, the *cutaneous* or *superficial paronychia*, the *subcutaneous paronychia*, the *paronychia of the tendons*, or *theca*, the *paronychia of the periosteum*, and the *subungual paronychia*, or that *situated underneath the nail*.

The *cutaneous paronychia* begins with a superficial inflammatory redness of the finger, and, as early as the second or third day from the commencement of the attack, the cuticle of the part affected becomes raised in the form of vesicles, which contain a limpid serum, but sometimes a bloody fluid. (Callisen, vol. i. p. 294.) Mr. Pearson describes the cutaneous paronychia as being seated at the end of the finger, immediately below the cuticle, and as sometimes surrounding the finger and root of the nail. The skin, he says, is very little discoloured. The case speedily advances to suppuration; and when this process is completed, the cuticle appears almost transparent. After the contents of this little abscess are evacuated, the ulcer seldom demands any particular attention. Principles of Surgery, p. 88. edit. 2.

The *subcutaneous paronychia* makes its appearance in the form of an inflammatory tumour, attended with a great deal of acute pain. The symptoms, however, are not alarming,

nor do they generally extend beyond the inflamed finger. In severe examples, the whole hand is more or less affected with pain and tension, and uneasiness is felt all up the arm. The severity of the pain, in such cases, frequently prevents sleep, and the whole system is thrown into some disorder. The attack of this kind of whitlow is attended with a more acute and throbbing pain than that of the cutaneous paronychia, suppuration proceeds more slowly, and matter is frequently formed under the nail. The disease is particularly situated in the cellular membrane under the cutis.

The *more deeply-seated kinds of whitlow* are those affecting the sheath of the flexor tendons and the periosteum, which parts, indeed, by reason of their vicinity to each other, are often both attacked together. The disease commences with an intense, burning, shooting, throbbing pain in the finger, accompanied with severe febrile symptoms. At first, no swelling whatsoever can be perceived in the part affected; but afterwards a slight œdematous tumour follows, which gradually assumes an inflammatory appearance, and the tumefaction spreads from the finger to the hand, and forearm, and even to the axilla. On the inner side of the arm, red hard streaks may also frequently be observed, which are inflamed absorbent vessels tending to the axillary glands, which are themselves sometimes enlarged and very painful. The pain of the whitlow is particularly felt shooting up from the affected finger to the inner condyle of the humerus, and thence to the arm-pit. Delirium, and other alarming symptoms, occasionally attend these worst descriptions of whitlows, which are alleged to have proved sometimes fatal. The matter, which is small in quantity, is either collected within the sheath of one of the tendons, or it is under the periosteum in contact with the bone, which is generally found in a carious state; and sometimes the superincumbent integuments suffer sphacelation. See Pearson's Principles, p. 90.

The *subungual paronychia*, or that which especially occurs under the nail, commences with inflammatory symptoms, which are, however, much less urgent and dangerous than those of the preceding case; and the situation of the disease renders its nature quite obvious.

The usual exciting causes of whitlows are various external injuries, as pricks, contusions, &c. The lodgement of a thorn or splinter in the part, is another frequent cause of these abscesses. They are, however, much more common in young healthy persons than in others; and they appear in many instances to occur spontaneously, that is to say, without our being able to assign any manifest cause for them. There is one particular sort of whitlow, which Mr. Pearson has thought proper to call *venereal*, as will be presently noticed.

With regard to the prognosis in ordinary examples of the complaint, it may be laid down that the cutaneous and subcutaneous paronychiæ are in general unattended with danger. But those whitlows which are formed within the theca of the flexor tendon, if they be not relieved by the timely interference of surgery, very often produce abscesses, extending up the hand and arm, in the course of the corresponding tendon and muscle, which parts become so altered and diseased, that their functions are permanently injured, and the bones of the finger destroyed by necrosis. When also the periosteum is affected, the matter lying underneath, or closely upon it, the neighbouring phalanx of the finger generally perishes. Whitlows beneath the nail frequently occasion a loss and separation of the part.

The indications in the treatment of whitlows are;

1. To endeavour to produce an early resolution of the inflammation; but as this attempt seldom succeeds, and the case almost proceeds to suppuration,

2. The

WHITLOW.

2. The great desideratum is to discharge the matter as soon after its formation as possible.

3. The last thing is to heal the wound.

With respect to the first indication, experience proves, that the inflammation, in a very early stage of the complaint, may sometimes be dispersed by the adoption of ordinary antiphlogistic treatment. Here topical bleeding, especially the prompt and repeated application of leeches to the painful part several times in the day, is highly commendable; and the inflamed finger and hand may be covered with a cold, discutient, saturnine lotion, together with which means some writers advise the whole limb to be bound with a circular roller. Others speak lightly of the good effects of an early immersion of the affected finger in very warm water, or in lotions made of alcohol, vinegar, oil of turpentine, &c. and used as hot as can be borne. Callisen states, that he has also frequently observed great benefit arise from the affusion of such lotions on the part. He even asserts, that the pain and more deeply-seated inflammation of the finger may be sometimes checked by applying caustic or a blister to the integuments. When the patient's sufferings are very great, the exhibition of opium is indispensable after bleeding has been duly practised. The same writer also affirms, that electricity has been found useful at the very commencement of a whitlow.

When two days elapse without any probability of resolution taking place, suppuration ought to be promoted by the immediate and continued use of emollient poultices and fomentations. Nor should the surgeon wait for the abscess to point, but make an opening with less loss of time, in proportion as the case becomes worse. In examples where the pain is exceedingly violent, the incision should not be deferred beyond the fourth day from the beginning of the pain. The opening ought also to be made at the part which was first painful, and thence the cut should be continued longitudinally, and as deeply as the situation of the matter. The lancet, indeed, if requisite, must be introduced down to the bone, by which means a small quantity of deeply-seated confined matter may frequently be voided, and the pain and progress of the disease at once stopped. Even when no matter is discharged from the opening, an early incision sometimes speedily relieves very severe cases of whitlow; probably (as Callisen observes) on the principle of removing tension, and occasioning hemorrhage from the part. In those instances, in which an incision has not been practised in due time, and the matter under the tendinous sheath has spread extensively up the hand and arm, it is sometimes necessary to make the opening free and ample, without injuring, however, the annular ligament. The discharge of the abscess, and the evacuation of blood from the incision, are followed by almost immediate relief. When the matter is lodged under the periosteum, the bone is mostly found affected with necrosis. In cases of this description, there are some practitioners who prefer the removal of the diseased phalanx, to awaiting a tedious and uncertain cure by the processes of nature. Callisen, however, informs us, that he has often seen the dead portion of the bone exfoliate, leaving the rest in a state of preservation.

When a whitlow under the nail cannot be dispersed, the matter should be let out by an opening, practised through the transparent part of the nail, or by the side of it. Some surgeons adopt the plan of scraping the nail, so as to render it as thin as possible, before they cut through it, which is an ingenious and commendable method. See Callisen's *Syst. Chir. Hod.* t. i. p. 293. 295.

In the fifth volume of the *Medico-Chirurgical Transac-*

tions, Mr. Wardrop has described a very inveterate and troublesome species of whitlow, which, from its malignant character, he has called the *onychia maligna*. "The commencement of this disease is marked by a degree of swelling, of a deep red colour, in the soft parts at the root of the nail. An oozing of a thin ichor afterwards takes place at the cleft, formed between the root of the nail and soft parts, and at last the soft parts begin to ulcerate. The ulcer appears on the circular edge of the soft parts at the root of the nail; it is accompanied with a good deal of swelling, and the skin, particularly that adjacent to the ulcer, has a deep purple colour. The appearance of the ulcer is very unhealthy, the edges being thin and acute, and its surface covered with a dull yellow, or brown-coloured lymph, and attended with an ichorous and very fetid discharge. The growth of the nail is interrupted, it loses its natural colour, and at some places appears to have but little connection with the soft parts. In this state (says Mr. Wardrop), I have seen the disease continue for several years, so that the toe or finger became a deformed bulbous mass. The pain is sometimes very acute; but the disease is more commonly indolent, and accompanied with little uneasiness. This disease affects both the toes and the fingers. I have only observed it on the great toe, and more frequently on the thumb, than any of the fingers. It occurs, too, chiefly in young people; but I have also seen adults affected with it."

With regard to the treatment of the species of whitlow named by Mr. Wardrop *onychia maligna*, all local applications have in many instances proved quite ineffectual, and the part been amputated. The only local treatment which Mr. Wardrop has ever seen relieve this complaint has been the evulsion of the nail, and afterwards the occasional application of escharotics to the ulcerated surface. We have seen a similar plan occasionally succeed, and the applications which appeared to answer best were, arsenical lotions, Plunket's caustic, or a very strong solution of the nitrate of silver. Nothing, however, will avail till the nail is removed, and its total separation sometimes takes up a good deal of time, unless the patient submit to the great pain of having it cut away.

Mr. Wardrop tried with success the exhibition of mercury in four cases of the *onychia maligna*. The medicine was given in small doses at first, and afterwards increased, so as to affect the gums in about twelve or fourteen days. The fores in general soon assumed a healing appearance when the system was in this state, and the bulbous swelling gradually disappeared. Wardrop in *Medico-Chir. Transf.* vol. v. p. 135, &c.

Mr. Pearson has published an account of a peculiar sort of whitlow, to which he affixes the epithet *venereal*. He observes, that it generally appears in the form of a smooth, soft, unresisting tumour, of a dark red colour, and is situated in the cellular membrane about the root of the nail. It is attended with an inconsiderable degree of pain in the incipient state; but as suppuration advances, the pain increases in severity. The progress of the abscess to maturation is generally slow, and is seldom completed.

When the matter is evacuated, the nail is generally found to be loose, and a very foul but exquisitely sensible ulcer is exposed; and considerable sloughs of cellular membrane, &c. come away, so as to render the fore sometimes very deep. The discoloured and tumid state of the skin commonly extends along the finger, considerably beyond the margin of the ulcer. In such cases, the integuments of the finger become remarkably thickened, and the cellular membrane is so firmly

firmly condensed, as not to permit the skin to glide over the subjacent parts. The bone is not usually found in a carious state.

According to the same author, this species of whitlow is more frequently seen among the lower class of people, when they labour under lues venerea, than in the higher ranks of life. It does not appear to be connected with any particular state of the disease, nor is it confined to one sex more than the other. In the Lock Hospital, it is said to occur in the proportion of one patient in five hundred.

In adopting the name of *venereal paronychia*, Mr. Pearson informs us, that it is not with the design of implying that the case is a true venereal abscess, the matter of which is capable of communicating syphilis to a sound person. Its progress and cure, he observes, seem to be unconnected with the increased or diminished action of the venereal poison in the constitution, and to be also uninfluenced by the operation of mercury. Mr. Pearson considers the venereal disease as a remote cause, which gives occasion to the appearance of this as well as of several other diseases, which are widely different from its own specific nature.

In the incipient state of the venereal whitlow, when no severe symptoms are present, Mr. Pearson thinks it best to use no external applications, and merely cover the part with a bit of fine rag. The disease will then often gradually disappear of itself, without coming to suppuration. When matter is formed, Mr. Pearson says, the abscess may be permitted to burst spontaneously. Every species of dressing will frequently be found to give great pain, and disagree with the sore. The same writer, however, states, that one application, composed of equal parts of the balsam of copaiva and tinctura thebaica, may sometimes be used with a good effect. The principal object is to keep the patient as easy as possible, by the internal use of opium, until the sloughs are separated, and the ulcer becomes clean. It may then be treated as a common sore: Peruvian bark will also be generally proper. In the thickened diseased state of the integuments, Mr. Pearson condemns amputation, as being likely to produce a stump, which will change into a sore, resembling that for which the operation was performed. See Pearson's Principles of Surgery, edit. 2.

It is not at all clear to us, that Mr. Wardrop's case, which he terms the onychia maligna, is not actually the same disease as what Mr. Pearson has named the venereal whitlow. The only doubt arises from the former gentleman's recommending the exhibition of mercury as a means of cure; while the latter declares, that the complaint is quite uninfluenced by the operation of this medicine. We confess, that although some hundreds of cases of very bad whitlows have fallen under our observation, we have never met with any instance in which the cure seemed to require mercury.

WHITLOW in the Feet of Sheep, in *Rural Economy*, a disease that takes place in the latter end of summer, and which is more frequent among the long than the short sort of sheep. It but seldom happens in clean sheep-walks, though it is very troublesome on soft, dirty, pasture-lands. It is frequently occasioned in the milking season, by the boughts or folds being dirty, and by the sheep being confined in the old houses. It is of the inflammatory nature, and commonly affects the fore-feet, but sometimes all four. The outer part of the hoof is the usual seat of the disease, and from the cleft a sharp fetid humour exudes, sometimes engendering maggots, and corroding the flesh, nay even the bone. All around the hoof there is an inflammation, which turns black, and this part sometimes drops off. It is a very painful affection, so much so, that the animal often crawls.

As the weather gets more cold, it commonly becomes better, but it still walks in a lame manner.

On the appearance of the disease the foot is to be examined, and the diseased part opened to let out the acrid matter. It is then to be washed well, and dressed with mercurial ointment and sulphur in mixture, or tar with red precipitate, binding it up with a flannel bandage, to preserve it warm and clean. In case it does not take on suppuration, but degenerates into a foul and tedious ulcer, such applications as spirit of turpentine and sulphuric acid may be proper. And in all cases the sheep should be kept in a clean, easy, dry pasture, until it becomes well. See FOOT-ROT.

WHITLOW-GRASS, or Mountain Knot-Grass, in *Botany*. See PARONYCHIA, or ILLECEBRUM.

WHITLOW-GRASS is also a name given to some species of draba.

WHITLOW-GRASS, Rue-leaved, a species of saxifrage.

WHITSTABLE, in *Geography*, a village and sea-port of England, in Kent, near the mouth of the Swale. Here is a considerable oyster-fishery, which employs upwards of 70 boats. Some colliers likewise bring hither coals for Canterbury and the neighbourhood; 7 miles N. of Canterbury. N. lat. $51^{\circ} 22'$. E. long. $1^{\circ} 21'$.

WHITSUN ISLAND, an island in the South Pacific ocean, discovered by captain Wallis on Whitsun-eve, in the year 1767, about four miles long and three wide, surrounded by a reef. The boat's crew got some cocoa-nuts, and some scurvy-grass: they met with none of the inhabitants, but some huts and several canoes building. No anchoring place for the ship could be discovered. S. lat. $19^{\circ} 26'$. W. long. $137^{\circ} 56'$.

WHITSUN, or Whitsunday Island, or Pentecost, one of the New Hebrides, in the South Pacific ocean, about thirty miles in length, and eight in breadth. S. lat. $15^{\circ} 44'$. E. long. $168^{\circ} 20'$. See NEW HEBRIDES.

WHITSUN Farthings. See PENTECOSTALS.

WHITSUNDAY'S PASSAGE, in *Geography*, a strait so called by captain Cook, from the day on which he failed through it, in 1770; between Cumberland island and the coast of New Holland.

WHITSUNTIDE, the fiftieth day after Easter.

The season properly called *Pentecost*, is popularly called *Whitsuntide*; some say, because in the primitive church, those who were newly baptized came to church between Easter and Pentecost, in white garments.

WHITSUNTIDE Bay, in *Geography*, a bay on the north coast of the island of Kodiack, west of Cape Whitsunday.

WHIT-TAWER, in *Rural Economy*, a provincial term applied to a collar-maker for team-horses.

WHITTINGHAM, in *Geography*, a town of Vermont, in the county of Windham, with 1248 inhabitants; 16 miles E. of Bennington.

WHITTLE, a provincial name applied to a sort of pocket or sheathed knife.

WHITTLEBURY FOREST, in *Geography*, a royal forest of England, in Northamptonshire.

WHITTLESEA MERE, a lake of England, in the county of Huntingdon, formed by a branch of the river Nen, situated to the S.E. of Peterborough.

WHITTLESEY, or WHITTLESEA, a town in the north part of the hundred of Witchford, Isle of Ely, and county of Cambridge, England, is situated on the confines of Northamptonshire and Lincolnshire, at the distance of 10 miles W.S.W. from the town of March, and 5 miles E. by N. from Peterborough. It contains two parishes, St. Mary's and St. Andrew's; but their boundaries cannot be distinctly

distinctly ascertained, and they are so far consolidated, that, though in separate patronage, the two livings are generally held by the same person; and only one register of births and burials is kept for both. Whittlesey formerly had a market; but when or by whom granted, there are no existing records. The market-day was Friday; but it has long been gradually falling into disuse, and since the year 1788 has been wholly discontinued. An annual fair for horses is still held. Each parish has a church, in which are various sepulchral memorials of ancient families. St. Andrew's church was given to the monks of Ely in the twelfth century, by Nigellus, second bishop of that see, for the purpose of augmenting their library, or, as it is expressed by an historian of that time, "making books for the library." At the west end of St. Mary's church is a very handsome tower, surmounted by a tall and elegant spire, which from its height constitutes a very conspicuous object from distant parts of this flat country. The tower is much ornamented with niches, pinnacles, and quaterfoils; and each angle of the octangular spire, which connects with the angular pinnacles of the tower by flying buttresses, is adorned with foliated crockets. There is in the town a charity-school for the instruction of twenty-seven children, and several almshouses.

Whittlesey, exclusive of the town, is divided into five districts, named Ellry, Cotes, Eldernal, Willow-hall, and Glassmoor. At Eldernal was a chapel, consecrated in 1525, but long since dilapidated. At Glassmoor were found, about the year 1742, several Roman lamps made of the red ware. The population of the whole, in the return of the year 1811, is stated to be 4248, occupying 729 houses. Lysons's *Magna Britannia*, vol. ii. Cambridgehire, 1808.

WHITTON, a town of England, in Lincolnshire, on the side of the Humber; 15 miles N.N.W. of Glamford Briggs.

WHOLAGUNGE, a town of Hindoostan, in Oude; 12 miles N.E. of Fyzabad.

WHOLDYACHUCK, a lake of North America. N. lat. 60° 20'. W. long. 109° 30'.

WHOLE, TOTUM, in *Arithmetic*, &c. See PART, DIVISION, PARTITION, &c.

WHOLE, in *Logic*, is distinguished into four kinds; viz. a *metaphysical*, when the essence of a thing is said to consist of two parts, the genus and the difference; *mathematical* or *integral*, when the several parts which go to make up the whole are really distinct from one another, and each of them may subsist apart; *physical* or *essential*, usually denoting and including the two essential parts of man, body and soul, but more properly including all the essential modes, attributes, or properties, contained in the comprehension of any idea; and *logical*, called also *universal*, the parts of which are all the particular ideas to which this universal nature extends. Watts's *Logic*, p. 117.

WHOLE *Blood*, *Measure*, *Number*, and *Sine*. See the substantives.

WHOLE *Milk-Cheese*, in *Rural Economy*, a term used to signify such cheeses as are made from the whole meal of milk, in contradistinction to those which are made from a part of it only. It is observed in the Gloucester Report on Agriculture, that coward-cheese ought to be made of the whole meal of milk; but in a dairy of twenty cows, it is not unusual to set by a pan, of about seven or eight gallons, till the next milking, which is then skimmed, and added to the new meal, from which a similar quantity is taken as before. The cream thus laid by is made into milk-butter. Coward-cheeses are either thin, about eight

to the hundred; or thick, generally called double Gloucester, about four to the hundred, or even larger. The latter are made in May, June, and July, principally, and even as long as grass continues good in some dairies.

It is noticed, too, in the same sort of report for the county of Peebles, in Scotland, that in the sheep-farms there, where sheep's-milk cheese is made, the whole of that sort of milk is seldom employed; but that the whole of the cow's milk upon the farm is mixed with the sheep's milk. That the butter, during this period, being ill-tasted, is kept for mixing with the tar for smearing the sheep; and the milk is afterwards made into cheese. There are, in consequence, very few farms where cheese is made of entire sheep's milk; and that, from the various proportions of the admixture of cow's milk, there are few articles in commerce passing under one common denomination, of which the qualities are so various as those of sheep's-milk cheese. See DAIRYING, and CHEESE.

WHOLE-Moulding. The impropriety of continuing whole-moulding in the construction of ships, has been pointed out in the article SHIP-BUILDING: but as it is at present continued in the formation of boats; therefore, how far whole-moulding may be used in the construction of boats, we shall endeavour to explain by introducing a boat, which might be whole-moulded from the stem to the stern-post, if part of the midship-bend was approved of for the shape of the transom; but as there can be no necessity that it should be so far whole-moulded, we shall omit it to the stern-post, but extend it quite forward to the stem.

The length, stem, and stern-post, being determined on in *Plate Ship*, fig. 1, the next thing is the station of the midship-frame, which is not of material consequence, only let it be before the middle of the boat. Then set off all the stations of the timbers afore and abaft the midship-bend.

The height in the midships being given, draw the sheer-line, or top of the gunwale, so that it may have an agreeable appearance. The line below it shews the breadth of the sheer-strake, and the ticked line above it shews the upper edge of the wash-board.

The next thing is the rising-line, which requires some experience to determine at once, so as to answer every purpose; for not only the form of the midship-bend, but likewise the design of the boat must be kept in mind, to know how far we may venture to lift the rising-line afore and abaft, without occasioning any hindrance to her stowage.

Having determined the height of the rising-line, dispose of the main height of breadth-line at the midship-bend, at such height as will best suit the intended form of the midship-bend, and continue it from thence forward and aft, parallel to the rising-line; for so far as the boat is to be whole-moulded, the main height-of-breadth and rising-line must be parallel to each other in the direction of the square timbers.

In the half-breadth plan, fig. 2, square down from the sheer-plan, fig. 1, when the height-of-breadth line crosses the fore part of the rabbet of the stem, and the aft part of the rabbet of the stern-post, or aft-side of the transom. But as this line rises above the transom abaft, observe where the top of the side crosses the aft part of the transom, and draw it parallel down from any of the stations of the timbers. Also square down the station of the midship-bend.

Set off from the middle-line, A B, fig. 2, the half-thickness of the stem, and from thence sweep an arch to the thickness

thickness of the board used for the bottom, the back of which arch will give the ending of the fore part of the main-half-breadth line. Then set off the half-breadth to the outside of the timber at the midship-bend, and draw *CD* parallel to *AB*. Determine the breadth of the transom at the top of the side, and set off the half-breadth on the line for the aft-side of the transom.

Thus we have three spots, one at the aft-side of the transom, one at the midship-bend, and one at the stem, through which draw an unlimited curve; observing to make it faint about half the length of the boat in midships, and to form the bow by part of a circle.

To form the Midship-bend.—Draw the horizontal line *AB* (*fig. 3.*), and erect a perpendicular in the middle; then take the half-breadth of the boat at the midship-bend, in *fig. 2.*, and set it off on each side the middle-line, and erect the perpendicular *CD*. Take the height from the line *AB*, *fig. 1.* (which is the upper edge of the rabbet of the keel) to the rising-line, and to the height-of-breadth line at the midship-bend; and set off above the line *AB* on the perpendicular *CD*, *fig. 2.*, and draw the lines marked *M B*, and “Rising.”

The distance from the rising-line to the height-of-breadth line is the radius of the circle intended for the midship-bend; which distance, set off from the point where the half-breadth line intersects the side perpendicular, *c*, on the height-of-breadth line, will give the centre for the sweep of the midship-bend; then sweep an arch from the intersection of the perpendicular *c* to the intersection of the rising-line.

From the middle-line set off the half-breadth of the keel on the line *AB*, and draw a straight line from the side of the keel to the back of the arch of the midship-bend: let the top of the side above the height-of-breadth line be perpendicular, complete the other side of the middle-line the same from perpendicular *D*.

To form the square Timbers of the Fore-Body.—Take the distance from the line *AB*, *fig. 1.* to the rising-line at timber *A B*, &c. as far forward as timber *I*, and set them off, and draw lines parallel to the line *AB*, *fig. 3.* from the middle-line towards the line *c*.

Then take the distance from the line *AB*, *fig. 1.* to the height-of-breadth line at each separate timber, and draw them as before in *fig. 3.* parallel to *AB*.

Then take the half-breadth of each timber, *A B*, &c. in *fig. 2.* and apply each separate distance from the middle-line in *fig. 3.* on the lines of their corresponding names for the height-of-breadth, and there make a spot.

Make a mould agreeable to the shape of the midship-bend, the lower part to agree with the rising-line of the midship-bend, and extend as far beyond the middle-line as is necessary.

Cross the height-of-breadth on the mould, and the middle-line, when it lies well with the midship-bend.

Take the distance from the line *CD*, *fig. 2.* to the main-breadth line at timber *A B*, &c. and set them off from the middle-line on the lower side of the mould, towards perpendicular *c*, which shews the narrowing of each timber more than the midship-bend.

From the height-of-breadth line in *fig. 1.* take the distance to the top of the sheer-strake at each of the above timbers, and set them off above the main-breadth, on the mould, which gives the heads of all the timbers in the fore-body.

The lower edge of the mould is supposed to be the height of the rising-line from the timbers.

Then apply the lower edge of the mould on each rising-

line, *fig. 3.* and move it till each letter on the lower edge of the mould agrees with the middle-line, and the main-breadth on the mould agrees with its corresponding height-of-breadth line. Then draw the form of the mould from the head of the timber to the middle-line, as ticked in *fig. 3.* and draw a straight line from the side of the keel, at the upper edge of the rabbet, to touch the outside of the curve formed by the mould, except where the rabbet of the keel and stem rises, as at *F, G, H, I*.

Set off the half-thickness of the keel from the middle-line, *fig. 3.* and take the height from the line *AB*, *fig. 1.* to the lower edge of the rabbet at each timber, and set it off from the line *AB*, *fig. 3.* on the line for the half-thickness of the keel or stem; then with compasses set to the thickness of the bottom plank, sweep an arch; from the upper side of which draw a straight line to the back of each curve of the mould, which will finish completely the heels of the timbers.

The same method must be observed in the after-body towards perpendicular *D*, *fig. 3.* applying the midship-bend mould in the same manner as directed in the fore-body, making use of the mould as far aft as timber *12*.

The after-square timber is *9*; therefore, to *9* may be finished the heels of the timbers, by drawing a straight line from the back of the whole-moulding curve to the back of the sweep at the rabbet of the keel.

In whole-moulding, but few moulds are necessary to be made to mould all the timbers. Thus the floor-mould is to be made to the midship-bend in *fig. 3.* a little above the diagonal line, *ab* or *ac*, which is to be the heads of the floors, and let the lower part of the mould correspond well with the rising of the midship-bend, as is shewn in *fig. 4.*

When the mould lies well, as in *fig. 3.* mark the middle-line on the lower edge of the mould, and the head of the floor on the outer edge. Make the inside of the mould to its proper scantling, and let the upper edge correspond well with the cutting-down of the inside of the midship-floors; which cutting-down is so marked in *fig. 1.*

Then in *fig. 2.* take the distance of each timber from the line *CD* to the main-half-breadth line, and set them off on the lower edge of the mould, from the middle-line of the midship-bend towards the outer end of the mould, which is the middle-line for each floor.

Now fix the lower edge of the mould in *fig. 3.* on each rising-height, in the same manner as the timbers were got in by whole-moulding; and when each mark on the mould is well with the middle-line, and on its proper rising, describe on the outer edge of the mould the heads of the floors, or the diagonal line *ab*, or *ac*.

Or, as in *fig. 4.* square the middle-lines of each timber, and then take the half-breadths of each floor from *fig. 3.* and set them off square from each middle-line in *fig. 4.* to intersect the edge of the mould.

The lower Futtock-Mould, fig. 5. is made to the rising-height of the midship-bend, and from thence to the top of the sheer; but need not be made so long at the heel as the floor-mould. The inside is made to the scantling, and the crossing of the middle-line and the floor-head, on the lower futtock-mould, is done in the same manner as on the floor-mould; or the best way is to lay the floor-mould on the lower futtock-mould, and cross it by the floor-mould. When the lower futtock-mould is laid in its place to the midship-bend in *fig. 3.* then mark the main-breadth on the mould, which is the main-breadth for all the timbers. Then take the distance in *fig. 1.* from the main-breadth line to the top of the sheer at each timber, and set it off on the mould, from the main-breadth

WHOLE-MOULDING.

breadth upward, which is the heads of all the timbers; and then the crossing of the lower futtock-mould is finished.

To cross the rising Square.—When the boat is whole-moulded, the floors and lower futtocks are generally moulded by the use of the rising-square; which is so called, because when the square is properly placed to mould any timber, one side of the square corresponds with the rising of that timber. When the timbers are moulded by the outside of the mould, and the heels by the rising-square, (which gives the upper edge of the rabbet of the keel, or bearding-line,) then there is a batton, called a cutting-down batton, with the heights of all the floors, from the upper edge of the rabbet of the keel to the cutting-down line; which gives the cutting-down or inside of all the floors.

To make the rising-square, let one side of the square be of sufficient breadth to receive the rising and the cutting-down, as may be seen by the square E.

When moulding the floors, or lower futtocks, the lower side of the mould is the rising of the timber; and consequently the edge of the square, which is to be applied to the under side of the mould, is also the same.

Then to mark or cross the square, take the distance from the rising-line in *fig. 1*: to the upper edge of the rabbet of the keel, or bearding-line, at each timber; and set them off from that edge of the square which is to be applied to the mould, on the other edge of the square, and close to the edge, drawing a margin to put the letters or figures under them. Then take the distance in *fig. 1*. from the rising-line to the cutting-down line, at the timbers, where the cutting-down is below the rising, and set them off from the edge of the square that is to be applied to the mould on the other edge of the square, but within the risings, as may be seen on the square. The other timbers, from 3 to B, where the cutting-down is above the rising, may be marked on the moulds.

From the edge of the square where the risings are placed, set off on the other edge of the square the half-thickness of the keel, which call the middle-line; and then the square is ready for moulding.

To mould the Floors.—The best way for moulding the floors for a whole-moulded boat, is to make two moulds, agreeable to the former directions, made and crossed both alike, but the sides reversed. Then lay one on the other, the same as in *fig. 4*, keeping the lower edges in a straight line, and mooring them till the corresponding middle-lines on the moulds agree. The moulds in *fig. 4*. are fixed at 9, but the middle-lines on the lower mould cannot be seen; therefore, before the moulds are put together, it is best to mark (in chalk) on the edges of the mould the middle-lines of the timber. When the moulds are placed, fix the middle-line, marked on the edge of the square, to the middle-line on the mould of the timber, and the other edge of the square will represent the side of the keel.

Then apply a straight batton to the rising of 9, on the edge of the square, and also to the outside of the floor-mould. This will give the moulding of the outside of the floors, except timber 9, which is somewhat hollow. Then square the cutting-down for 9, across to the edge of the square, and draw a straight line to touch the inside of the mould.

In the same manner mould the other arm of the floor, by canting the square. But the rising and cutting-down should be marked on both sides.

Before the moulds are moved, mark the heads and firmarks, if any, as a guide to fix the lower futtock when put in its place, if it should not run down to the side of the keel.

To mould the lower Futtocks.—The lower futtock-mould is *fig. 5*, which is made in the same manner as the floor-mould, but continued as high as the top of the sheer. The upper part being straight and perpendicular, and the mould made to the scantling, there is no difference between moulding one side of the floors and moulding the lower futtocks.

The same method of fixing the square for the moulding of the floors will serve to mould the lower futtocks, as on the square in the plate, where the middle-line on the square is put to the middle-line on the lower futtock-mould for G. A straight batton applied to the rising for G, on the square, and to the back of the lower futtock-mould, gives the moulding of the outside of the lower futtock; and the cutting-down for G on the square brought to the edge of the square, a straight batton from thence to the inside of the mould will also be the inside of the lower futtock.

Mark the firmark, or floor-head, in the same manner as the floors, in order to place the lower futtock to its proper height at the side of the floors, in case they should not be required to run down to the side of the keel.

Likewise mark the main-breadth, and the head for G, before the mould is moved.

That there is no difference between the floors and the lower futtocks in using the rising-square, may be seen more clearly in *fig. 4*, where the floor-mould is continued up to the top of the side, which makes the lower futtock-mould; so that the form of the lower futtock is seen, as well as the floor.

The two floor-moulds may be made to serve for all the floors, by putting the fore-body on one side of the mould, and the after-body on the other; but observe to cross one mould opposite to the other, so that when it is canted over, it shall then be proper to mould with.

Two rising-squares are sometimes used; one for the fore-body, and the other for the after-body; because the squares must be crossed alike on both sides, to mould the arms of the floors, and likewise to mould the lower futtock for both sides of the boat. Or, instead of this, the fore-body may be put on one side of the square, and the after-body on the other. When the square is wanted on the opposite side, chalk on the edge of the square the rising and the cutting-down for the timber to be moulded, and then cant the square.

Two lower futtock-moulds may also be made, or cross the fore-body on one side of the mould, and the after-body on the other. In order to mould a timber for that side of the ship where the firmarks are at the under side of the mould, chalk the firmarks for the timber wanted on the edge of the mould; or make two margins on the edge of the mould, reserving one for the fore-body, and the other for the after-body, and reversed on the opposite side.

The lower futtocks for boats generally run about half way between the floor-head and the side of the keel; but if it were a hoy, or small vessel that was whole-moulded, the lower futtocks might then be required to run to the side of the keel, or dead-wood; wherefore, it is proper to shew the moulding of them down to the side of the keel.

Various are the methods used by different artificers in moulding the lower futtocks; and it is evident that the method which has been practised most will appear the best.

Some will make no use of the square, but mark the heels of the lower futtocks on the mould, and provide a batton, marked the same as the square; the lower end of the batton being long enough to mould the outside of the foremost and aftermost timbers; and the upper end of the batton being long enough to mould the inside of the midship-timber.

Mark

Mark a firmark across the batton, supposed to represent the side of the square, which must always be fitted well to the lower edge of the mould; from which firmark, supposed to be the rising for all the timbers, set off close to the edge of the batton the heels of all the timbers in the fore-body, or the distance in *fig. 1.* from the rising-line to the upper edge of the rabbet of the keel, or bearding-line.

Then draw a margin for the cutting-down of the timbers, and take the distance in *fig. 1.* from the rising-line of each timber to the cutting-down, and set them off on the batton for the cutting-down, as much above or below the firmark on the batton as the cutting-down is above or below the rising at each timber.

On the other side of the batton may be put the after-body.

In some boats or vessels, where the rising and cutting-down are farther asunder at the midship-bend, then the batton will be as useful as the square; but instead of the middle-lines being marked on the lower futtock-mould, it will be better to mark the side of the keel, or where the keels of the lower futtocks are intended to be, for the better applying the batton.

If the heels of the lower futtocks do not run down to the side of the keel, it will alter the risings on the batton; the heels being marked on the mould short of the side of the keel.

The proper heels of the lower futtocks should be marked on the mould, though moulded by the square; for then the edge of the square might be put to the proper mark on the mould for the heels of the timbers.

The middle-lines marked on the lower futtock-mould in the *Plate*, were intended only to shew that the method of moulding the floors and lower futtocks were alike. The square is the best to mould the floors, because the middle-lines are the properest to be marked on the floor-mould.

What has been said may suffice to shew that whole-moulding may, in some measure, be used, and yet form a pleasing draught, much more so than that of the boat in *fig. 1.* if less stowage were sufficient to answer the purpose for which she is designed.

WHOLE-SOME SHIP, in the *Sea Language*, one that will try, hull, and ride well, without rolling or labouring in the sea. A long ship that draws much water may try, hull, and ride well; but if she draws little water, she may try and ride well, but never hull well; and a short ship that draws much water may hull well, but neither ride nor try well; and such is called an *unwholesome ship*.

WHORE. See **COURTESAN**, **HARLOT**, **CONCUBINE**, &c.

WHORL, in *Botany*. See **VERTICILLUS**.

WHORLBAT, or **HURLBAT**, a kind of gauntlet, or leathern strap, loaden with plumbets; used by the ancient Romans in their solemn games and exercises; and by them called *castus*.

WHORLED PLANTS. See **VERTICILLATÆ**.

WHORLES of *Flowers*, among *Herbalists*, are rows of lesser flowers, set at certain distances about the main stalk or spike, as in penny-royal, &c.

WHORTLE-BERRY, **BILBERRY**, or **Cranberry**, in *Botany*. See **VACCINIUM**.

The whortle-berry, with one flower upon each footstalk, oval-sawed leaves, which fall off in winter, and an angular stalk, called *black whorts*, or *bilberries*, grows very common upon large wild heaths, in many parts of England, but is

never cultivated in gardens, it being with great difficulty transplanted; nor will it thrive long when moved thither. The fruit is gathered by the poor inhabitants of those villages which are situated in the neighbourhood of their growth, and carried to the market-towns. These are by some eaten with cream or milk; they are also put into tarts, and much esteemed by people in the North, but they are seldom brought to London.

The shrub on which these grow rises about two feet high, having many stems, which are garnished with oblong leaves, shaped like those of the box-tree, but somewhat longer, and a little sawed on their edges. The flowers are shaped like those of the arbutus, or strawberry-tree, of a greenish-white colour, changing to a dark red toward the top. The fruit is about the size of large juniper-berries, and of a deep purple colour, having a flue upon it when untouched, like the blue plums, which is rubbed off with handling.

The whortle-berry with nodding bunches of flowers terminating the branches, and oval leaves which are entire, turned back and punctured on their under side, called *vitis idæa*, and *red whorts*, is an ever-green shrub, seldom rising above six or eight inches high, with leaves like those of the dwarf-box, which grows upon moors in several parts of the North, but is not capable of being easily transplanted: the berries are red, and have a more agreeable acid flavour than those of the first sort.

The whortle-berries with oval, entire, reflexed leaves, and naked, slender, creeping stalks, called *moss-berries*, *moor-berries*, and *cran-berries*, produce branches small as thread, and trailing upon the mossy bogs, which are garnished with leaves resembling those of thyme, with the upper surface of a shining green, and white underneath. The berries, which grow upon long slender foot-stalks, succeeding the flowers, are round, red, and spotted, of a sharp acid flavour, and much esteemed for tarts, or eaten with milk or cream. This is a native of bogs, and cannot be propagated upon dry land.

There are several other species of this genus, some of which are natives of Spain and Portugal, others of Germany and Hungary, and several of the northern parts of America; from whence those large fruits are brought to England which are used by the pastry-cooks of London, during the winter season, for tarts. But as all these sorts grow naturally in swamps and bogs, they are not easily transplanted into gardens in their native country, so as to thrive or produce fruit; therefore, there can be little hope of cultivating them to advantage. Miller.

WHORTLE-BERRY, *African*, a species of **ROYENA**.

WHORTLE-BERRY, *Bear's*. See **UVA URSI**.

WHUR, in *Falconry*, denotes the fluttering of partridges or pheasants as they rise.

WHY-EA-TEA, in *Geography*, a bay on the east coast of Owhyhee. N. lat. 19° 44'. E. long. 204° 54'.

WHYMEA BAY, a bay on the north coast of the island of Woahoo. N. lat. 21° 38'. E. long. 202° 51'.

WHYMEA Road, a road on the south-west coast of the island of Attowai. Captain Vancouver says, this bay is much confined in respect to safe anchorage.

WHYTE, **ROBERT**, in *Biography*, an excellent composer of church-services in the style of Palestrina, which, however, he could not imitate, as he was anterior to him, and a great master of harmony before the productions of this chief of the Roman school were published, or at least circulated, in other parts of Europe. Whyte was dead in 1581, when his Latin Full Anthems and Services were beautifully transcribed in a set of books, still preserved at Oxford;

Oxford; as we find by a distich at the end of a prayer, in five parts, upon a plain song: "Precamur Sancte Domine."

Maxima musarum nostrarum gloria Whyte
Tu peris; æternum sed tua musa manet.

Whyte preceded Tallis and Bird, and died before their fame was well established. His works seem never to have been printed; but in the library of Christ-church, Oxford, a sufficient number of them has been preserved in the Aldrich collection, to excite not only wonder, but indignation, at the little notice that has been taken of them by musical writers. Morley, indeed, has given him a place in the list of composers at the end of his Introduction, and ranks him, with Orlando di Lasso, among *excellent men*, who had ventured to begin a composition with a fourth and sixth; he likewise places him with Fairfax, Taverner, Shepherd, Mundy, Parsons, and Bird, "famous Englishmen who have been nothing inferior to the best composers on the continent." And no musician had then appeared who better deserved to be celebrated for knowledge of harmony, and clearness of style, than Robert Whyte, as is manifested in Burney's *Hist. of Mus.* vol. iii. by an anthem for five voices.

But besides this masterly composition, and a great number of others, to Latin words, which were scored from the Christ-church books, and which were probably produced at the latter end of Henry VIII.'s reign, or during the time of queen Mary, when the Romish religion was still in use, we are in possession of a small MS., which, by the writing and orthography, seems of the 16th century, entitled "Mr. Robert Whyte, his Bitts, of three Parte Songes, in Partition: with Ditties, 11; without Ditties, 16." These are short fugues or intonations in most of the eight ecclesiastical modes, in which the harmony is extremely pure, and the answer to each subject of fugue brought in with great science and regularity. Burney.

WHYTHORNE, THOMAS, gentleman, in *Musical History*, author of a book of songs, printed by John Daye, in 1571, under the following title: "Songes of three, fower, and five voyces, composed and made by Thomas Whythorne, gentleman, the which songes be of fundrie fortes, that is to say, some long, some short, some hard, some easie to be songe, and some between both; also some solemne, and some pleasaunt or mery: so that according to the skil of the fingers (not being musitians), and disposition or delite of the hearers, they may here find songes to their contentation and liking."

Our secular vocal music, during the first years of Elizabeth's reign, seems to have been much inferior to that of the church, if any judgment can be fairly formed of it from this book, published before the songs of Bird had appeared, and of which both the words and the music are alike truly barbarous. But we have, in our own time, music-books published in England every day without genius or science to recommend them. And it is not certain that Whythorne's songs were ever in much public favour. Now, if it should happen that one of these, by escaping the broom of Time, should reach posterity, and fall into the hands of some future antiquary, critic, or historian, who should condemn *all* the compositions of the present age by *one*, that had, perhaps, been never performed or heard of by contemporary judges and lovers of good music, the sentence would surely be very unjust.

WHYTT, ROBERT, F. R. S. in *Biography*, a distinguished physician, was born at Edinburgh in 1714, educated at St. Andrew's, and studied physic first at Edinburgh, and afterwards at London, Paris, and Leyden. He settled in his pro-

fession at Edinburgh, where he became a fellow, then president of the college of physicians, and in 1746 chairman of the institutions of medicine in the university. As a medical practitioner and teacher, and also as a writer, he acquired celebrity. The first of his publications was an "Essay on the Vital and other Involuntary Motions of Animals," 1751, in which he advances a theory different from that of Stahl, as he attributes these motions not to the soul, acting to a foreseen end, but to the power of stimulus. In 1755 he published "Physiological Essays, containing an Inquiry into the Causes which promote the Circulation of the Fluids in the very small Vessels of Animals; with Observations on the Sensibility and Irritability of the Parts of Man and other Animals." Here he supposes that the action of the heart is not sufficient to propel the blood through the minutest vessels, but that it is assisted by an oscillatory motion of the vessels themselves. Of this work, an enlarged edition appeared in 1761. His other works are, "An Essay on the Virtues of Lime-water in the Cure of the Stone," 1752; "Observations on the Nature, Cause, and Cure of those Disorders which are commonly called Nervous, Hypochondriac, and Hysteric," 1764; and some papers in the Edinburgh "Essays and Observations, Physical and Literary." A posthumous work appeared, entitled "Observations on the Dropsy of the Brain." Having long laboured under a complication of chronic complaints, he died in 1766. His son published an edition of all his works in 1768, 4to. under the inspection of sir John Pringle. Haller Bib. Anat. Gen. Biog.

WIA, in *Geography*, one of the small western islands of Scotland, a little to the south of Benbecula. N. lat. 57° 22'. W. long. 7° 11'.—Also, one of the small Western islands, near the east coast of Barray. N. lat. 56° 58'. W. long. 7° 22'.—Also, a small island near the west coast of Skye. N. lat. 57° 21'. W. long. 6° 27'.

WIAMPA, or WINITA, or *Sinpa*, a town of Africa, on the Gold Coast, in the district of Agonna.

WIANDOTS. See WYANDOTS.

WIAPOCO, or LITTLE WIA, one of the navigable mouths of the Oroonoko.

WIBALDUS, in *Biography*, a person of note in the 12th century, descended from a noble family in the bishopric of Liege, completed his studies at Liege, and became a teacher first at Vasso, and afterwards at Stablo. In 1130 he was elected abbot; and in 1136 he accompanied the emperor Lotharius on his expedition to Italy, by whom he was employed in several important departments, and fixed as abbot in the monastery of mount Cassino. But he quitted this monastery in the following year, and returned to Germany. In 1146 he became abbot of the monastery of Corvei on the Weser, in which he was confirmed by king Conrad, to whom he was no less an object of confidence than he had been to Lotharius. He was no less a favourite with Frederic I., who had sent him twice as ambassador to Constantinople; but on his return from his last mission thither, he terminated his life at Buleltia, in Paphlagonia, in consequence, as it is said, of poison, which had been given to him in the month of July, 1158. His Letters, mixed with some other works, one volume of which only remains, throw considerable light on the state of society at that time, and on the ecclesiastical history of Germany. Gen. Biog.

WIBLINGEN, in *Geography*, a town of Bavaria, with a Benedictine abbey, near the conflux of the Iler with the Danube; 3 miles S.S.W. of Ulm.

WIBORGIA, in *Botany*. See VIBORGIA.

WIBURG, in *Geography*. See VIBORG.

WIBY, a town of Sweden, in the province of Nericia; 18 miles S.W. of Orebro.

WIC, denotes a place on the sea-shore, or on the bank of a river. Though in the original Saxon, it more properly signifies a *street, village, or dwelling-place*; as also a *castle*. See WYKE.

We often meet with *wic* in the Saxon writers, as a termination of the name of a town which had a complete name without it: as, *Lunden-wic*, that is, London-town; which signifies no more than *London*. In the Saxon Annals, it is mentioned, that king Ethelbert made Melitus bishop of *Lunden-wic*.

So, Ipswich is written in some old charters, *will de Gippo*, and sometimes *villa de Gippo wico*; which is no variation, but the same thing; for *Gipps* is the complete name, and the *Gipp-wic* is Gipps-town.

WICCAKAW, in *Geography*, a town of the state of Georgia; 22 miles N.N.W. of Oakfuskee.

WICHRA, a river of Saxony, which rises three miles N. of Waldenburg, and runs into the Pleiss, 2 miles N. of Borna.

WICHTIS, a town of Sweden, in the province of Nyland; 27 miles N.N.W. of Helsingfors.

WICHRACH, a town of Switzerland, in the canton of Berne; 12 miles S.S.E. of Berne.

WICK, a royal borough, market-town, and the county-town of the shire of Caithness, Scotland, is situated at the entrance of the small river Wick, the estuary of which forms a good harbour, at the distance of 279 miles N. from Edinburgh. The town is small, and the streets narrow and confined; but there are several respectable buildings to ornament the place. The church is an old, dark, and ill-constructed edifice. A weekly market is held on Fridays, and is well supplied. The chief sources of commerce and industry are the fisheries, which are prosecuted with great attention and success. The town and borough-lands of Wick were anciently part of the earldom of Caithness: on the petition of George, then earl, a charter was granted by James VI. of Scotland, Sept. 24, 1589, erecting the town of Wick into a royal borough, under the superiority of that nobleman. In 1672 the whole earldom of Caithness was disposed of to John Campbell, afterwards created earl Breadalbane, by whose successors it was sold to the family of Sinclair, in whom the superiority is still vested. In 1716 the convention of royal boroughs fixed the sett or government of the borough of Wick. By this sett, the old magistrates nominate two persons, out of whom a provost and two baillies are to be chosen by the free burgeses: the provost and two baillies so elected have the right of choosing seven counsellors, a treasurer, and a dean of guild. Wick, in conjunction with the boroughs of Dingwall, Dornock, Kirkwall, and Tain, sends one member to parliament. The parish of Wick is twenty miles long and ten broad; and in the population return of the year 1811 is stated to contain 5080 inhabitants. Carlisle's Topographical Dictionary of Scotland, 4to. 2 vols. 1813. Gazetteer of Scotland, 1806. Beauties of Scotland, vol. v. Caithnessshire.

Wick, a river of Scotland, which runs into the Northern ocean, at Wick, in the county of Caithness.

WICKER, a twig of the osier shrub, single or wrought.

WICKER-Basket, in *Rural Economy*, any sort of basket which is made of wicker-work, or the plaited or twisted twigs of the willow, or other such kinds of young shoots. See BASKET.

A sort of wicker-basket or braid, too, is made use of

in grafting in field, orchard, or fruit grounds. It is observed in the Gloucestershire Report on Agriculture, that the grafts are secured immediately after the compost is put on, with "braids." These are open wicker-baskets in the form of an inverted cone, fitting the stock below the place to which the compost extends, and rising about two feet high, and expanding at the top to nearly the same diameter. This contrivance serves not only to guard the grafts in their early state, but also to keep the shoots to a proper compact form of growth. The practice chiefly prevails on the banks of the Severn, where the osier (*salix viminalis*) is grown in great abundance.

In hop-grounds likewise large wicker-baskets are employed for picking the hops into. See HOP.

And wicker-work of the basket kind is made use of for many other purposes of different sorts.

WICKER-Tree, a name given by the English to a tree common in China, and described by Kircher and others. It is, as it were, a rope twisted by nature, about an inch thick, and creeps along the earth often for above a hundred paces together, much embarrassing the way, but serving for cables of ships, seats, hurdles, beds, mats, and various other necessary uses. It endures no vermin, and is much valued for being cool and refreshing in the hot seasons.

WICKER-Work, in *Agriculture*, a sort of basket-work on a large scale, used for defending land from water of the sea or other kinds. It is observed by Mr. Loudon, in his work on "Country Residences," that in some very sandy shores, defences of the embankment kind may be made of wicker-work; and that three or four rows of paling may be made of different heights, and the intervals between them be filled with furze, brushwood, straw, or any other such materials. It is thought that these materials would retain the sand as the tide passed through among them; and that in a very short time a defence or fort of embankment would be formed of the shelving kind, which should then be planted with the upright sea lime-grass, in order to bind it. See EMBANKMENT, and WATER, *Sea, Defending Land from*. Also UPRIGHT *Sea Lyme-Grass*, and ELYMUS *Arenarius*.

WICKERAD, in *Geography*, a town of France, in the department of the Roer. It gave name to a lordship, surrounded by the duchy of Juliers; 3 miles N.E. of Erkelens.

WICKET, of the French *guichet*, a little door within a gate; or a hole in a door, through which to view what passes without.

WICKFORD, in *Geography*, a town of Rhode island, with a post-office; 10 miles N.W. of Newport.

WICKHAM, commonly called *Market-Wickham*, to distinguish it from two other places of the same name in the county, is a village and parish in the hundred of Wilford, and county of Suffolk, England. It has been a place of much greater consequence than it is at present, and had a weekly market and town-hall, where the quarter-sessions were held. The spiritual courts for the archdeaconry of Suffolk are still held here. The parish-church, being built on a hill, constitutes a land-mark for vessels sailing by the coast. From the tower, a spectator may see nearly fifty other churches. An aisle, or chapel, on the south side of the church, was built by Walter Fulburn, of this parish, who died, and was buried within its walls, in 1489. The rectories of Wickham, Pettistree, and Bing, all in the hundred of Wilford, were bequeathed in 1718 by Mr. John Pemberton for charitable uses. According to the population report of 1811, this parish contained 133 houses, and 906 inhabitants. It is 12½ miles N.E. of Ipswich, and

and 81 in the same direction from London. The market, which was formerly held on Saturdays, has long been discontinued.—*Beauties of England and Wales*, vol. xiv. Suffolk, by F. Shoberl.

WICKHAM *Breaux*, and WICKHAM *Streyth*, the names of two other parishes in Suffolk, England.

WICKLIFFISTS, or WICKLIFFITES, in *Ecclesiastical History*, a religious sect, who had their rise in England in the 14th century, and their name from their leader *John Wickliffe*.

Wickliffe, of whose opinions we give some account in his biographical article, (see WICKLIFF,) denied that bishops were of a different order from priests, and that by virtue of their office they had any power to do what priests have not; and that in the apostolic times the two orders subsisting in the church were those of priest and deacon. With regard to tithes, he observes, that we do not read in the Gospel where Christ paid tithes, or commanded any man so to do; and that if they were due by God's commandment, there should be every where in Christendom one manner of tithing; and that those things which are due to priests should be given freely, without exaction or constraining. In opposition to the papal claims of supremacy and dominion, he maintained that the grants of emperors may be refused; that St. Peter and his successors have no rights conferred upon them of civil or political dominion; that the persons of the clergy and the goods of the church are not exempted from the civil powers; and that bulls of absolution or excommunication are conditional and not absolute, and depend for their effects on the disposition and character of those to whom they pertain.

Wickliffe defines heresy to be error maintained against holy writ, and that in life and conversation, as well as in opinion. He ventured to affirm, that children who die without baptism may be saved; that this rite does not confer grace, but only signify that which was before given; and he denied that all sins are abolished by baptism. But in these and some other points, occurring in his various works, which were published at different times, he is not always perfectly consistent; but in all matters of principal importance he is uniform.

He left many followers in England and other countries, who were called Wickliffites and Lollards, and who held their opinions in private without making any public profession of them; though they were generally known by their disparaging the superstitious clergy, whose corruptions were so notorious, and their cruelty so enraged, that it was no wonder the people were much prejudiced against them. Wherever they could be found, they were terribly persecuted by the inquisitors, and other instruments of papal vengeance.—*Lewis's History*, &c. 8vo. passim. *Mosh. Eccl. Hist.* vol. iii. 8vo. *Burnet's Hist. Reform.* vol. i. p. 23.

WICKLOW, in *Geography*, a maritime county of Ireland, on the east coast, having the county of Dublin on the north, the Irish sea on the east, the counties of Kildare, Dublin, and Carlow, on the west, and that of Wexford on the south. Its extent from north to south is 32 Irish ($40\frac{1}{2}$ English) miles; from east to west, 26 Irish (33 English) miles; and the superficial contents are 311,600 acres, or 486 square miles, equal to 500,600 acres, or 780 square miles English. Mr. Radcliffe, according to the county map, states the superficial contents at 305,404 Irish acres. There are 58 parishes, which have 20 churches, mostly in the archbishopric of Dublin. Dr. Beaufort states the population at 58,000. "A great part of Wicklow is rendered unfit for habitation, and incapable of culture, by mountains intermixed with rocks and bogs. How-

ever, though the heart of the county be a cheerless waste, the hills on the east and west sides, and especially along the coast, are from six to eight miles in breadth, being many of them well wooded, and intermixed with profitable and smiling valleys, form a delightful and various scenery. They are crowded with gentlemen's seats, and are not without small towns and villages." This was Dr. Beaufort's account in 1792. In 1801, captain Frazer published a statistical account for the Dublin Society. This gentleman laments, that "the Wicklow farmers foul the land by repeated corn-crops, and seldom or never lay it down to graze with seeds." He deplores "the total neglect of the improvement of the breed of animals for stock and labour;" and under the head of ploughs he remarks, "the common plough in use in this district is the swing-plough; it is seldom, however, formed on any scientific principles, and is generally very clumsy, and ill-adapted for making clean or regular work." In 1812, however, when the Rev. Thomas Radcliffe published a Report of the Agriculture and Live-Stock of the County of Wicklow, a very great change had taken place. A few extracts from this interesting publication will furnish the reader with the most authentic information on the state of this county, and of what has been effected by the exertions of the Farming Society of Ireland, its own local Farming Society, and the encouragement as well as example of good landlords.

The climate of the county is, in general, mild; but on the eastern side, along the sea-coast, is peculiarly warm, and favourable to vegetation; inasmuch that there is almost a perpetual spring; and land of an apparently light quality is known to produce crops equal, if not superior, to those on the richest soils in other parts of Ireland. The crops commonly cultivated are, potatoes, wheat, barley, and oats. With respect to potatoes, the valuable system of drilling is almost universally adopted. The quantity of wheat is inconsiderable: it is generally taken after the potatoe-crop, sometimes after another white crop, or upon the lea; but the periodical fallow for wheat is fortunately unheard of. The barley-crop is taken after potatoes or turnips, and, like the wheat, is sown under the plough. The oat-crop, by the common practice, is taken upon the lea; but if upon stubble-ground, it is sown under the plough. The crops are not exceeded in quantity or quality in any part of Ireland. Green crops are not in much use among the tenantry. The manure in this county, besides dung, consists of brown, blue, and white marl, lime and lime-stone gravel. In the greatest part of this county, the implements of the best construction are in very general use; such as the Scotch plough, as recommended and supplied by the Farming Society, the Scotch harrow, the Scotch cart, drill-machines, and even the threshing-machine. Most of the improved breeds of cattle have been introduced into this county; but Wicklow cannot be considered as a breeding county. The dairies are numerous; but, on a contracted scale, averaging from eight to sixteen cows, and almost uniformly engaged in the feeding of veal for the Dublin market. In the northern part of the county, much of the milk is consumed in fattening early lamb. The county of Wicklow, though not to be classed as a breeding county with respect to cattle, is very extensively so with respect to sheep, its vast tracts of mountain supplying a wholesome, though not an exuberant, pasture to that animal. The breed of this county is the mountain kind; and the number of breeding ewes may be stated at 20,000. The South Down are the favourites with the gentlemen; and many flocks of the native mountain have been crossed with South Down. The Merino sheep have also been successfully introduced. The

cotton manufacture is carried on with spirit at Stratford-upon-Slaney. The woollen manufacture is chiefly limited to the flannel-trade. This, however, is carried on largely, and is a source of fair profit and industrious occupation. It prevails on the property of earl Fitzwilliam, and the Flannel-hall at Rathdrum was built at his lordship's expence. The average annual sale is about 5000 pieces of 120 yards each.

The romantic beauties of this county have been often described. The vicinity to Dublin makes them easily accessible, and few travellers omit to visit them. The antiquities of Glendalough have been noticed in the proper place, under that name. The mineralogy of Wicklow has been noticed in Dr. Fetton's valuable Notes on the Mineralogy of the Neighbourhood of Dublin; and on this head Mr. Griffith's Report on the Mountain District of Wicklow should also be consulted. This uncultivated district has many peculiarities, which consist chiefly in the facility of access by means of roads; the vicinity of highly improved lands and industrious inhabitants; the frequent occurrence of beds of lime-stone, gravel, and marl; the best manure for the amelioration of mountain soils; and the uncommon mildness of the climate. These uncultivated lands occupy about 200,000 Irish acres, of which about 60,000 consist of black bog; the remainder is moory soil, generally covered by coarse sedgey grass, or grass intermixed with heath. In this district, many rivers have their sources. The Liffey, with its tributary streams, takes a circular course through the county of Kildare, and falls into the bay of Dublin; the Slaney runs southward to the county of Wicklow; the Fartrey disembogues itself at Wicklow; and the Ovoca at Arklow. (For an account of the Cronbane mines, see CRONEBANE.) At Croghan Kinshela, in the southern part of the county, a quantity of native gold has been extracted by washing from the alluvial soil, of which an account, by Messrs. Mills and Weaver, may be found in the Transactions of the Dublin Society. Near 600 ounces of gold, worth above 2000*l.*, were extracted; but the vein could not be discovered, and the search for it was given up. Oxyd of tin was found in the same stream. The county of Wicklow has no large town, and has only the two members for the county to represent it in parliament.—Frazer's Survey. Beaufort's Memoir. Radcliffe's Report. Griffith's Report, &c.

WICKLOW, the assize-town of the preceding county, which is also a post-town. It is pleasantly situated on a small harbour, and near a beautiful strand abounding in fine pebbles, which is called the Murrough. The ale of Wicklow has been long celebrated in Dublin. It is 24 miles S.S.E. from Dublin.

WICKWA, a small lake of Canada, at the eastern extremity of Lake St. John.

WICKWAR, anciently WICKEN, a market-town in the hundred of Grombold's Ash, in the county of Gloucester, England, is situated 19 miles S.W. from Gloucester, and 108 miles W. from London, and consists of one long street. The town is incorporated and governed by a mayor and twelve aldermen. It has a weekly market on Monday, and two yearly fairs. In it two courts are held; one for the borough, and another for the tything, or foreign, which have separate constables. The clothing manufacture, which once flourished here, has long been on the decline; but the lower classes are still employed in spinning for the clothiers of other places. Wickwar contains a well-endowed free grammar-school, which was founded in 1684. The church, a handsome building on an eminence, consists of a nave and north aisle. The rectory is valued in the king's books

at 18*l.* The resident population in 1801 was 764; in 1811 it had increased to 805.—Hist. of the County of Gloucester, by the Rev. Thomas Rudge, B.D. Gloucester, 1803, 2 vols. 8vo.

WICLIFF, DE WYCLIF, WICLEF, or WICKLIFFE, JOHN, in *Biography*, the earliest reformer of religion from Popery, was born about the year 1324 in Yorkshire, near the river Tees, in a parish whence he takes his name. He was educated at Oxford, first as a commoner of Queen's college, and then at Merton college, peculiarly celebrated at that period for its learned members. His industry and talents soon raised him to distinction; and he is said to have committed to memory the most abstruse parts of Aristotle, and to have excelled in his acquaintance with the subtleties of the school divinity. He was also eminently skilled in civil and canon law, and in the law of the land. But the study which led to his future fame was that of the Scriptures; to which he added a diligent perusal of the Latin fathers, and of the writings of the English divines, Robert Groshead and Richard Fitz-Ralph. In his treatise "Of the Last Age of the Church," at the early period of the year 1356, he remonstrated against some Popish corruptions; and in 1360 he was active in opposing the encroachments of the Mendicant Friars, who interfered with the jurisdiction and statutes of the university, and took all opportunities of enticing the students from the colleges into their convents. In the following year, such was the credit he had acquired by his conduct and writings, he was appointed master of Baliol college, and was presented to a living in Lincolnshire. At this time he was held in such esteem by archbishop Simon Islip, that in 1365 he constituted him warden of Canterbury college, which he had just founded; but on occasion of a dispute between the regular and secular priests, Wickliffe and the three secular fellows were rejected; and on an appeal to Rome, the sentence against Wickliffe was confirmed in 1370. His reputation in the university was not at all diminished by his exclusion. In 1372 he took the degree of D.D., and read lectures, which gained him such applause, that whatever he said was regarded as an oracle. The impostures of the monks were the objects to which his first attacks were particularly directed; and the circumstances of the times favoured his design. The court of Rome was now enforcing by menaces its demands on king Edward III. of the homage and tribute to the see of Rome, which had been ingloriously stipulated by king John; and the parliament had determined to support the king in his refusal. A monk appeared as an advocate on behalf of the claims of Rome; and Wickliffe's reply caused him to be favourably regarded at court, and procured for him the patronage of the king's son, John of Gaunt, duke of Lancaſter. In 1374 Wickliffe was joined in an embassy to Bruges, the object of which was to confer with the papal nuncios concerning the liberties of the English church, on which the usurpations of Rome had made unwarrantable encroachments. In the same year the king presented him to the valuable rectory of Lutterworth, in Leicestershire; and in the following year he was installed in a prebend of the collegiate church of Westbury, in Gloucestershire. Wickliffe, by his foreign mission, had an opportunity of acquainting himself with the corruption and tyranny of the court of Rome; and both his lectures and conversations were amplified with invectives against the pope. Whilst he defended the authority of the crown and the privileges of the nobles against all ecclesiastical encroachments, he censured vice and corruption in all ranks of society. This conduct, though it raised his reputation among the people, excited a host of enemies, who selected from his writings nineteen articles, which they deemed heretical, and which,

WICKLIFF.

as such, they transmitted to Gregory XI. In 1377 this pontiff returned three bulls addressed to the archbishop of Canterbury and the bishop of London, ordering the seizure and imprisonment of Wickliffe; or, if this measure failed, his citation to the court of Rome; and also a requisition to the king and government to assist in extirpating the errors which he had propagated. Edward died before the bulls arrived; and the duke of Lancaster, uncle to the young king, had great influence in the administration. When Wickliffe, therefore, was cited to appear at St. Paul's church before the two prelates, possessing plenitude of power, he thought it necessary to secure himself by the protection of that powerful patron. On the appointed day he appeared at St. Paul's, in the midst of a vast concourse of people, and accompanied by the duke of Lancaster, and lord Henry Percy, earl-marshal. The bishop of London was very in signant, and angry words passed between him and the two lords; so that the whole assembly was tumultuous, and nothing was done. Wickliffe afterwards appeared before the two prelates in Lambeth palace, and delivered an explanation of the articles objected against him. The Londoners, who were apprehensive that he might be severely treated, flocked in crowds to the palace; and a messenger from the queen forbade the delegates to proceed to a definitive sentence. Gregory soon after died, and his commission expiring with him, Wickliffe escaped, but not without a severe illness, which was the consequence of his anxiety and fatigue. His spirits, however, were unbroken, and he was firm in maintaining opinions which the friars, by all the efforts of intimidation, urged him to renounce.

Upon his recovery, he presented to the parliament, in 1379, a paper against the tyranny and usurpations of Rome; and he also drew up some free remarks on the papal supremacy and infallibility. But his most effectual attack on the corruption of religion was his translation of the Bible into English. This occupied many of the last years of his life, and remains a valuable relic of the age in which it was performed, and a permanent memorial of the talents and industry of the person by whom it was accomplished. (See *English BIBLES*.) By way of preparation for his Bible, he published a treatise "Of the Truth of the Scripture," in which, as well as in a prologue or preface to his translation, he held, long before any of our other reformers or advocates for the sufficiency of Scripture, that this is the law of Christ, and the faith of the church; that all truth is contained in it; and that every disputation which has not its origin thence is profane. "The truth of the faith," says he, "shines the more by how much the more it is known—nor are those heretics to be heard who fancy that seculars ought not to know the law of God, but that it is sufficient for them to know what priests and prelates tell them by word of mouth; for the Scripture is the faith of the church, and the more it is known in an orthodox sense the better; therefore, as secular men ought to know the faith, so it is to be taught men in whatsoever language is best known to them. Besides, since the truth of the faith is clearer and more exact in the Scripture than the priests know how to express it—it seems useful that the faithful should themselves search out and discover the sense of the faith, by having the Scriptures in a language which they understand.—The laws which the prelates make are not to be received as matters of faith; nor are we to believe their words or discourses any farther or otherwise than they are founded on the Scripture;"—with much more to the same purpose, and in the same admirable strain. In this preface, and several other publications and treatises still in manuscript, he reflected severely on the corruptions of the clergy, condemned

the worship of saints and images, the doctrine of indulgences, pilgrimages to particular shrines, and confession; and also denied the corporal presence of Christ in the sacrament, inveighed against the wanton exercise of the papal power, and opposed the making of the belief of the pope's being head of the church an article of faith and salvation, censured the celibacy of the clergy, forced vows of chastity, exposed various errors and irregularities in the hierarchy and discipline of the church, and earnestly exhorted all people to the study of the Scriptures.

In his lectures of 1381, he attacked the Popish doctrine of transubstantiation, concerning which he laid down this fundamental proposition; viz. that the substance of bread and wine still remained in the sacramental elements after their consecration, and that the host is only typically to be regarded as the body of Christ; and he deduced from it sixteen conclusions. This attack alarmed the church, which regarded transubstantiation as the most sacred tenet of the Romish religion, and the chancellor of Oxford pronounced a condemnation of these conclusions. Wickliffe appealed from this sentence to the king; but he found himself deserted by his protector, the duke of Lancaster, who had no further occasion for his services, or who could not avail himself for any political purpose of his theological discussions. Thus circumstanced, he found himself in danger; his resolution failed him, and he humbled himself by making a confession at Oxford, before the archbishop and six bishops, with other clergy, who had already condemned some of his tenets as erroneous and heretical. In this confession, he admitted the real presence of Christ's body in the sacrament, with some explanations and reasons which were not satisfactory to his persecutors. It has been said that he made a public recantation of the opinions with which he was charged; but of this no sufficient evidence appears. The next step in their proceedings against him was a royal letter, procured by the archbishop, addressed to the chancellor and proctors, and directing them to expel from the university and town of Oxford all who should harbour Wickliffe or his followers, or hold any communication with them. These proceedings obliged him to withdraw, and to retire to his rectory at Lutterworth, where he continued to preach reformation in religion, and finished his translation of the Scriptures. Some have said that king Richard banished him out of England; but if that were the case, it was only a temporary exile, and he returned in safety to Lutterworth. In 1383 he had a paralytic stroke, which furnished him with an apology for not appearing to a citation of pope Urban VI.; and this was succeeded by a second attack, which terminated his life on the last day of December 1384. His remains, however, did not escape the vengeance of his enemies many years after his death; for the council of Constance in 1415, not content with condemning many propositions in his works, and declaring that he died an obstinate heretic, with impotent malignity ordered his bones to be dug up and thrown upon a dunghill. This sentence was executed in 1428, in consequence of a mandate from the pope, by Flemming, bishop of Lincoln, who caused his remains to be disinterred and burnt, and the ashes to be thrown into a brook. "Thus," says Fuller, the church historian, in a figurative strain justified by fact, "this brook hath conveyed his ashes into Avon, Avon into Severn, Severn into the narrow seas, they into the main ocean; and thus the ashes of Wickliffe are the emblem of his doctrine, which now is dispersed all the world over." His doctrine not only survived these impotent attempts to extinguish it, but was perpetuated and diffused by his followers, who were called Lollards; and "this germ of reformation," as one of his biographers

biographers says, "broke forth into complete expansion, when the season for that great change was fully come." Of his general character, it will be sufficient to say, "that he was confessedly learned for his age, and was an acute reasoner. In short, notwithstanding certain errors and imperfections, he may be regarded as a person of extraordinary merit and qualifications, who is entitled to honourable remembrance from every foe to ecclesiastical tyranny and imposture;" and we may add that he advanced principles which have not yet produced their full effect.

The number of tracts he wrote and published, both in Latin and English, is very considerable. From two large volumes of his works, entitled "Aletheia, i. e. Truth," and a third under the title of "Triologus," John Hufs is said to have derived most of his doctrines. We have a full and complete "History of the Life and Sufferings, and various Writings of Wickliffe," both printed and MS., published in 8vo., at London, in the year 1720, by Mr. John Lewis; who also published, in 1731, "Wickliffe's English Translation of the New Testament from the Latin Version, called the Vulgate." This translation is enriched with a learned preface by the editor, in which he enlarges upon the life, actions, and sufferings of this eminent reformer. Biog. Brit. Mosh. Eccl. Hist. Neal's Hist. of the Puritans. Gen. Biog. For an account of his distinguishing tenets, and those of his followers, see WICKLIFFISTS and LOLLARDS.

WICOMICO, in *Geography*, a river which rises in the state of Delaware, enters the state of Maryland, and passes into Fishing bay, on the east side of the Chesapeake, N. lat. 38° 16'. W. long. 75° 57'.

WICOMOCO, a river of Virginia, which runs into the Chesapeake, N. lat. 37° 55'. W. long. 76° 25'.

WICQUEFORT, ABRAHAM, in *Biography*, was born at Amsterdam in 1598, and having left his own country for France at an early age, he was nominated resident for the elector of Brandenburg at the French court, and held the office for thirty-two years. But being suspected by cardinal Mazarin of communicating secrets to his correspondents in Holland with regard to the amours of Lewis XIV., he was ordered, in 1658, to leave the kingdom; but in the mean time he was arrested, and confined in the Bastille. At length, in 1659, he was released and dismissed. However, in three months the cardinal recalled him, and settled on him a pension. On occasion of the war between France and Holland in 1672, he returned to his own country, and was protected by John de Witt, who employed him in writing a history of Holland to his own time. In 1676 he was arrested and condemned to perpetual imprisonment, under an accusation of carrying on a secret correspondence with the enemies of the state; and after having been confined for three years, he made his escape by the contrivance of one of his daughters. He then sought refuge at the court of Zell, from which he returned to Holland in 1681, where he lived without molestation, but without recovering the places of which he had been deprived. In the following year, 1682, he died. The work on account of which Wicquefort is best known, is entitled "L'Ambassadeur et ses Fonctions," first printed at the Hague in 2 vols. 4to. 1681, and often reprinted. He holds in high estimation the privileges of the order to which he belonged, as we may infer from his censure of Cromwell's spirited act of justice in executing the brother of the Portuguese ambassador for a murder: nevertheless he inculcates sound morality with regard to the conduct of diplomatists in the countries to which they are sent. His other works are, "Memoires touchant les Ambassadeurs et les Ministres;" one volume of

his "History of the Dutch Republic," which appeared in French at the Hague in 1719, fol.; and translations into French of the accounts of different embassies, and also of voyages and travels. Moreri. Gen. Biog.

WICRANGLE, in *Ornithology*, an English name for the matticefs, or greater butcher-bird, the *lanius cinereus major* of authors.

WICRANTUM, in *Natural History*, a name given by the people of the East Indies to certain fossil bodies, of the nature of the pyrites, of the size of peas, and formed into variously angular figures.

They look black and glossy, and much of the nature of blende, or mock-lead; but when put into the fire, they shew us by their smell that they contain sulphur. They are found in the diamond-mines.

The natives first powder them; and then mixing them with the juices of certain plants, they dry them, and then calcine them again. These processes they repeat at least sixty times; but the first calcinations are made with a mixture of divers urines, as that of the horse, the camel, the cow, and the like.

After this tedious preparation, they are given in coughs and colds, and are said to be a remedy even in consumptions.

WICZENIECZ, in *Geography*, a town of Poland, in Podolia; 6 miles N.W. of Kamniec.

WIDAWA, a town of the duchy of Warsaw; 22 miles S.W. of Siradia.

WIDDAU, a river of Germany, which joins the Rodau at Rotenburg, in the county of Verden.

WIDDY, in *Agriculture*. See WITHY.

WIDE, is used in some places to denote a small vale, and also a wide piece of water, or pond.

WIDE-EARED, in the *Manege*, is applied to a horse, when the root, or lower part of his ear is placed too low, and the ear itself is too large. The French use the term *oreillard* for such a horse.

WIDE Bay, in *Geography*, a bay on the east coast of New Holland, between Double Island Point and Indian Head.

WIDE Mouth Bay, a bay of England, on the N.W. coast of Cornwall. N. lat. 50° 46'. W. long. 5° 19'.

WIDEKINDI, or WIDICHINDI, JOHN, in *Biography*, a Swedish historian, was born in the province of Westmanland, about the year 1620, and studied at Upsal, where he delivered an oration in 1654, on occasion of queen Christina's accession to the throne; and by her recommendation he was appointed historiographer of the kingdom. In 1676 he proposed printing his "History of Gustavus Adolphus," and measures were taken for this purpose; but he died at Stockholm in 1678, before the work was executed. The first part of this history was published in 1691, fol.; but as it much offended both the Danes and Russians, it was suppressed by the king's command. It is not known whether he completed the work in MS.; but the part published is written in a dull, heavy style, and it has been carelessly printed. The author, however, was a man of learning, well acquainted with history, and reckoned a good Latin poet. He possessed an excellent library, and was much respected by king Charles Gustavus, who called him his philosopher. The most important of his works, a catalogue of which is given in "Schefferi Svecia Litterata," is the "History of the Russian War," written both in Latin and Swedish, 1672, 4to. Gen. Biog.

WIDERDRIESS, in *Geography*, a town of the duchy of Stiria; 2 miles S. of Windisch Gratz.

WIDJITZE, a town of Bohemia, in the circle of Czaflau; 8 miles W. of Czaflau.

WIDMINNEN, a town of Prussia; 14 miles N.W. of Lick.

WIDOW, VIDUA, a woman that has lost her husband.

Some also use the term *widower*, for a man who has lost his wife. Marriage with a widow is a kind of bigamy in the eye of the canon law.

The widow of a freeman of London may use her husband's trade as long as she continues a widow.

Mr. Kerseboom has given us a table, shewing how long four hundred and thirty-two widows lived, and finds, that at a medium, each lived fourteen years. Phil. Transf. N^o 468, sect. 3.

It appears that, in Germany, the number of widows dying annually is four times the number of widowers: thus, in Dresden alone, the number of widows who died in four years was 584; the number of widowers 149: *i. e.* 4 to 1. At Wittenberg, during 11 years, 98 widowers died, and 376 widows. At Gotha, during 20 years, 210 widowers died, and 760 widows. And as widows are certainly, one with another, several years younger than widowers, it may be concluded that the number of the former in life together could not be less than five times the latter.

Thus also, in 1770, the number of widows in life, derived from the whole body of professors and ministers in Scotland, was 380; but the number of widowers among them has, one year with another, been scarcely 90; *i. e.* not so much as a quarter of the number of widows. Price's Observ. on Rev. Paym. eff. 4.

These facts cannot be accounted for without admitting the greater mortality of males. See MARRIAGE, and MORTALITY.

There have been many schemes established for providing annuities for widows, for an account of several of which, see Price's Observ. &c. chap. ii. sect. 1, 2, 3.

Among the ancient Greeks, widows had the care of the eternal fire of Vesta committed to them; which charge among the Romans could be performed by virgins only, who from their office were called vestals. See VESTAL.

WIDOW of the King, was she, who, after her husband's death, being the king's tenant in capite, was driven to recover her dower by the writ *De dote assignanda*; and could not marry again without the king's consent.

WIDOW *Beneb*, in the county of Suffex, is that share which a widow is allowed of her husband's estate, besides her jointure.

WIDOW'S Chamber, a name given in London to the apparel and furniture of the bed-chamber of the widow of a freeman, to which she is entitled.

WIDOW-Wail, in Botany. See CNEORUM.

WIDURIS, in *Natural History*, the name of a stone found in Java, Malabar, and some other places, and described by Rumphius. Some species of this are all over of a fine white; others are of a dusky colour, with streaks of white; the simply white ones are semi-pellucid, and look very like the white of an egg. Some also have called this the *hyalops*, or *achates vitrea perspicuitatis*.

WIECK. See WEEK.

WIED, in *Geography*, a county of Germany, situated to the north of Treves, in the year 1560, divided into two parts: the Lower County, or New Wied, or Wied New Wied; and the Upper County, or Wied Runkel. Both had seats in the college of Westphalia counts.

WIED, *New*. See NEUWIED.

WIED, or *Old Wied*, a town of Germany, in the county of New Wied; 9 miles N. of Coblentz.

WIEDENBRUCK, a town of Westphalia, in the bishopric of Osnabruck; 32 miles S.S.E. of Osnabruck. N. lat. 51° 45'. E. long. 8° 18'.

WIEDERAU, a town of Saxony; 5 miles N. of Liebenwerda.

WIEDERSBERG, a town of Saxony, in the Vogtland; 8 miles W.S.W. of Oelsnitz.

WIEDERSPACH, a town of Germany, in the margrave of Anspach; 6 miles W. of Anspach.

WIEGANDSTHAL, or WIEGENTHAL, a town of Upper Lusatia; 11 miles S. of Lauban.

WIEHE, a town of Thuringia; 26 miles N.N.E. of Erfurt. N. lat. 51° 18'. E. long. 11° 35'.

WIELAND, CHRISTOPHER MARTIN, in *Biography*, was the son of a Protestant clergyman at Biberach, in Swabia, where he was born in September 1733. Educated by his father, he began at the early age of thirteen to distinguish himself by his Latin and German poems; and he pursued his education at Magdeburg and at Erfurt. Upon his return home he became affectionately attached to Sophia de Guterman, afterwards known by her works under the name of Mad. de la Roche. In the year 1750 he studied jurisprudence at Tubingen; but his time was chiefly devoted to the writing of verses, so that in 1752 he published a didactic poem in six cantos, entitled "The Nature of Things;" "Ante-Ovid, or the Art of Love;" and "Moral Letters and Tales." He also began an epic poem, on the subject of Arminius, the first five cantos of which he sent to the famous Swiss poet Bodmer; and he was thus led to visit Switzerland, and to cultivate a friendship with this celebrated poet, and to reside for some time in his house at Zurich. In this retired and tranquil situation, he applied with great diligence to the study of the belles lettres, and acquainted himself with the principal modern languages, such as English, French, and Italian, to which he afterwards added the Spanish and Portuguese. He also read Plato with great attention, and wrote several works, among which were the "Trial of Abraham," and "Letters of the Dead." After a residence of seven or eight years in Switzerland, he quitted this country, having formed his taste on the models of Euripides, Xenophon, and Shaftsbury, whose writings he had diligently studied; and in 1758 he published his "Arafpes and Panthea," a work which manifests the ascendancy which judgment and moral sentiment had acquired over his imagination. Upon his return in 1760 to his native city, he was appointed a director of the chancery, which office he held till the year 1769, reserving, however, some leisure moments for the composition of his philosophical romance, entitled "Agathon," and his beautiful didactic poem "Musarion." About this time he became intimately acquainted with count Stadion, a nobleman who lived with splendour near Biberach, who had cultivated a taste for literature, and who possessed an excellent library. He afterwards received from the elector of Mentz an invitation to be professor of philosophy and the belles lettres at Erfurt, and during his residence in this place he became acquainted with Anna Amelia, duchess dowager of Weimar, a patroness of polite literature, and in 1772 she appointed him tutor to the two princes, Charles Augustus and his brother Constantine, of whom she was guardian. In this situation he occupied himself in preparing a variety of works, both in prose and verse, which have done honour to German literature. He was at this time aulic counsellor to the duke of Saxe Weimar, with a pension, and a counsellor of government to the elector of Mentz. Wieland married his favourite daughter Charlotte to a bookseller at Zurich, who was a son of the celebrated poet Solomon Gessner. In 1797 he visited

visited his children at Zurich, and resided with his family in a romantic situation on the border of the lake, where he was visited by the most eminent literati of Switzerland. Conceiving a fond attachment to a rural retreat, he sold his house at Weimar, and purchased a small estate in the neighbourhood, where he fixed his abode. Although his fortune was small, his disposition was liberal; and he assisted many distressed young poets and authors for their contributions to the German Mercury, which he commenced in the year 1783. To the ex-monk Reinhold, who had escaped from Vienna, he was a generous patron, and gave to him one of his daughters in marriage. This monk was afterwards professor of philosophy at Kiel. He also supported another monk, who had fled to him from a Cistercian monastery in Swabia, during his residence at Jena, where he studied philosophy. Wieland had married in 1765 a person of good family at Augsburg, of whom he expresses himself in the highest terms of respect and affection, and by whom he had thirteen children; "found," he says, "in body and mind; with their mother, they form the happiness of my life." In 1807 this venerable poet was elected a member of the floral order at Nuremberg; and in 1808, Buonaparte sent him the cross of the legion of honour. After the battle of Jena, he was protected by a special order of that conqueror. He died in January 1813, in his 80th year. For the delineation of his talents and character by Kuttner and others, and an account of his works, which were very numerous, we must refer to his article in the General Biography, observing that his original works have been published in thirty-six large 4to. volumes, and six supplementary volumes. Leipzig, 1794—1802.

WIELAS, in *Geography*, a town on the east coast of the island of Gilolo. N. lat. $1^{\circ} 9'$. E. long. $128^{\circ} 30'$.

WIELCZYNY, a town of Lithuania, in the palatinate of Novogrodek; 40 miles S.E. of Slonim.

WIELDEMAN. See **WILDEMAN**.

WIELEN, a town of the duchy of Warsaw; 46 miles N.W. of Posen.

WIELICHOW, a town of the duchy of Warsaw; 25 miles S.S.W. of Posen.

WIELICZA, a town of Austrian Poland, celebrated for its salt-mines, which produce a great revenue to the emperor, to whose lot it fell in the year 1773. The inhabitants reside chiefly in the mines, and the church is underground; 8 miles S. of Cracow. These salt-mines, with the territory belonging to them, were assigned to the emperor of Austria by the treaty at Vienna in 1815.

WIELONA, a town of Samogitia; 20 miles S. of Rosienne.

WIELUN, a town of Poland, in the palatinate of Siradia; 16 miles S. of Siradia.

WIEN, a river of Austria, which runs into the Danube at Vienna.

WIENNERHORBEG, a town of Austria; 12 miles W. of Brugg.

WIENNERWALD, or *The Forest of Vienna*, the south part of the arch-duchy of Austria, bordering on Hungary.

WIEPERZ, or **WIPNZ**, a river of Poland, which runs into the Vistula, near Stericzka, in the palatinate of Sandomirz.

WIEN, JOHN, in *Biography*, a physician, was born in 1515, at Grave on the Meuse; and being domesticated with the famous Cornelius Agrippa, adopted his opinions with regard to the occult sciences. After having studied at Paris and Orleans, he took the degree of M.D. about the year 1534. In the course of his travels, he visited the court

of the duke of Cleves, and was appointed his physician. He died at Tecklenburg, in Westphalia, in 1586. He was a man of considerable learning; and though participating in a great degree the credulity of the age, he incurred the enmity of the monks by ascribing to deception and imposture the forcery, witchcraft, and magical practices, which they supported, to the operation of natural causes. The turn of his mind is discernible in his book "*De Dæmonum Prestigiis et Incantationibus*." In his treatise of medical observations he has given an account of the putrid fore throat, under the name of "*Angina pestilentialis*." Among his other writings are enumerated "*De Iræ Morbo, et ejus Curatione Philosophica, Medica, et Philosophica*;" "*Tractatus de Commentitiis Jejuniiis*;" "*De Tuffi Epidemica, Anno 1580*;" "*De Varenis, Morbo endemio Westphalorum*." Haller. Eloy.

WIERINGEN, in *Geography*. See **VIERINGEN**.

WIERNITZ, a town of Austria; 8 miles N. of Korn-Neuburg.

WIESE, a town of Silesia, in the principality of Grotkau; 2 miles N.E. of Weydenau.

WIESEN, a river of Germany, which rises in the Black Forest, and runs into the Rhine a little below Bâle.

WIESENBACHE, a river of Saxony, which runs into the Weiffnitz, 4 miles N. of Dippoldiswalda.

WIESENBRUN, a town of the county of Castell; 14 miles E. of Wurzburg.

WIESENBURG, a citadel of Saxony, in the circle of Erzberg; 5 miles S. of Zwickau.—Also, a town of Saxony; 15 miles N.N.W. of Wittenberg.

WIESENFELD, a town of the duchy of Wurzburg; 5 miles S.S.E. of Gemunden.

WIESENSTEIG, a lordship of Bavaria, situated between the territories of Ulm and Wurtemberg, about eight miles long, and nearly as much in breadth. It descended from the dukes of Teck to the counts of Helfenstein, and gave name to a peculiar line. On the failure of the counts of this house, in the year 1627, in the person of count Rudolph, one-third of this lordship devolved to the house of Furstenberg, but the other two-thirds were purchased by the elector of Bavaria, of the two elder daughters of the last count; to this the dukes of Wurtemberg indeed would not give their consent, and in the year 1704 took possession of the lordship, but by virtue of the peace of Baden, concluded in the year 1714, were obliged to restore it to the elector of Bavaria.—Also, a town of Bavaria, and capital of a lordship of the same name; 25 miles S.E. of Stuttgart.

WIESENT, a town of Bavaria, in the bishopric of Bamberg; 3 miles E. of Forcheim.

WIESENTHAL, **BOHMUSCH**, a town of Bohemia, in the circle of Saatz; 25 miles N.W. of Saatz. N. lat. $50^{\circ} 23'$. E. long. $12^{\circ} 57'$.

WIESENTHAL, Ober, a town of Saxony, in the circle of Erzberg; 11 miles S.E. of Schwartzenberg.

WIESENTHAL, Unter, a town of Saxony, in the circle of Erzberg. All these towns are very near together, a small brook only separates the Bohemian town from the two German ones; 10 miles S.E. of Schwartzenberg.

WIESENTHAL, a lordship situated between the duchy of Wurzburg, the county of Castell, and the margravate of Anspach. It takes its name from a citadel belonging to the counts of Schonburg.

WIESPINCAN, a river of Louisiana, which runs into the Mississippi, N. lat. $41^{\circ} 22'$. W. long. $91^{\circ} 36'$.

WIESEN,

WIESSEN, a town of Germany, in the county of Rieneck; 10 miles N.W. of Löhre.

WIESTERBURG, a town of Westphalia, in the principality of Halberstadt; 7 miles N.E. of Osterwick.

WIETHEN, a lake of North America. N. lat. 62° 30'. W. long. 99° 50'.

WIETLISBACH, a town of Switzerland, in the canton of Berne; 20 miles N. of Berne.

WIETMARSEN, or WITTMARSCHEIN, a town of Germany, in the county of Bentheim, with an abbey, which formerly belonged to the Benedictines, and was in the 12th century secularized for noble ladies; 4 miles N. of Northorn.

WIFE, Uxor, a married woman; or one joined with, and under the protection of, a husband. See MARRIAGE.

A wife, in our English law, is termed *feme covert*; *femina viro co-operta*; her condition during marriage is called her *coverture*; and, in the judgment of the law, is reputed to have no will, as being supposed entirely under, and subject to, that of her husband: *uxor fulget radiis mariti*.

A man cannot grant any thing to his wife, or enter into covenant with her; for the grant would suppose her separate existence, and to covenant with her would be only to covenant with himself; and, therefore, it is generally true, that all compacts made between husband and wife, when single, are void by the intermarriage. A woman, however, may be attorney for her husband; and a husband may bequeath any thing to his wife by will, for that cannot take effect till the coverture is determined by his death.

From the unity of person that subsists between the husband and wife, in consequence of marriage, it follows, that whatever personal property belonged to the wife before marriage, is by marriage absolutely vested in the husband. In a real estate, he only gains a title to the rents and profits during coverture; for that, depending upon feudal principles, remains entire to the wife, after the death of her husband, or to her heirs, if she dies before him; unless by the birth of a child, he becomes tenant for life by the curtesy. But in chattel interests, the sole and absolute property vests in the husband, to be disposed of at his pleasure, if he chooses to take possession of them: for, unless he reduces them to possession, by exercising some act of ownership upon them, no property vests in him, but they shall remain to the wife, or to her representatives, after the coverture is determined.

There is, however, a considerable difference in the acquisition of this species of property by the husband, according to the subject-matter; viz. whether it be a *chattel real* or *personal*; and of chattels personal, whether it be in *possession*, or in *action* only.

A *chattel real* vests in the husband, not absolutely, but *sub modo*. As, in case of a lease for years, the husband shall receive all the rents and profits of it, and may, if he pleases, sell, surrender, or dispose of it during the coverture: if he be outlawed or attainted, it shall be forfeited to the king; it is liable to execution for his debts; and if he survives his wife, it is to all intents and purposes his own. Yet if he has made no disposition thereof in his life-time, and dies before his wife, he cannot dispose of it by will; for, having never been transferred from the wife, after his death she shall remain in her ancient possession, and it shall not go to his executors.

Thus also with regard to chattels personal (or *choses in action*), as debts upon bond, contracts, and the like; these the husband may have if he pleases; that is, if he reduces them into possession by receiving or recovering them at law:

in which case, they are absolutely and entirely his own: and shall go to his executors or administrators, or as he shall bequeath them by will, and shall not revert in the wife. But if he dies before he has reduced them into possession, so that at his death they still continue *choses in action*, they shall survive to the wife.

Thus in both the species of property the law is the same, in case the wife survives the husband; but, in case the husband survives the wife, the law is very different with respect to *chattels real* and *choses in action*; for he shall have the *chattel real* by survivorship, but not the *chose in action*; except in the case of arrears of rent, due to the wife before her coverture, which in case of her death are given to the husband by the statute 32 Hen. VIII. cap. 37.

As to *chattels personal* (or *choses in possession*), which the wife hath in her own right, as ready money, jewels, household goods, and the like, the husband hath therein an immediate and absolute property, devolved to him by the marriage, which can never again revert in the wife or her representatives.

The wife also, by marriage, acquires a property in some of her husband's goods, called her *paraphernalia*, which shall remain to her after his death, and shall not go to his executors. These, signifying the apparel and ornaments of the wife, suitable to her rank and degree, the husband cannot devise by his will; though during his life perhaps he hath the power (if unkindly inclined to exert it) to sell them or give them away. But if she continues in the use of them till his death, she shall afterwards retain them against his executors and administrators, and all other persons, except creditors where there is a deficiency of assets. And her necessary apparel is protected even against the claim of creditors.

The wife can make no contract without her husband's consent; and, in all law-matters, *sine viro respondere non potest*.

The husband is bound to provide his wife with necessaries by law, as much as himself; and if she contracts debts for them, he is obliged to pay them; but for any thing besides necessaries, he is not chargeable. Also if a wife elopes, and lives with another man, the husband is not chargeable even for necessaries, at least if the person who furnishes them is sufficiently apprized of her elopement.

If the wife be indebted before marriage, the husband is bound afterwards to pay the debt. If the wife be injured in her person or property, she can bring no action for redress without her husband's concurrence, and in his name as well as her own; neither can she be sued, without making the husband a defendant. There is indeed one case where the wife shall sue and be sued as a *feme sole*, viz. where the husband has abjured the realm, or is banished; for he is then dead in law. See CUSTOM of London.

In criminal prosecutions, the wife may be indicted and punished separately; for the union is only a civil union. But in trials of any sort, they are not allowed to be evidence for or against each other. However, where the offence is directly against the person of the wife, this rule has been usually dispensed with; and, therefore, by stat. 3 Hen. VII. cap. 2. in case a woman be forcibly taken away and married, she may be witness against such her husband, in order to convict him of felony. See FORCIBLE Abduction.

In the civil law, the husband and wife are considered as two distinct persons; and may have separate estates, contracts, debts, and injuries; and, therefore, in our ecclesiastical courts, a woman may sue and be sued without her husband.

But, though our law in general considers man and wife

as one person, yet there are some instances in which she is separately considered; as inferior to him, and acting by his compulsion. And, therefore, all deeds executed, and acts done by her during her coverture, are void; except it be a fine or the like matter of record, in which case she must be solely and secretly examined, to learn if her acts be voluntary. She cannot by will devise lands to her husband, unless under special circumstances; for at the time of making it she is supposed to be under his coercion. And in some felonies, and other inferior crimes, committed by her through constraint of her husband, the law excuses her; but this extends not to treason and murder. See *FEME-COVERT*.

The husband also, by the old law, might give his wife moderate correction; but this power of correction was confined within reasonable bounds, and the husband was prohibited from using any violence to his wife. The civil law gave the husband the same, or a larger authority over his wife; allowing him, for some misdemeanors, *flagellis et fustibus acriter verberare uxorem*; for others, only *modicam castigationem adhibere*. But, with us, in the politer reign of Charles II., the power of correction began to be doubted; and a wife may now have security of the peace against her husband, or, in return, a husband against his wife. The courts of law will still permit a husband to restrain a wife of her liberty, in case of any gross misbehaviour. Blackst. Com. book i. book ii.

If a wife bring forth a child during her husband's absence, though of many years; yet if he lived all the time *inter quatuor maria*, within the island, he must father the child; and the child, if first born, shall inherit. See *BASTARD*.

If a wife bring forth a child begot by a former husband, or any other person, before marriage, but born after marriage with another man; this latter must own the child, and that child shall be his heir at law.

The wife, after her husband's death, having no jointure settled before marriage, may challenge the third part of his yearly rent of land, during her life; and, within the city of London, a third part of all her husband's moveables for ever. See *DOWER*, *INTESTATE*, and *CUSTOM of London*.

The wife partakes of the honour and condition of her husband; but none of the wife's dignities come, by marriage, to her husband.

Yet, the husband, who marries a woman seized of lands in fee-simple, or fee-tail, *i. e.* of any estate of inheritance, and has by her issue born alive, which was capable of her estate, shall, on the death of his wife, hold the lands for his life, as tenant by the curtesy of England.

The English laws are generally esteemed by foreigners as very hard, in respect to the women; and yet Chamberlayne is of a very different opinion, asserting, that the condition of wives in England is better than in any other country.

The disabilities to which the wife is subject are for the most part intended for her protection and benefit. So great a favourite (says judge Blackstone) is the female sex of the laws of England.

Tertullian has two books, on the ornaments and attire of wives. In the second, he labours to prove that a Christian wife cannot, in conscience, endeavour to please by her beauty, which she knows to be naturally liable to raise loose desires; and that she ought not only to avoid all affected beauty, but even to conceal and cover her natural beauty.

WIFE, *Mid, Obstetrix*. See *DELIVERY*.

WIFFLISBURG, in *Geography*. See *AVENCHES*.

WIGAN, a borough and market-town in the hundred of West-Derby, and county of Lancaster, England, is seated near the rise of the river Douglas, the banks of which

are noted for a celebrated battle fought between king Arthur and the Saxons, when the latter were defeated. In the time of Henry VIII., Wigan is described by Leland as a "paved town, as big as Warrington, but better builded, and inhabited by some merchants, artificers, and farmers." In its present state, it has a neat though irregular appearance; and has been lately much improved by the opening of two new streets, and the erection of several handsome buildings. An extensive trade is carried on in the manufacture of coarse home-made linens, checks, calicoes, fustians, and other cotton goods. Here are also large brass and pewter works.

Wigan is a borough by prescription, and has had its privileges confirmed by the several charters of Henry III., Edward II., Edward III., Richard II., and Charles II. Its corporate body consists of a mayor, recorder, twelve aldermen, and two bailiffs. Two members are returned to parliament; and the right of election is vested in the free burghesses, in number about 200. The representation of this borough has occasioned some very expensive contests; and it is said to have cost George Byng, esq. 10,000*l.* in his opposition to the interest of sir Fletcher Norton, and Simon Luttrell, esq. Returns appear so early as the 23d and 35th Edward I., after which the privilege was suffered to be dormant for 240 years; no other return being made till 1st Edward VI.

The parish-church is ancient, and considered to be a handsome structure: it consists of a nave, a spacious chancel, and two side-aisles. Among the monuments in the church is one to the memory of sir Roger Bradshaigh, and another to sir William and lady Mabel Bradshaigh. The remains of George Hole, rector of this church and bishop of Chester, are deposited within the communion-rails. He died August 23, 1668. The rectory is one of the best endowed in the kingdom, and the incumbent is always lord of the manor. In the town is a chapel of ease, three chapels for dissenters, and one for Roman Catholics. A town-hall was built in 1721, at the joint expence of the earl of Barrymore and sir Roger Bradshaigh, the then representatives of the borough. A free-school was erected, and liberally endowed, about the beginning of the last century, by voluntary contribution; and upwards of 30 years ago, the same liberality established a blue-coat school for 30 boys. A commodious workhouse has been also built at the expence of the inhabitants of the town, where the necessitous and superannuated poor are comfortably accommodated; industry in the more able are furnished with the means, and the meritorious are encouraged and rewarded. A dispensary has been erected, and is supported by the benevolence of the inhabitants of the town and its vicinity.

At the north end of the town is a monumental pillar, erected in 1679 by Alexander Rigby, esq., then sheriff of Lancashire, to commemorate the valour and loyalty of sir Thomas Tyldesley, who was slain on this spot in 1651, in the action wherein the earl of Derby was defeated by colonel Lilburne.

In a field near Scholes-bridge, contiguous to this town, a spring was lately discovered, which has obtained the name of *Wigan Spa*, or New Harrowgate, as the water resembles that of Harrowgate in Yorkshire.

The population of Wigan, which has been progressively increasing, was, in the year 1801, according to the return to parliament, 10,989; the number of houses, 2236. In 1811, the former had increased to 14,060, and the latter to 2686.

The parish of Wigan contains twelve townships, in three of which, besides that in the town, are chapels of the establishment,

blishment, subordinate to the mother church. Three of these townships, Haigh, Afpinall, and Hindley, are worthy of notice for the production of the finest cannel or candle coal, which is found in large blocks as black as jet, and will bear a beautiful polish. (See *COAL, Cannel.*) The Liverpool and Leeds canal, and the river Douglas, afford navigable communication between this town and several other towns. On an eminence in this township, about a mile north of Wigan, is Haigh-hall, the ancient seat of the Bradshaighs, a family of high antiquity and distinction, but now extinct; from whom it descended by marriage to the earl of Balcarras, who now resides here. This venerable mansion was built at different periods; the chapel is supposed to be coeval with the reign of Edward II. In the vicinity of Wigan originally stood the ancient family mansion of the Marklands.

Four miles west of Wigan is the village of Holland, or Up-Holland, whence the illustrious but ill-fated family of Holland derived their name.

About three miles north of Wigan is the village of Blackrode, at which place the Rev. John Whitaker fixes the Roman station, named Coccium. Mr. Percival and Mr. Watson both agree with Mr. Whitaker in placing Coccium here; but these opinions are satisfactorily refuted by the historian of Whalley, who contends that this ancient station was at Ribchester.—*Beauties of England and Wales*, vol. ix. Lancashire, by J. Britton, F.S.A.

WIGEON PENELOPE, *Anas Penelope* of Linnæus, in *Ornithology*, is a well-known bird. (See *DUCK.*) Its bill is lead-coloured, and the end of it black; the head, and upper part of the neck, of a bright light bay; the forehead paler, in some almost white; the plumage of the back, and sides under the wings, are elegantly marked with narrow black and white undulated lines; the breast is of a purplish hue, sometimes, though rarely, marked with round black spots; the belly white; and the vent-feathers black. In some birds the coverts of the wings are almost wholly white; in others of a pale brown, edged with white; the greater quill-feathers are dusky; the outmost webs of the middle feathers of a fine green, the tips black; the last are elegantly striped with black and white; the two middle feathers of the tail are longer than the others, black, and sharp pointed; the rest ash-coloured; the legs dusky.

The head of the female is of a rusty brown, spotted with black; the back is of a deep brown, edged with a paler; the tips of the lesser quill-feathers white; the belly white. Pennant.

WIGGER, in *Geography*, a river of Switzerland, which runs into the Aar, 3 miles N.W. of Zoffingen.

WIGHT, ISLE OF. See *ISLE of Wight*.

WIGHT, *Isle of*, a county of Virginia, on the right side of James river, about 40 miles long and 15 broad, watered by the Nansemond. It contains 9186 inhabitants, including 4041 slaves.

WIGLEN, a small island in the North sea, near the coast of Norway. N. lat. 65°.

WIGSTADT, a town of Bohemia, in the circle of Koniggratz; 6 miles N.E. of Geyersberg.

WIGSTADTEL, or **WAKOW**, a town of Silesia, in the principality of Troppau; 10 miles S. of Troppau. N. lat. 49° 38'. E. long. 17° 47'.

WIGTON, a town of Cumberland, England, stands in a fine dry open country; and within the last thirty years has been greatly increased in population, from the introduction of manufactures. In the year 1811 its inhabitants amounted to 2977, who occupied 643 houses.

The first manufactories established here were for different kinds of coarse linens; but since the year 1785, this business has received a considerable check by the encouragement given to the various branches of the cotton trade, which flourish in great vigour. In 1790 a manufactory for printing calicoes was established at Spittle, about a quarter of a mile from the town, and seems likely to become an important undertaking, as the goods are in high repute, and the situation extremely convenient for extending the works.

The present church was erected in 1788: its neatness is eminently contrasted with the ancient fabric, which was a dark gloomy structure, built, according to the Chronicon Cumbriæ, by Odoard de Logiz, to whom the barony was given by Waldeof, son of earl Gospatrick. The materials it was constructed with were procured from the Roman station at Old Carlisle, as appears from the stones being marked in a similar manner to those that may yet be obtained there. In removing the foundations of the old tower, two Roman sepulchral inscriptions were discovered. The streets are tolerably spacious, and many of the buildings are handsome and modern. In the year 1723, an hospital was founded here, under the will of the Rev. John Thomlinson, A.M. for six indigent widows of Protestant beneficed clergymen, episcopally ordained; and incorporated by the name of "The Governesses and Sisters of the College of Matrons, or Hospital of Christ in Wigton." The endowment has been augmented by some small benefactions: the allowance to each widow is about eight pounds annually. A free-school was also established here in 1780; chiefly by the contributions of the inhabitants, aided by the benevolence of Dr. Thomlinson's brother. In this town, observes Mr. Gough, was anciently an hospital or free chapel, dedicated to St. Leonard, to which, Mr. Pegge is of opinion, belongs a seal found in Pickering-castle, Yorkshire: it is of wood, and has the representation of the Deity, with the crucifix, circumscribed *Sigillum Wigton*.

About one mile south from Wigton are the ruins of the considerable Roman station, now called Old Carlisle, but generally supposed to have been the Olenacum of the Notitia, where the Ala Herculea were in garrison. Vestiges of ancient buildings are very conspicuous; the foundations of numerous ruined edifices being scattered over many acres, as well within the vallum as on every side, without excepting to the westward, where the ground descends precipitously to the brook Wifa. The station itself occupied an elevated site, and commanded an extensive view north and north-west. Its form is an oblong square 170 paces in length and 110 broad, with obtuse angles, defended by a double ditch and vallum, and having an entrance near the middle of each side. The military way, on which it stands, is very broad and distinct, and leads immediately to Carlisle and the Wall. Within the vallum, a well was discovered a few years ago, about three feet in diameter, and regularly lined with stones. Various inscriptions, sacrificing instruments, coins, altars, small images, statues on horseback, urns, and other vestiges of antiquity, have been found at this station.

Several antiquities, discovered near this place in the course of the last century, have been described in different volumes of the Gentleman's Magazine, particularly in those for the years 1748, 1756, and 1757.

Clea-hall, a seat of sir Henry Fletcher, bart., whose family obtained it by an intermarriage with the female heir of a branch of the Musgraves, stands on a cultivated spot in the midst of an elevated and dreary moor.—*Beauties of England and Wales*, vol. iv. Cumberland, by J. Britton and E.W. Brayley.

WIGTOWN, a royal borough, market-town, and the capital of the shire of the same name, Scotland, is situated on the side of a hill near the confluence of the river Bladenock, at the distance of 105 miles S.W. by S. from Edinburgh. It is of very high antiquity, and appears to have received its charter of incorporation from king Robert Bruce. The civil government is vested in a provost, two baillies, and twelve counsellors. Wigtown unites with the boroughs of Whitehorn, New Galloway, and Stranraer, in sending one member to the British parliament. The church is in good repair. A well-supplied market is held weekly, and five fairs annually. Being the shire-town, the sheriffs' courts are holden here. A grammar-school is established, and well conducted. The parish of Wigtown is in the form of an oblong-square, extending five miles in length and four in breadth, and comprehends about 5500 acres. The climate is cold, but remarkable for producing health and longevity. A great diversity prevails in the soil and surface: towards the south it is interspersed with hills, which are almost entirely arable, with a dry, light, and fertile mould; the north-west corner is more varied and less productive; and the north-west part is principally covered with moss, and appears to have been formerly an arm of the sea. The greater part is inclosed; and the spirit of agricultural improvement is much encouraged. Particular attention is paid to the repairs of the roads and bridges. The population of the parish, at the enumeration of the year 1811, amounted to 1711. In the western part of the parish is a large circle of stones, called "The Standing Stones of Torhouse," which is supposed to have been a temple of the Druids.—*Beauties of Scotland*, vol. ii. Wigtownshire. *Gazetteer of Scotland*, 1806. *Carlisle's Topographical Dictionary of Scotland*, 2 vols. 4to. 1813.

WIGTOWN Bay, a bay of the Irish sea, on the S. coast of Scotland, at the mouth of the river Cree, between the counties of Wigtown and Kircudbright.

WIGTOWNSHIRE, the western part of the district of Galloway, forms the south-western extremity of Scotland. It is bounded on the E. by Kircudbright, on the S.E. by Wigtown bay, on the S. and W. by the Irish sea, and on the N. by Ayrshire. It is of an irregular figure, of which the greatest length is about thirty miles, and the breadth nearly twelve. The superficial contents are 469 square miles, or 238,721 Scottish acres. The shire comprehends three royal boroughs, Wigtown, Stranraer, and Whitehorn; also the town of Portpatrick, and thirteen other parishes. By the population return of the year 1811, the number of houses is stated to be 5402; that of the inhabitants 26,891; namely, 12,205 males, and 14,686 females. The shire sends one member to the imperial parliament, and the three boroughs unite to send another. Wigtownshire is one of the most level counties in Scotland; and the hills are in general free from projecting rocks, and very accessible to the plough. The navigation along the coast is so uninterrupted, that it may be regarded as one of the most eligible situations in the island, in point of natural advantages, for a trading district. The richest lands lie upon the coast, where the means of improvement are to be met with in the greatest abundance: the inland and more elevated parts have a considerable mixture of heath and moss, but are all in a greater or less degree susceptible of improvement. There are few mountains in Wigtownshire. The Cairnpat, near Portpatrick, is one of the most considerable: it rises 800 feet above the level of the sea. The summit bears all the marks of having been a military station, being surrounded by three stone walls, with very ample spaces between them;

and commands a prospect of Loch-ryan, and Luce bay, which by advancing inland form the peninsula, called the Rhynns of Galloway, in which Portpatrick is situated.

The rivers of this county are of no great importance. The Cree forms part of its eastern boundary. The next stream to the westward is the Bladenoch, which rises from a lake called Loch Macbeary, situated mostly between the two parishes of Kirkowen and Penningham. There are several small islands in it; upon the largest of which are the remains of a considerable building and small garden. The river Bladenoch, which has its source in this lake, runs in a south-easterly direction for about two-thirds of its length; after which it takes a more easterly course, and empties itself into the bay of Wigtown: its whole length is about twenty-four miles. Tarff is a stream which rises in the precincts of Ayrshire, and after a course of twelve miles, in a south-easterly direction, falls into the Bladenoch in the parish of Kirkowen. Luce-water is a small river, which runs into the great bay of that name. Salmon are caught in it; and it is observed that the skin of the salmon, when it first goes up the river, which is deeply tinged with moss, is of a silvery colour, but after remaining some time, it becomes of a brownish-yellow.

Wigtownshire has several fresh-water lakes, but none of particular importance. In the parish of Sorbie is one of three miles in circumference, well stored with pike, perch, and eels. It is called Dowalton lake, because the ancient powerful chiefs, the Macdowals, had their residence near it. In the parish of Ince are fifteen lakes, of different degrees of extent, abounding with fish of several kinds, and frequented by a variety of water-fowls. Swans emigrate from Ireland, particularly in severe winters, and continue in these lakes till spring. The shire of Wigtown is deeply penetrated by navigable bays. Wigtown bay and Luce bay advance in a direction nearly parallel far into the country towards the north. At the same time, from the northern part of the county, the long and narrow bay called Loch-ryan advances southward towards the bay of Luce, and peninsulates an extensive territory, which appears to have long remained divided from the rest of Scotland. Loch-ryan is a beautiful as well as a safe and commodious bay for shipping. It is about ten miles in length from north to south: the entrance into it is nearly two miles broad. It is bounded on the east by the parish of Balantrae, in Ayrshire, and on the west by Millar Point, a headland in the parish of Kirkholm. About three or four miles from the mouth of the loch, on the east side, is the little village of Cairn; contiguous to which is a commodious bay with good anchoring ground, and depth of water sufficient for ships of any burthen; and all vessels entering into or coming out of the frith of Clyde seek this bay in stormy weather. King William's fleet anchored here in their passage to Ireland. Besides the Cairn bay, there are several other good anchoring bays in the loch. Luce bay, which advances from the south towards Loch-ryan, is far more extensive. In dark and hazy weather, vessels often mistake Luce bay for the Irish channel, and when keeping a northerly course, sometimes run on shore, before the error is discovered. The bay of Luce contains a great variety of lesser bays, some of which are capable of being converted into convenient harbours; and mariners acquainted with them find anchoring places, in which they are in safety from almost every wind. The coast around the bay of Luce is very various: in some places it consists of a fine gravel beach; at other points steep rocks project into the sea, forming a bold inaccessible shore. The most southern point of the coast, or rather of Scotland, is called the Mull
of

of Galloway: in the western side of it rises a very elevated coast: it is about the extent of a mile, and projects itself as the boundary between the Irish sea and the bay of Luce. In a high westerly wind a prodigious swell of sea rolls round the point, and is then awfully grand. Here the sea has formed caverns, which are rendered dreadful by a setting-in tide and a strong westerly wind. The noise is like loud claps of thunder. Ships pass and repass this point from England, Ireland, and the west of Scotland.

Though the *agriculture* of this county is yet but in an inferior state, great exertions are making to bring the soil under the best management of which it is capable. Still, however, the defects of the soil, added to the imperfect state of the husbandry which has hitherto existed, greatly depress the value of the territory. The earl of Stair's estate is said to extend to about 55,000 acres, but produces an annual rental of no more than 11,000*l.* sterling. There are in this county great tracts of flow moss, of that soft consistence which renders it almost inaccessible, and of no utility either for agriculture or pasturage. Little hopes are yet entertained of the practicability of improving this sort of territory. But it is confidently asserted, that an immense field of moss of this description below Newton Douglas might by proper management be floated into the sea, leaving some thousand acres of rich clay behind. The great trunks of trees that are found in the mosses of this county, afford full proof of its having been formerly covered with wood. The renewal of the forests, however, proves a very arduous task; and in certain exposures on the coast has repeatedly baffled the hopes of the most ingenious and attentive planters. Wood, corn, and potatoes, in this exposure, are more or less injured, according to their vicinity to the sea; whereas, when protected from it, they are found to grow with their usual vigour. Shelter, therefore, either natural or artificial, must be had on this coast before wood can be planted with any chance of success. Scottish firs, which serve to nurse up plantations in many other parts of the country, are unfortunately found to thrive worse here than any other species of wood. Under this difficulty, the earl of Galloway fortunately discovered the valuable properties of the pinaster, or maritime pine, which he observed to grow with a degree of luxuriance superior to any other in his plantations. He has since increased the propagation of that tree, and now finds that under its protection, almost any other wood may be planted with success. Attempts are making to introduce dairy-farms into this county, for the purpose of supplanting the universal practice of breeding cattle. One farmer, upon this plan, has no less than eighty milking cows: he uses his whole milk in the manufacture of cheese, which he exports to the Clyde. A remarkable breed of small white-faced sheep, peculiar to the coast of this county, deserves notice. It is called the Mochrum breed. These are said to be of Spanish extraction, an idea the more readily adopted, from the quality of their wool, which is of the fine clothing sort, of a texture superior to most in Scotland, and but little inferior to real Spanish. This breed, which is at present of an under size, is well-shaped, hardy, and found by proper attention to improve much, both in weight of carcase and wool.

The mineral productions of the county are but few: the parish of Kirkmaiden, which forms the southern part of the peninsula that bounds the bay of Luce on the west, contains valuable quarries of slate, of which considerable quantities are wrought and sent to market. Here are several natural caverns, in one of which is a petrifying water, dropping from the roof. In the parish of Inch, situated

upon Loch-ryan, are several mineral springs: one, with a sulphurous impregnation, has been found useful in stomachic and scorbutic complaints. There is also a chalybeate spring. Some appearances of coal have been thought to exist here; but that valuable mineral has hitherto been sought in vain. In this quarter, towards Ayrshire, is a bold rocky shore, containing several natural excavations or caverns, extending eighty or an hundred yards under ground. The parish of Whitehorn, in the south-eastern part of the county, produces very fine variegated marble, and also slate of a strong quality. The chief natural defect incidental to this county is the want of coal, a defect common to it with almost the whole of the southern border of Scotland. Was it not for this check to the establishment of manufactures, it might be likely to assume some share of commercial importance. Though of small extent, it has an ample sea-coast, which affords great facility for exporting the produce of its agriculture and dairies. This facility is so great, that the inhabitants of Wigtownshire are sometimes in dread of scarcity, in consequence of the greater part of their produce being carried to Glasgow, Paisley, or Liverpool, where a market is always to be obtained.—*Beauties of Scotland*, vol. ii. Wigtownshire, 1805. *Gazetteer of Scotland*, 1806.

WIGWORM POINT, a cape on the coast of Patagonia, in the straits of Magellan; 3 miles N.E. of Cape Providence.

WIHACS, or WIHATS. See BIHACS.

WIHENAIS, a town of Sweden, in the province of Savolax; 40 miles N. of Christina.

WIHR, or WEYER, a town of France, in the department of the Upper Rhine; 6 miles W. of Colmar.

WIHRBACH, a river of France, which runs into the Rhine, 7 miles above Germerheim.

WIKES, in *Agriculture*, a term used to signify temporary boundaries or marks, set up in order to divide the swaths to be mown; such as the boughs of trees, in the common fields and meadows in different districts; as well as such boughs when set upon hay-cocks and stouks of corn for the taking of tithes, and other such purposes.

WIKINISH CREEK, in *Geography*, a river of Pennsylvania, which runs into the Susquehanna, N. lat. 40° 32'. W. long. 77° 1'.

WILAUF, a river of Wurtemberg, which runs into the Rens, near Schorndorf.

WILBASSEN, or WILBADESSEN, a town of Westphalia, in the bishopric of Paderborn; 8 miles S.E. of Dringenberg.

WILBRAHAM, a township of Massachusetts, in the county of Hampshire, with 1776 inhabitants; 10 miles E. of Springfield.

WILBURG, a citadel of Austria; 8 miles E.S.E. of Ips.

WILBYE, JOHN, in *Biography*, one of our best madrigalists of queen Elizabeth's reign. In his first set, the following are well-known: "Lady, when I behold the roses sprouting;" and "Flora gave me fairest flowers:" but, "Hard by a crystal fountain," which, according to Hearne, (*Lib. Nig. Scacc.*) used annually to be sung by the fellows of New college, Oxon, we are unable to find. Those words are adjusted to the music of Giov. Croce, in the second book of *Musica Transalpina*, and are set by Morley in the *Triumphs of Oriana*; but appear not either in the first or second set of Madrigals published by Wilbye, and we know of no other.

WILD ALBEN, in *Geography*, a mountain of the duchy of Stiria; 7 miles N.N.W. of Muertzenschlag.

WILD *Angelica, Basil, Briar, Campion, Carline Thistle, Carrot, Chervil, Cistly, Climber, Lettuce, Liquorice, Madder, Marjoram, Melic, Mint, Mustard, Oat, Radish, Rape, Rocket, Tare, Thyme, and Vine, in Agriculture.* See WEED.

WILD-Fire, or *Erysipelas*, a disease in sheep, which affects the skin, and which, if not well attended to, is liable to spread very quickly among the flock. It is attended with considerable inflammation in many cases, though but seldom with blisters over the body. It commonly takes place towards the latter end of summer, and does not continue more than eight days at a time, although such sheep as are once affected with it are very liable to have it again. It was formerly a practice with shepherds to bury the sheep that were affected with this disease in the ground at the door of the fold, with their feet upwards, which, they believed, acted as a charm to drive it from the flock. But this folly is now done away with.

In the cure of this affection of the skin, recourse may be had to evacuations from the bowels by the use of calomel, or purging-salts, dissolved in warm water, for three or four days; then sulphur with nitre may be given in pretty full doses, cooling washes being used at the same time. Strengthening remedies should afterwards be employed, such as oak, or other barks of the same nature. During the cure, the sheep should be kept from being too much exposed to cold, and in a dry sound pasture, being well fed when necessary.

WILD-Fire, *Ignis Gregalis, or Gracus.* See WILD-FIRE.

WILD-Fire Arrows, such as were trimmed with wild-fire, and shot burning, to stick in the sails or rigging of ships in a fight. See FIRE-ARROW.

WILD-Fowl. See WATER-FOWL, and DECOY.

WILD-Goose, *Anas Anser.* See DUCK.

WILD-Goose Chase. See CHASE.

WILD-Honey. See HONEY.

WILD-Land, *Reclaiming of, in Agriculture.* See RECLAIMING LANDS.

WILD-Olive. See ELÆAGNUS.

WILD Service-Tree, in *Agriculture and Gardening*, a deciduous tree of considerable growth, which is much cultivated in the field and pleasure-ground. It has been observed, that this tree is sometimes planted in orchard-grounds among fruit-trees, but that it should be put in pleasure-grounds, plantations, or on lawns, for its ornamental effect in the autumnal season.

If trained up with straight clean stems, service-trees will grow to the height of thirty or forty feet; in that case, they should be planted among forest-trees, or in the back parts of large shrubberies. But those who wish to plant them as flowering shrubs must head them down when young, to make them throw out horizontal shoots; they may then be planted among the middling-sized shrubs, which will make a beautiful variety, both when in flower, and when bearing fruit. These trees grow to a considerable size when properly managed, and are very much used by wheelers and others, on account of the wood being all, what they call, heart-wood.

The fruit has been found excellent for feeding game, and other sorts of birds and fowls.

WILDAU, in *Geography*, a town of the duchy of Stiria, on the west side of the Muehr; 12 miles S. of Gratz.

WILDBAD, a town of Wurtemberg, celebrated for its warm-baths; 30 miles N.E. of Strasburg. N. lat. 48° 40'. E. long. 8° 26'.

WILDBERG, a town of Wurtemberg, on the Nagold; 3 miles N. of Nagold. N. lat. 48° 33'. E. long. 8° 48'.—Also, a town of Prussia, in the province of Oberland; 12 miles S. of Ortelburg.

WILDBERG, or *Wildbergen*, a town of the Middle Mark of Brandenburg; 28 miles N. of Brandenburg. N. lat. 52° 55'. E. long. 12° 38'.

WILDE, JAMES, in *Biography*, a Swedish historian, was born in Courland in 1679, and educated at Riga; and having quitted that city in 1695, he sought farther improvement in several German academies, graduating M.A. at Griefswald. At the age of 21, such was his proficiency in various branches of literature, he was appointed co-rector of the cathedral school at Riga, and soon after teacher of politics, history, and eloquence, in the royal gymnasium of that place. Qualified by his talents and acquirements for a higher rank in the department of instruction, he was invited, in 1703, to be professor of history in the academy of Pernau; but declining this office, he was, in the following year, nominated by Charles XII. to fill the chair of Latin eloquence and poetry, which he occupied for five years. During his stay at Aix-la-Chapelle, which he visited in 1709 for the recovery of his health, the Russians made an irruption into Livonia, and he lost his library, with all his documents and papers. From hence, instead of returning to his native country, he proceeded to Stockholm, and offered his services to the senate. Such were the existing troubles at that time, that it was not till the year 1713 that government appointed him to be professor of eloquence and poetry at Griefswald. But he preferred a humble and more private situation as tutor to the two sons of count Cronhielm, with whom he made a tour to England, Holland, France, and Germany. Pursuing a similar tour with a young Holstein count, and becoming acquainted with the duke of Holstein, he was appointed his cabinet-secretary, in connection with the professorship of the law of nature and nations at Kiel. And in the same year king Frederick made him historiographer to the kingdom; on which office he entered at Stockholm in November 1719. His works were numerous and learned; but his constitution was feeble, so that he sunk under his labours, and died in 1755. Although he was more than thirty years old when he went to Sweden, he obtained a thorough acquaintance with the Swedish history: he was also well acquainted with the public law of Germany; and in his earlier years he had raised himself by writing Latin poetry. He was also a good philosopher, and a theologian, and often preached. His memory was singularly retentive; and this served him in various works which he composed after having lost his sight in 1741. Many of his works were lost at the capture of Pernau. During his tour with the sons of count Cronhielm, he published at Frankfurt, in 1717, “*Diatriba de Jure et Judice Legatorum á Stephano Cassio;*” *Sueciæ Historia Pragmatica, quæ vulgo jus publicum dicitur, &c.*” Holm. 1731, 4to.; “*The Foundation, Nature, Origin, and Antiquity of the Swedish Laws, with an Account of the Changes and Alterations which have been made in them,*” *ibid.* 1736, 4to.; “*Puffendorf’s Introduction to the History of Sweden, with Additions, Proofs, and Notes,*” by J. Wilde; “*I. Part,*” *ibid.* 1738, 4to.; “*II. Part,*” *ibid.* 1743, 4to.; “*Preparatio hodegetica ad Introductionem Puffendorffii in Svethici status Historiam, &c.*” *ibid.* 1743, 4to. Gen. Biog.

WILDE, in *Geography*, a river of Prussian Lithuania, which runs into the Ruffe.

WILDE.

WILDEBERG, a town of Pomerelia; 2 miles S. of Marienburg.

WILDEMAN, a town of Westphalia, in the principality of Grubenhagen, near which are some mines of silver and lead; 6 miles S.W. of Goslar.

WILDENBERG, or WILDENBORG, a town of the duchy of Berg; 10 miles E. of Homberg.

WILDENBERG, a town and castle of France, in the department of the Rhine and Moselle; 10 miles W. of Kirn.

WILDENBRUCH, a town of Hinder Pomerania; 5 miles S. of Balm.

WILDENECK, a town of the duchy of Carniola; 10 miles S.E. of Stein.

WILDENFELS, a town of Saxony, in the circle of Erzgebirg; 5 miles S.E. of Zwickau.—Also, a citadel in the territory of Nuremberg; 3 miles W.S.W. of Bezenstein.

WILDENFURT, a town of Saxony, in the circle of Neustadt; 2 miles N.N.E. of Weyda.

WILDENHOF, a town of Prussia, in Natangen; 23 miles S. of Brandenburg.

WILDENS, JOHN, in *Biography*, was born at Antwerp in 1584. He became an admired painter of landscapes, but under whom he acquired the art is unknown. He appears to have been a diligent observer of nature, and to have studied much in the open air; as his studies of forests, fields, &c. are numerous. When he had obtained considerable reputation, his talents introduced him to the notice of Rubens, who employed him to assist in executing the landscape parts of back-grounds, which he did with so great felicity, that there appears no dissimilarity in styles in the pictures on which they both took their respective parts. Two of his best pictures are in the chapel of St. Joseph at Antwerp, embellished with figures by Lang Jan: the subject of one is the Flight into Egypt, and of the other a repose. He died in 1644, aged 60.

WILDENSCHWERT, in *Geography*, a town of Bohemia, in the circle of Chrudim; 9 miles E. of Hohenmaut.

WILDENSTEIN, a town of Germany, in the margravate of Anspach; 7 miles S.E. of Creilheim.

WILDENTHAL, a town of Saxony, in the circle of Erzgebirg; 7 miles S.S.W. of Schwartzenberg.

WILDERNESS, in *Gardening*. There is nothing so great an ornament to a large garden as a wilderness, when properly contrived, and judiciously planted.

The wilderness should always be proportioned to the size of the garden, and should never be situated too near the house: because the trees perspire so large a quantity of watery vapours, as makes the air very unwholesome: though vegetables serve, as modern experiments have sufficiently ascertained, to purify and meliorate the air. See AIR.

The wilderness should never be so placed as to block up a good prospect; but where the view naturally ends with the verge of the garden, or little more, nothing terminates it so well as a fine plantation of trees. The size of the trees should be considered, and tall growing ones should be planted in larger places; smaller, in less extensive; ever-greens also should be kept by themselves, and placed most in sight, not mingled confusedly among the trees which cast their leaves. The walks should be large and not numerous; the large walk is best made serpentine, and this should not be entered upon in the grand walks of the garden, but by some private walk.

It is too common a method to dispose the trees in wildernesses, in form of regular squares, triangles, &c. but this

is faulty; for as nature should be studied in these works of fancy, the most irregular is the most pleasing plantation. The walks for the same reason are much more pleasing when they run in wild meanders, than when they intersect one another in studied and regular angles. The winding walks should be made to lead to an open circular piece of grass, with a statue, an obelisk, or a fountain: or, if an opening large enough for a banqueting-house be contrived in the middle, it will afford a very pleasing scene. The trees should gradually rise from the sides of the walks and openings, one above another, to the middle of the quarters, where the largest trees should stand, by which means the heads of all the trees will appear in view, but their stems will not appear in sight.

Not only the growth of trees is to be considered in the planting of a wilderness, but their nakednesses are to be considered and hid. The larger growing trees are allowed a proportionable distance, and their stems hid by honey-suckles, roses, spiræas, and other low-flowering shrubs. These may also be planted next all the walks and openings; and at the foot of these, near the walks, may be set rows of primroses, violets, and daffodils, with other the like flowers; behind the first rank of lower flowering shrubs should be planted those of a somewhat higher stature, as the *althæa-frutices*, the cytifuses and guelder-roses; and behind these may be rows of the tallest flowering shrubs, as the lilacs, laburnums, and the like; and behind these, the heads only of the lower growing trees will appear, which should be backed gradually with those of higher growth to the centre of the quarter; from whence the heads of the trees should descend every way to the walks, or openings. The grand walks and openings should always be laid with turf, and kept well mowed; but, beside these, there ought to be smaller serpentine walks through the several quarters, where persons may retire for privacy; these should be left with the bare earth, only kept clear of weeds, and laid smooth.

These walks should be made as winding as possible, and a few wood-flowers planted along their sides will have a very good effect. The ever-greens should be allotted a peculiar part of the wilderness, and such as fronts the house; and in the planting of these, the same regard is to be had to their growth, that the tallest trees be planted hindmost, and their stems hid by shorter ones, and so on, down to the verge: as in the first row may be planted laurustines, boxes, spurge, laurels, junipers, and favins; behind these, laurels, hollies, and arbutuses; next behind these, yews, alaternusses, phillereys, cypresses, and Virginian cedars; behind these, Norway and silver firs, and the true pine; and finally, behind these, the Scotch pine and pinaster. These will have a very beautiful appearance, as their tops will only be seen, and make a sheet of green, which may also be very beautifully varied, from the artful admixtures of the several shades of green which the various plants have.

In all these plantations, the trees, however, should not be set in formal stiff rows, but in a loose variety, proportioned to their manner of growth. Miller.

WILDERSDÖRF, in *Geography*, a town of Austria, on the Zeya; 8 miles W.S.W. of Zisterdorf.

WILDESHAUSEN, a town of Westphalia, with a district formerly belonging to the archbishopric and duchy of Bremen, and afterwards to the duchy of Brunswick, in which it is insulated. It is situated on the Hunte, and contains about 312 houses. The inhabitants are partly Roman Catholics; in the bailiwick are 30 villages; 20 miles S.S.W. of Bremen. N. lat. 52° 52'. E. long. 8° 27'.

WILDING, in *Rural Economy*, a four austere sort of apple, often used with others that correct these qualities, for making home cyder. See **CYDER**.

WILDING, *Royal*, an excellent cyder-apple. It is said, in the Gloucester Report on Agriculture, to be a native of Dimock; that it is a free, clean, and handsome grower; makes excellent cyder, is a great favourite among the planters in the upper part of the forest-district of that county, and is much introduced in the vale, on the east side of the Severn. See **CYDER**.

WILDS, a term used by our farmers to express that part of a plough by which the whole is drawn forwards.

The wilds are of iron, and are of the form of a gallows, whence they are by some called the gallows of the plough, but improperly; the gallows of the plough being properly that part formed by the crow-staves, and the transverse piece into which they are mortised at the top. The wilds consist of two legs, and a transverse top-piece: one of the legs, and the top-piece, are all of one piece of iron; and the other leg, which is loose, has a hole in the top, into which the end of the transverse piece is received: both these legs pass through the box of the plough, which is that transverse timber through which the spindles of the wheels run. These legs are pinned in behind the box with iron pins: the holes through the box at which these legs pass, are not made at right angles, but slanting upwards, so that the forepart of the wilds is higher than the hinder part; were it not for this, the upper part of the crow-staves would lean quite back when the plough is drawn.

The use of the notches in the wilds is to give the plough a broader or narrower furrow; if the links are moved to the notches on the right-hand, it brings the wheels toward the left, which gives the greater furrow; and, on the contrary, a smaller furrow is made when the links are moved to the notches on the left. The legs of the wilds should be nineteen inches, and their distance eight inches and a half; they must be made strong, and the links must be placed in different notches, that the front of the plough may be kept steady, and the wheels not be drawn one before the other. These links are of iron also, and are each six inches and a half long, and to these are fastened the chains of the harness, by which the whole plough is drawn along.

WILDSAUBACH, in *Geography*, a river of Germany, which runs into the Elbe, 6 miles below Dresden.

WILDSEE, a lake of the duchy of Stiria; 8 miles E. of Neumarck.

WILDSHUT, a town and castle of Bavaria; 5 miles N.N.W. of Lauffen.

WILDSTADT. See **WILLSTADT**.

WILDUNGEN, a town of Germany, in the county of Waldeck; 7 miles S.S.E. of Waldeck. N. lat. $51^{\circ} 7'$. E. long. $9^{\circ} 8'$.

WILEHNGEN, a town of Switzerland; 9 miles W. of Schaffhausen.

WILEIA, a town of Samogitia, on the Niemen; 25 miles S.S.E. of Rosienne.

WILF, in *Agriculture*, a term used provincially to signify the white willow. See **WILLOW**.

WILFERSDORF, in *Geography*, a town of Austria; 4 miles W. of Brugg.

WILHELMSDORF, a town of Prussia, in Oberland; 13 miles S. of Holland.

WILHELMSHOF, a town of Germany, in the duchy of Anhalt Bernburg, near Hartzgerode.

WILHELMPURG, a town of Austria; 8 miles S. of St. Polten.

WILHELMSTEIN, a town of France, in the department of the Roer; 7 miles S.W. of Juliers.

WILHELMSTHAL, or **NEUSTADTEL**, a mine-town of Silesia, in the principality of Glatz; 15 miles S.E. of Glatz. N. lat. $50^{\circ} 3'$. E. long. $16^{\circ} 42'$.

WILIA, a river of Lithuania, which runs into the Niemen, near Kowno, in the palatinate of Troki.

WILINGO, a town of Sweden, in the province of Schonen; 7 miles N. of Helsingborg.

WILITZ, a town of Bohemia, in the circle of Kaurzim; 5 miles N.N.W. of Kaurzim.

WILKES, **JOHN**, in *Biography*, was born in London in 1727, and finished his studies at the university of Leyden. Soon after his return to England, he married a Miss Mead, who was a lady of large fortune, and settled at Aylesbury. This lady, though highly respectable both in her character and connections, and belonging to a dissenting family as well as himself, was older than he, and in other respects an unsuitable wife, so that the attachment was originally formed, on his part, from lucrative motives: one daughter was the fruit of this connection. Mr. Wilkes, thus furnished with the means of profusion, lived in an expensive style, and being little anxious about domestic happiness, associated with the gay and licentious, to whose habits and manners his principles and character were sacrificed. Urged by his partial friends who thought him qualified for public life, he offered himself, in 1754, as a candidate for the town of Berwick, but his views were disappointed. In this and in several other instances, he counteracted the inclinations and wishes of his wife, so that their continued connection was a source of disquietude, and they determined to separate. In 1757 he was returned as a member for the borough of Aylesbury, the consequence of which was an increase of expenditure, that involved him in pecuniary embarrassments, and led him to dishonourable practices, and particularly to an attempt of freeing himself from the obligation of paying his wife's annuity, in which he failed of success. His parliamentary patron was earl Temple, by whose influence he was chosen representative for Aylesbury; and from whose interest he expected to obtain some place under government, which the perplexity of his circumstances rendered particularly desirable. But he was once and again disappointed; and he ascribed his failure to the interference of lord Bute. In 1762 he connected himself, as a political writer, with lord Temple and Mr. Pitt, and defended them, whilst he exposed the ministry, on occasion of the rupture with Spain, in a pamphlet entitled "Observations on the Papers relative to the Rupture with Spain." This publication was followed in 1763 by an ironical dedication to lord Bute, of Ben Jonson's "Fall of Mortimer," in which he indulged unrestrained levity against the "favourite," as he was called, and his antipathy to the Scottish nation; which was further manifested in a periodical paper called "the North Briton," commenced in 1762, and intended to counteract "the Briton," which Smollet conducted in defence of lord Bute's administration. The North Briton, however, was written with a spirit so consonant to the sentiments of the public at that period, that it probably contributed to the resignation of that nobleman in April 1763. The 45th number of this periodical work was published on the 23d of April, and contained so severe and sarcastic a comment on the king's speech, that his ministers, under the sanction of the crown-lawyers, determined upon a prosecution: and the home secretary of state, lord Halifax, issued a "general warrant;" i. e. a warrant, in which no particular names were specified, for the apprehension of the authors, printers, and publishers of that paper. As soon as it was discovered that Wilkes

had given orders for the printing, he was taken into custody, and brought before the two secretaries of state. Perfectly self-possessed, and avowing the illegality of his arrest, he refused to answer any interrogatories; and a habeas corpus which had been sued out for him being evaded, he was closely confined in the Tower. However, he was soon after brought by habeas corpus before the court of common pleas, when lord chief justice Pratt declared the opinion of that court against the legality of his commitment, so that he was discharged amidst the acclamations of the audience and of the populace. In the course of these proceedings he was deprived of his commission as colonel, by the king's order; and his patron, lord Temple, lost his post of lord-lieutenant of the county. This nobleman, at his own expence, availed himself of the legal decision against general warrants, and commenced actions against the king's messengers, the secretaries, the under secretary, and the solicitor of the treasury; in all which the prosecutors obtained damages, which were paid by the crown, in consequence of an express order of council. Thus the doctrine of the illegality of such warrants was established, and for this accession to the cause of liberty the public were indebted to John Wilkes, lord Temple, and lord chief justice Pratt, afterwards lord Camden. Wilkes, not satisfied with this triumph, proceeded, against the advice of friends, to set up a press in his own house, and to reprint the *North Briton*; for which he was again prosecuted to conviction. Having withdrawn to France in 1763, he was expelled from the house of commons, because he did not appear to answer the charges that were produced against him. The next attack that was directed against him was occasioned by his printing an indecent and profane piece, called "*Essay on Woman*," and said to have been written by Mr. Potter, son of the archbishop of the same name; and as some scandalous reflexions on a bishop were introduced in this piece, complaint of breach of privilege was made in the house of lords; and on a prosecution, he was found guilty of both the crimes of blasphemy and libel. By his continued absence, he incurred the penalty of outlawry. Upon a change of ministry he returned to England, and delivered himself to custody; and confiding in his popularity, he offered himself as a candidate to represent the city of London; but failing in this object, he was immediately elected for the county of Middlesex. Although his sentence of outlawry was reversed as illegal, he was condemned for his two libels to an imprisonment of 22 months, and a fine of 1000*l.* In 1769 he was charged with being the author of a pamphlet relating to the riots, occasioned by his imprisonment, and expelled from the house; and being immediately re-elected, he was declared incapable of a seat in the house during the existing parliament. He now became popular as the martyr of liberty, and large sums were collected towards the payment of his debts. He was again re-elected, and his election was declared void. At the next election, the court-candidate, colonel Luttrell, whose votes were about a fourth of those of Mr. Wilkes, was declared the fitting member. This measure caused dissatisfaction and complaint through the country, and produced petitions for the dissolution of parliament. Wilkes, though excluded from parliament, was chosen an alderman of the city of London; and in the exercise of his office as a magistrate, he resisted with his usual spirit exactions of authority which he considered as illegal; and actually liberated one of the printers of newspapers in which the speeches of members of parliament were detailed, and who had been arrested by royal proclamation. Two others were released by lord mayor Crosby and alderman Oliver, who being members of the house were committed to the Tower. Wilkes

was ordered to attend at the bar of the house; but in a letter to the speaker, he objected, that in the order for attendance, no notice was taken of his being a member of the house, and his attendance in his place had not been desired, which forms, he said, were essential: he also demanded his seat, and then he would give a full account and justification of his conduct. The house, sensible of the difficulty to which it had subjected itself, saved its authority by adjourning for the day on which Wilkes was ordered to attend. In 1772 Wilkes was chosen one of the sheriffs for London and Middlesex, and in 1774 lord mayor of London. Having conducted himself with propriety and reputation in his public offices, he was re-elected in 1776 a representative for the county of Middlesex; and was allowed to take his seat without opposition. In parliament, he opposed the measures that occasioned the American war; and on the accession of the Rockingham administration, he carried his motion for rescinding the decision of the house of commons, which gave Luttrell a seat by a minority of votes. In 1779 he succeeded in his application for the office of chamberlain in the city of London, and retained it during the remainder of his life. Tired of political conflicts, the latter years of his life passed off without much notice, so that, to adopt his own expression, he was an "extinguished volcano;" and he expired at the house of his daughter in 1797, in the 73d year of his age. His private history affords no memorial that is either amusing or instructive. The early errors of his conduct cast a shade over his character. His literary talents and attainments, devoted as he was to pleasure, and engaged in business, never attracted much notice; though as a companion he knew how to render himself agreeable. Although his patriotism might possibly originate in disappointed views and expectations, he was consistent and steady in maintaining the cause to which he was attached; and he was, either intentionally or incidentally, and by an intrepidity and self-possession which he possessed in an eminent degree, the instrument of gaining some important advantages to public and private liberty. *Alm. Mem. of Wilkes. Ann. Reg. Gen. Biog.*

WILKES, in *Geography*, a town of Ohio, in Gallia county, with 187 inhabitants.—Also, a county of the state of Georgia, bordering on South Carolina, containing 7066 inhabitants. Tobacco is the chief produce, of which 3000 hogheads were exported in 1788.—Also, a county in the N.W. corner of North Carolina, with 7247 inhabitants, including 790 slaves.—Also, a town of North Carolina; 50 miles W. of Salem.

WILKESBARRE, formerly WYOMING, called also *Wilkesburg*, a town of Pennsylvania, and chief town of Luzerne county; situated on a plain, bounded on one side by the Susquehanna, and on the other by a range of mountains, and containing about 150 wooden dwelling-houses, a church, court-house, and gaol, with 1225 inhabitants. A dreadful massacre was committed in this place, during the American war, by the Indians under the command of colonel Butler, which is recorded in most histories of that war, and which will ever remain a blot on the English annals. Several of the houses, to which the unfortunate victims retired to defend themselves on being refused quarter, are still standing, perforated in every part with balls; the remains of others that were set on fire are also still to be seen, nor will the inhabitants on any account suffer them to be repaired. N. lat. 45° 13'. W. long. 75° 50'. *Weld's Travels*, vol. ii.

WILKINS, DAVID, in *Biography*, a learned antiquary, was born in 1685, and in early life more than once made the tour of Europe, acquiring a knowledge of most modern languages. In 1715 he was appointed by archbishop Wake

keeper of the Lambeth library, of which he made a catalogue, and for his three years' labour in this way he was recompensed with several preferments, such as the rectories of Hadley and Monk's Ely, the archdeaconry of Suffolk, and a canonry of Canterbury. Among his principal publications we may reckon "Novum Testamentum Copticum," Oxon, 1716, 4to.; an edition of "Leges Saxonicae ecclesiasticae et civiles," with many valuable additions, 1721, fol.; "Joannis Seldeni Opera omnia," 1726, 3 vols. fol.; "Pentateuchus Copticus," 1731, 4to.; "Concilia Magnae Britanniae," 4 vols. fol. 1736; and a learned preface to bishop Tanner's "Britannico-Hibernica." He married the eldest daughter of Thomas, lord Fairfax, settled in Scotland, and died in 1745, in his 60th year. Nichols's Lit. Anecd. Gen. Biog.

WILKINS, JOHN, D.D., an English prelate, was born near Daventry, in Northamptonshire, in 1624, and finished his education at Magdalen-hall, Oxford, where he graduated M.A. He afterwards took orders, and became chaplain, first to lord Say, and then to Charles, count palatine of the Rhine. At the commencement of the civil war he joined the parliament, took the solemn league and covenant, and became warden of Wadham college. In 1649 he graduated D.D., and in 1656 married the sister of Oliver Cromwell. In 1659 he was nominated head of Trinity college, Cambridge; but being ejected on the restoration of king Charles II., he became preacher to the society of Gray's-Inn, London, and rector of St. Lawrence, Jewry; about which time he was introduced into the Royal Society as fellow and one of the council, and advanced to the see of Chester. He was distinguished by his moderation, and was reproached on this account by his enemies, who represented him as wavering in his religious principles. Several bishops censured him with uncandid severity, among whom were archbishop Sheldon, bishop Fell, and archbishop Dolben, making no allowance for the favourable disposition which he was led to manifest towards the dissenters by his education under Mr. John Dod, his grandfather, a truly pious and learned man, who disapproved many things in the church of England long before the grand separation which took place on account of Laud's impositions and severities. After the Restoration he was a moderate conformist, and disposed to be indulgent in many things, for the sake of preventing religious dissensions. On this account he incurred hatred and obloquy. He at length fell a victim to the stone, occasioned by his sedentary habits, and close application to study; and died, with a tranquillity and firmness becoming a wise man and a Christian, at the house of his friend Dr. Tillotson, in Chancery-lane, London, in November, 1672. Bishop Wilkins was not only an able divine, but a good mathematician and astronomer; and well skilled in mechanics and experimental philosophy. As a writer he was judicious and plain; and he studied more to be useful than to please. Generous in his disposition, he neither sought honour nor riches. The revenues which he received from the church he spent in its service; and whilst he was secure from want, he did not wish to be richer. His character is thus delineated by Dr. Burnet: "He was a man of as great a mind, as true a judgment, as eminent virtues, and of as good a soul, as any he ever knew; and though he married Cromwell's sister, yet he made no other use of that alliance but to do good offices, and to cover the university of Oxford from the frowns of Owen and Goodwin. At Cambridge he joined with those who studied to propagate better thoughts, to take men off from being in parties, or from narrow notions, from superstitious conceits, and fierceness about opinions. He was also a great observer and promoter of experimental philoso-

phy, which was then a new thing, and much looked after. He was naturally ambitious, but was the wisest clergyman I ever knew. He was a lover of mankind, and delighted in doing good." He also possessed, according to this historian, "a courage which could stand against a current, and against all the reproaches with which ill-natured clergymen studied to reproach him." His principal works are the following: viz. "The Discovery of a New World; or, a Discourse tending to prove that it is probable there may be another habitable World in the Moon," London, 1638, 4to., written when he was only twenty-four years of age; "Discourse concerning the Possibility of a Passage to the World in the Moon;" "Discourse concerning a new Planet, tending to prove that it is probable our Earth is one of the Planets," *ibid.* 1640, 8vo.; "Mercury; or, the Secret Messenger; shewing how a man may with privacy and speed communicate his thoughts to a friend at any distance," *ibid.* 1641, 8vo.; "Mathematical Magic; or, the Wonders that may be performed by Mechanical Geometry," in two books, *ibid.* 1648 and 1680, 8vo. These latter five, composing his mathematical works, were printed at London in one volume, 8vo. 1708. "Essay towards a real Character and a philosophical Language," *ibid.* 1668, fol.; "Of the Principles and Duties of Natural Religion," two books, *ibid.* 1675, 8vo. published by Dr. Tillotson. Also, "Sermons preached on several Occasions," and some others. Life prefixed to his Philosophical and Mathematical Works.

WILKINSON, in *Geography*, a county of Georgia, with 2154 inhabitants, including 318 slaves.—Also, a county of the Mississippi, with 5068 inhabitants, including 2630 slaves.

WILKOMIERS, a town of Lithuania, in the palatinate of Wilna, on the Swienta, near its union with the Wilna; 44 miles N.N.W. of Wilna.

WILKS, a county of North Carolina, with 9054 inhabitants.

WILKUSCHKE, a town of Prussia; 5 miles N.N.E. of Ragnitz.

WILL, VOLUNTAS, is usually defined a faculty of the mind, by which it embraces or rejects any thing represented to it, as good or evil, by the judgment.

Others will have it to be the mind itself, considered as embracing or refusing; adding, that as the understanding is nothing else but the soul, considered as *perceiving*; so the will is nothing else but the soul, considered as *willing*, &c.

Mr. Locke more intelligibly defines the will, a faculty which the soul has of beginning or forbearing, continuing or ending, several actions of the mind, and motions of the body, barely by a thought or preference of the mind, ordering, or as it were commanding, the doing, or not doing, such and such a particular action. This power which the mind has, to order the consideration of any idea, or the forbearing to consider it; or to prefer the motion of any part of the body to its rest, and *vice versa*, is what we call the will. See POWER.

The actual exercise of that power, is what we call *volition*, or willing; and the doing or forbearing of any action consequent on such order of the mind, is called *voluntary*. So far, according to this writer, as a man has a power to think or not to think, to move or not to move, according to the preference or direction of his own mind, so far he is free: and hence liberty, he says, is not an idea belonging to volition or preferring, but to the person having the power of doing, or forbearing to do, as the mind shall choose or direct. On the other hand, wherever any performance or forbearance is not equally in a man's power; wherever doing or not doing

will not equally follow upon the preference of his mind; there he is not free, though perhaps the action may be voluntary. Accordingly, where thought is wholly wanting, or the power to act or forbear according to the direction of thought, there necessity takes place; this, in an agent capable of volition, when the beginning or continuation of any action is contrary to the preference of his mind, is called *compulsion*: when the hindering or stopping of any action is contrary to his volition, it is called *restraint*. Agents that have no thought, no volition at all, are in every respect necessary agents.

Father Malebranche lays it down, that the will is that to the soul, which motion is to the body; and argues, that as the Author of nature is the universal cause of all the motions in matter, so he is of all the inclinations in the mind; and that as all motions are direct, unless their course be diverted and changed by some foreign cause; so all inclinations are right, and could have no other end but the enjoyment of truth and goodness, were there not some foreign cause to determine the natural impression to evil ends.

Accordingly, he defines will to be the impression, or natural motion, which carries us towards good indeterminately, and in the general; and the power the mind has, to direct this general impression towards any particular object that pleases it, is what he calls *liberty*.

Aristotle distinguishes two kinds of acts of the will, *viz.* βουλευσις, *willing, volition*; and προαιρεσις, *election*. The first, that employed about the ultimate end; the latter, about the means.

The schoolmen also distinguish the actions of the will into *elicit* and *commanded*. Elicit acts, *actiones elicite*, are those immediately produced by the will, and really inherent in it; such are *willing* and *nilling*. Commanded acts, *actiones imperate*, are effects produced by other powers; *v. gr.* the sensitive, intellectual, or locomotive powers, at the command or instigation of the will. As to *follow, stay, fight, fly, &c.*

But others will have the former kind properly to belong to the understanding; and only the latter to the will.

The word will is taken in three senses:

1. For the power or faculty of willing, in which sense it is, we have considered it above.
2. For the act or exercise of this power; as, when we say, No man wills his own destruction.
3. For a habit, or a constant disposition and inclination to do any thing. In which sense justice is defined a constant will to give every one what belongs to him: "Justitia est constans et perpetua voluntas jus suum unicuique tribuendi." Instit. Justin.

WILL, *Antecedent*. See ANTECEDENT.

WILL, *Free*. See LIBERTY, and FREEDOM.

WILL, *Last Will, or Testament, in Law*, a solemn act, or instrument, by which a person declares his mind and intention as to the disposal of his goods, effects, &c. after his death. See TESTAMENT.

This act or instrument is emphatically styled the will of the deceased, because it directs the disposal of the whole or part of his property, by written or oral instructions properly witnessed and authenticated, according to his pleasure. Some have distinguished between a testament and a will; a will being properly limited to land, and a testament only to chattels, requiring executors, which a will only for land doth not require: so that every testament is a will, but every will is not a testament. However, the words have been commonly used indifferently.

WILLS, *History of*. Wills or testaments, says judge Blackstone, are of very high antiquity. We find them

among the ancient Hebrews: not to mention what Eusebius and others have related of Noah's testament, made in writing, and witnessed under his seal, by which he disposed of the whole world, a more authentic instance of the early use of testaments occurs in the sacred writings (Gen. chap. xlviii.), in which Jacob bequeaths to his son Joseph a portion of his inheritance double to that of his brethren; which will we find executed many hundred years afterwards, when the posterity of Joseph were divided into two distinct tribes, those of Ephraim and Manasseh, and had two several inheritances assigned them; whereas the descendants of each of the other patriarchs formed only a single tribe, and had only one lot of inheritance. Solon was the first legislator that introduced wills into Athens; but in many other parts of Greece they were totally discountenanced. In Rome they were unknown, till the laws of the Twelve Tables were compiled, which first gave the right of bequeathing; and among the northern nations, particularly among the Germans, testaments were not received into use. Hence it appears, that the right of making wills and disposing of property after death, is merely a creature of the civil state, which has permitted it in some countries, and denied it in others, and subjected it to various restrictions and regulations, where the law allows it.

With us in England, this power of bequeathing is coeval with the first rudiments of the law; not indeed, that it extended originally to all a man's personal estate. See RATIONABILI parte bonorum.

It is also sufficiently clear, that, before the Conquest, lands were devisable by will. But, upon the introduction of the military tenures, the restraint of devising lands naturally took place, as a branch of the feudal doctrine of non-alienation without the consent of the lord. By the common law of England since the Conquest, no estate, greater than for term of years, could be disposed of by testament; except only in Kent, and in some ancient burghs, and a few particular manors, where their Saxon immunities by special indulgence subsisted. But when ecclesiastical ingenuity had invented the doctrine of *uses*, as a thing distinct from the land, uses began to be devised very frequently, and the devise of the use could in chancery compel its execution. However, when the statute of uses, *viz.* 27 Hen. VIII. cap. 10. had annexed the possession to the use, these uses, being now the very land itself, became no longer devisable: whereupon the statute of wills was made, *viz.* 32 Hen. VIII. cap. 1. explained by 34 & 35 Hen. VIII. cap. 5. which enacted, that all persons being seized in fee-simple (except feme-coverts, infants, idiots, and persons of nonsane memory) might by will and testament in writing devise to any other person, except to bodies corporate, two-thirds of their lands, tenements, and hereditaments, held in chivalry, and the whole of those held in focage; which now, through the alteration of tenures by the statute of Charles II. 12 Car. II. cap. 25. amounts to the whole of their landed property, except their copyhold tenements. As for copyhold and other customary lands, these are devisable or not, according to the custom of the respective manors. And generally, a devise of copyhold will not pass, without a surrender to the use of the will. In the case of a child or widow, a court of equity, in favour of these, will supply a defect of surrender (2 Vez. 582. 5 Vez. 557.); so also, when there is a general devise of real estate to pay debts, and there is no real estate but copyhold: also where a copyhold is in the hands of trustees, the person for whom the lands are holden in trust may devise the same without surrender. (2 Atk. 38. 1 Vez. 489.) And though the court will supply the defect of a surrender for the benefit of children, yet the rule

doth not extend to grand-children, or to a natural child, and consequently not to any more distant kindred. (2 *Ve.* 582. 1 *Wilson*, 161. 6 *Ve.* 544.) And if a man, seized of copyhold lands, surrenders the same to the use of his will, and executes a will, not attested by any witnesses, yet it shall direct the uses of the surrender: for the clause in the statute, which requires the testator's signing in the presence of three witnesses, is confined only to such estates as pass by the statute of wills of 34 & 35 Henry VIII., which doth not extend to copyhold. (2 *Atk.* 37. 7 *East's Rep.* 299.) See *MORTMAIN*.

By 29 Car. II. cap. 3. any estate *pur auter vie* shall be devisable by a will in writing, signed by the party so devising the same, or by some other person in his presence and by his express directions, attested and subscribed in the presence of the devisor by three or more witnesses; and if no such devise thereof be made, the same shall be chargeable in the hands of the heir, if it shall come to him by reason of a special occupancy, as assets by descent, as in case of lands in fee-simple; and in case there be no special occupant thereof, it shall go to the executors or administrators of the party that had the estate thereof by virtue of the grant, and shall be assets in their hands.

One that hath money to be paid him on a mortgage may devise this money when it comes. *God. O. L.* 391.

And if the feoffee in mortgage, before the day of payment which should be made to him, maketh his executors and die, and his heir entereth into the land as he ought; it seemeth in this case, that the feoffor ought to pay the money at the day appointed to the executors, and not to the heir of the feoffee: but yet the words of the condition may be such, as the payment shall be made to the heir; as if the condition were, that if the feoffor pay to the feoffee or to his heirs such a sum at such a day, there after the death of the feoffee, if he dieth before the day limited, the payment ought to be made to the heir at the day appointed. 1 *Inst.* 209, 210.

And hereby it appeareth, that the executors do more represent the person of the testator, than the heir doth that of the ancestor; for though the executor be not named, yet the law appoints him to receive the money, but so doth not the law appoint the heir to receive the money unless he be named. 1 *Inst.* 209, 210.

A person may devise by his will the right of presenting to the next avoidance, or the inheritance of an advowson. And if such devise be made by the incumbent of the church, the inheritance of the advowson being in him, it is good, though he die incumbent; for though the testament hath no effect but by the death of the testator, yet it hath an inception in his life-time: and so it is, though he appoint by his will who shall be presented by the executors, or that one executor shall present the other, or doth devise that his executors shall grant the advowson to such a man. *Watf. c.* 10.

But where an advowson was devised to the first or other son of B, that should be bred a clergyman and be in holy orders, and if B should have no such son, to C; both devises were holden by the court of common pleas to be void, as depending on too remote a contingency; for the rule of law is, that the contingency on which such an executory devise hinges must take effect within some life in being, or 21 years afterwards; but it was uncertain that the son of B, if he ever should have any, would take, or be able to take orders within 21 years of the death of his father. *Proctor v. the Bishop of Bath and Wells, and others*, 2 *H. Bla.* 358.

If upon articles for a purchase, the purchaser die, having

devised the land before a conveyance executed, the land will pass in equity; for the testator had an equity to recover the land, and the vendor stood trustee for the testator, and as he should appoint, till a conveyance executed. 1 *Chanc. Caf.* 39. 2 *Vern.* 679.

For the vendor of the estate is, from the time of his contract, considered as a trustee for the purchaser; and the vendee, as to the money, is considered as a trustee for the vendor. 1 *Atkyns*, 573.

So if a man covenants to lay out a sum of money in the purchase of lands, generally; and deviseth his real estate before he hath made such a purchase: the money to be laid out will pass to the devisee. *Id.*

But if a man, having made his will, afterwards contracts for the purchase of lands; the lands contracted for will not pass by the will, but descend to the heir at law. *Id.*

But if a good title cannot be made of the lands; as the heir in such case cannot have the lands, so he shall not have the money intended to be laid out. *Id.*

If a man have a lease for ever so many years, determinable upon life or lives, that is, if such or such live so long; this estate may well enough be given and disposed by will, because it is but a chattel. *Went.* 19.

A lease for years may also be devised to A for life, remainder to B. And if the lease be renewable, and A renew, B shall contribute to the fine so partaking of the benefit of the renewal.

If the testator, by his last will and testament, do give or bequeath to another any debt due unto him, or a thing in action belonging unto him, the legacy is good and effectual in the law, and may be recovered in this manner, that is to say, if the testator do make the legatary executor of that particular debt or thing in action bequeathed, then the legatary as executor thereof may commence suit in his own name, and recover the same to his own use, against him by whom it was due; but if the testator do not make the legatary executor of the debt or thing in action bequeathed, then his remedy lieth in the ecclesiastical court, where he may convent the executor, and compel him either to sue for that debt in a court competent, and upon recovery and payment thereof to pay it over to the legatary, or else to make a letter of attorney to the legatary for the recovery of the debt or thing in action bequeathed in the name of the executor to the use of the legatary. *Swin.* 187, 188.

Albeit the testator have no such thing of his own as is bequeathed, yet nevertheless the legacy is good in law; therefore, if the testator do bequeath a horse or a yoke of oxen, the legacy is good in law, though the testator have neither horse nor ox of his own. But who shall make choice, in this case, of the thing so bequeathed, is a question not to be neglected: and the solution is this; that if the words of the devise be directed to the legatary, as if the testator shall thus say, I will that A B shall have a horse, the choice doth belong to the legatary; but if the words be directed to the executor, as if the testator shall thus say, I will that my executor give to A B a horse, the election doth belong to the executor. Provided nevertheless, that to whomsoever the election doth belong, whether to the legatary, or to the executor, they must not be unreasonable in their election, but frame themselves according to the meaning of the testator; otherwise the legatary might make choice of the best horse in the country, and the executor of the worst, contrary to the meaning of the deceased. *Swin.* 188.

If there be two joint-tenants of lands, and one of them deviseth that which to him belongs, and dieth; this is no good devise, and the devisee takes nothing, because the devisee

WILL.

will doth not take effect until after the death of the devisor, and then the surviving joint-tenant takes the whole by prior title, to wit, from the first feoffment. Gilbert on Wills, 120.

And although the jointure is severed before the testator's death, yet if the will be made before the severance, it will have no effect; unless there is a republication of the will after the partition. Bur. Mansf. 1496.

So also a man cannot give or bequeath by will any of those goods or chattels which he hath jointly with another: for if he should bequeath his portion thereof to a third person, this bequest is void by the laws of this realm; and the survivor, which had those goods or chattels jointly with another, shall have that portion so bequeathed, notwithstanding the said will. Swin. 189.

But otherwise it is with the tenants in common (God. O. L. 131.) and coparceners. For there is no survivor between coparceners, but the part of each is descendible, and consequently may be devised. (Co. Lit. 185. b.) And a deed of partition is not a revocation of a devise of his moiety by tenant in common. Luther v. Ridley, cited in 3 P. Wms. 169.

By 20 Hen. III. cap. 2. widows may bequeath the crop of their ground, as well of their dowers, as other their lands and tenements; saving to the lords of the fee all such services as be due for their dowers and other tenements. And this is only in affirmance of the common law. (2 Inst. 80.) But by 27 Hen. VIII. cap. 10. a married woman, having a jointure made, shall not have any dowry of the residue of her husband's lands.

By 28 Hen. VIII. cap. 11. if the incumbent before his death hath caused any of his glebe land to be manured and sown, at his proper costs and charges, with any corn or grain; he may make and declare his testament of all the profits of the corn growing upon the said glebe land so manured and sown.

But if the testator is lessee for years, and sows the land a short time before his lease expires, and then dies, before the corn can possibly be ripe within the term, in this case a devise thereof is void, because he himself could not have reaped it after the expiration of the term, if he had lived. Swin. 191.

Not only that thing may be devised or bequeathed by the testator, which is truly extant, or hath an apparent being at the time of the making of the will or death of the testator; but that thing also which is not in *rerum natura*, whilst the testator liveth: therefore, it is lawful for the testator to bequeath the corn which will be sown or grow in such soil after his death, or the lambs which shall come of his flock of sheep the next year, depasturing in such a field. But if there be no such corn growing in that soil, nor any lambs arising out of that flock, then the legacy is destitute of effect; because no such thing is extant at all as was bequeathed. But if the testator devise a certain quantity of grain or number of lambs, as for the purpose, twenty quarters of corn or twenty lambs, and doth will and devise, that the same shall be paid out of the corn which shall grow in such a field, or arise out of his sheep depasturing in such a ground; though not so much or no corn at all there grow, or not any or not so many lambs there arise, yet nevertheless the executor is compellable by law to pay the whole legacies entirely; because the mention of the soil and of the flock was rather by way of demonstration than by way of condition, rather shewing how or by what means the said legacy might be paid, than whether it should be paid at all yea or no. Swin. 186.

Those things which after the death of the testator descend

to the heir of the deceased, and not to his executor, cannot be devised by testament, except in such cases wherein it is lawful to devise the lands, tenements, or hereditaments.

If a man be seized of a house, and possessed of divers heir-looms, that by custom have gone with the house from heir to heir, and by his will deviseth away these heir-looms; this devise is void: for the will taketh effect after his death; and by his death, the heir-looms by ancient custom are vested in the heir, and the law prefers the custom before the devise. And so it is, if the lord ought to have a heriot against his tenant, and the tenant deviseth away all his goods; yet the lord shall have his heriot for the reason aforesaid. 1 Inst. 185.

The testator may devise all goods and chattels which he hath in his own right, but not those which he hath in the right of another as executor. Swin. 185.

An administrator cannot make a testament of those goods which he hath as administrator to any person dying intestate; because he hath not any such goods to his own proper use, but ought therewithal to pay the debts of the dead person, and to distribute the rest according to law. Swin. 189.

The husband cannot devise such goods as his wife hath as being executrix to another, nor such things as are in action, as debts due to her before marriage by obligation or contract, unless he and his wife recover the same during marriage, or that he renew the bonds, and take them in his own name; otherwise after his death they remain to her. 1 Inst. 351.

But the husband may, at any time during the coverture, release a bond given to his wife. And where the husband makes a settlement, the bonds to his wife, being part of her fortune, will notwithstanding his death in the life-time of his wife, before the security be changed, be decreed in equity to his executor; he being considered in that case as a purchaser for a valuable consideration. Cases in the time of L. Talb. 168.

A man may by his will dispose of his chattels and personal estate that he shall for the future acquire, any time after the making his will, to the time of his death. And this is necessary from the reason of the thing; because the chattels and personal estate are in a continual fluctuation; and if the law were not so, it would create very great confusion, or else would render it necessary for a man to make a new will every day. Gilb. 122.

But it is not so with lands, for they are fixed and permanent: and, therefore, if a man maketh his will, and deviseth therein all the lands which he shall have at the time of his death; and after that, he purchaseth lands, and dieth without republication or making a new will; in this case, though his intent to the contrary is very apparent, yet it is a void devise: for a man cannot devise any lands but what he hath at the time of making his will. And this was adjudged upon great deliberation, by Holt chief justice and the court, in the case of Bunker and Cook: and the judgment was affirmed afterwards upon a writ of error in the house of lords, Feb. 24, 1707. Gilb. 122.

But, by Holt chief justice: If he republished his will, in such manner, and with such circumstances, as are necessary to complete execution of an original will; then the purchased lands will pass as by an original will. (11 Mod. 127.) And in truth this seemeth to make it a new will, to all intents and purposes; and not a republication of the old one.

But a codicil, which concerneth only personal legacies, will not amount to a republication of the will, so as to pass lands purchased after the making of the will. 2 Vern. 625.

If a man deviseth all his lands for payment of his debts, and purchaseth lands afterwards: the lord keeper said he would decree a sale, though there were no precedent articles. 2 Cha. Ca. 144.

If a man hath a lease, and disposeth of it specifically by his will; and after surrenders it and takes a new lease, and after dies; the devisee shall not have this last lease, because this was a plain countermand of his will. Goldf. 93.

But in the case of Stirling and Lydiard, Nov. 21, 1744, where a man devised all and singular his leasehold estate, goods, chattels, and personal estate whatsoever, and afterwards renewed a lease; it was held by the lord chancellor Hardwicke clearly, that the leasehold estate passed by the will.

If a man deviseth a term for years, which he hath not at the time of the devise, but purchaseth some time before his death; Holt chief justice doubted whether this would be good. But Mr. Peere Williams says, that notwithstanding the doubt which the court of king's bench seems to have had in that case, it hath been clearly held to pass by such a will. 3 P. Wms. 169.

WILLS, Persons capable of making. Every person hath full power and liberty to make a will, that is not under some special prohibition by law or custom: which prohibitions are principally upon three accounts; for want of sufficient discretion; for want of sufficient liberty and free will; and on account of criminal conduct.

In the first class are to be reckoned infants, under the age of fourteen if males, and twelve if females; which is the rule of the civil law. By statute 34 & 35 Hen. VIII. cap. 5. wills or testaments made of any manors, lands, tenements, or other hereditaments, by any person within the age of twenty-one years, shall not be taken to be good or effectual in law; for until that time, by the common laws of this realm, they are accounted infants. (Swinb. 74.) But by custom in particular places, they may devise lands before the age of twenty-one. (God. O. L. 21. Wentw. 24.) But no custom of any place can be good, to enable a male infant to make any will before he is fourteen years of age. (Law of Exec. 153.) If the testator is not of sufficient discretion, whatever be his age, that will overthrow his testament. Accordingly, madmen, or otherwise *non compos*, idiots or natural fools, persons grown childish by age or distemper, such as have their senses befuddled with drunkenness; all these are incapable, by reason of mental disability, to make any will as long as such disability lasts. To this class may also be referred such persons as are born deaf, blind, and dumb; who, as they have always wanted the common inlets of understanding, are incapable of having *animum testandi*, and their testaments are therefore void. It has been maintained that persons deaf and dumb, who understand what a testament meaneth, and that are desirous of making one, may by signs and tokens declare their testament: and that a blind person may make a nuncupative testament, by declaring his will before a sufficient number of witnesses; and that he may make his testament in writing, provided the same be read before witnesses, and in their presence acknowledged by the testator for his last will. Swinb. 95, 96.

Persons of the second description are by the civil law of various kinds; as prisoners, captives, and the like. But the law of England does not make such persons absolutely intestable; but only leaves it to the discretion of the court to judge, upon the consideration of their peculiar circumstances of duress, whether they could be supposed to have *liberum animum testandi*. With regard to feme-coverts, our laws differ still more materially from the civil. Among the

Romans, a married woman was as capable of bequeathing as a feme-sole. But with us, a married woman is not only utterly incapable of devising lands, being excepted out of the statute of wills, 34 & 35 Hen. VIII. cap. 5. but also she is incapable of making a testament of chattels, without the licence of her husband, who frequently, upon marriage, covenants with her friends to allow her that licence: his assent, therefore, must be given to the particular will in question, without which it will not be a complete testament. Her will, therefore, operates in the nature of an appointment, the execution of which the husband by his bond, agreement, or covenant, is bound to allow. The queen-consort is an exception, for she may dispose of her chattels by will, without the consent of her lord: and any feme-covert may make her will of goods, which were in her possession *in auter droit*, as executrix or administratrix; for these can never be the property of her husband: and if she has any pin-money or separate maintenance, it is said she may dispose of her savings thereof by testament, without the controul of her husband. But if a feme-sole makes her will, and afterwards marries, such subsequent marriage is esteemed a revocation in law, and entirely vacates the will.

Persons of the third class are, first, all traitors and felons, from the time of conviction; for then their goods and chattels, and all such lands, tenements, and hereditaments, as they shall have in their own right, use, or possession, of any estate or inheritance, at the time of such treason committed, or at any time after, are forfeited to the king. The testament before made doth, by reason of the same conviction, become void both in respect of goods, and also in respect of lands, tenements, and hereditaments. But if a person, attainted of treason, obtain the king's pardon, and be thus restored to his former estate, he may make his testament, and his former testament is good. (Swinb. 97.) Neither can a *felo de se* make a will of goods and chattels, for they are forfeited by the act and manner of his death; but he may make a devise of his lands, for they are not subjected to any forfeiture. (3 Inst. 55.) Outlaws also, though only for debt, are incapable of making a will, so long as the outlawry subsists, for during that time their goods and chattels are forfeited; but he that is outlawed in an action personal, may make his testament of lands, for they are not forfeited. (Swinb. 107.) An outlaw in a personal action may in some case make executors; for he may have debts upon contract, which are not forfeited to the king; and those executors may have a writ of error to reverse the outlawry. (Cro. Eliz. 851.) Coke observes, that an excommunication (meaning the greater excommunication) is worse than an outlawry; for if a plaintiff, who is an executor, be outlawed, his outlawry cannot be pleaded to disable him from proceeding in the suit, because it is in the right of another; but if he is excommunicated, it is otherwise, because every man that converses with such a person is excommunicated himself (1 Inst. 134.); that is, after he is denounced excommunicate, and they are admonished not to converse with him. (Ayl. Par. 266.) As for persons guilty of other crimes, short of felony, who are by the civil law precluded from making testaments, (as usurers, libellers, and others of a worse stamp,) by the common law their testaments may be good.

WILL, Nature and Incidents of a. Wills or testaments are divided into two sorts, *viz.* *written* and *verbal* or *nuncupative*: of which the former is committed to writing; the latter depends merely upon oral evidence, being declared by the testator *in extremis* before a sufficient number of witnesses, and afterwards reduced to writing. A codicil is a supplement to a will.

As *nuncupative* wills and codicils are liable to great impositions, and may occasion many perjuries, the statute of frauds, 29 Car. II. cap. 3. hath laid them under many restrictions; except when made by mariners at sea, and soldiers in actual service. As to all other persons, it enacts, 1. That no written will shall be revoked or altered by a subsequent *nuncupative* one, except the same be in the life-time of the testator reduced to writing, and read over to him and approved; and unless the same be proved to have been so done by the oaths of three witnesses at least; who, by 4 & 5 Ann. cap. 16. must be such as are admissible upon trials at common law.

2. That no *nuncupative* will shall be good, where the estate bequeathed exceeds 30*l.*, unless proved by three such witnesses, present at the making of it, and unless they or some of them were specially required to bear witness to it by the testator; and unless it was made in his last sickness, in his own habitation, or where he had previously resided at least ten days, except he be surpris'd with sickness on a journey, or from home, and dies without returning to his dwelling.

3. That no *nuncupative* will shall be proved by the witnesses after six months from the making, unless it were put in writing within six days; nor shall it be proved till fourteen days after the death of the testator, nor till process hath first issued to call in the widow, or next of kin, to contest if they think proper.

As to *written* wills (*viz.* those that concern not the devise of lands), they need not any witness of their publication. A testament of chattels, written in the testator's own hand, though it has neither his name nor seal to it, nor witnesses present at its publication, is good; provided sufficient proof can be had that it is his hand-writing. (Swinb. 353. Gilb. Rep. 260.) And though written in another man's hand, and never signed by the testator, yet if proved to be according to his instructions, and approved by him, it hath been held a good testament of the personal estate. However, it is the safer and more prudent way, and leaves less in the breast of the ecclesiastical judge, if it be signed or sealed by the testator, and published in the presence of witnesses. It is said in 3 Salk. 396. that by the canon law, and also by the common law, two witnesses are requisite to prove a will of goods; for one witness by the civil law, unto which the other laws are conformed in this matter, is as no witness at all. 1 P. Wms. 13.

The statute of frauds and perjuries, 29 Car. II. cap. 3. directs, that all devises of lands and tenements shall not only be in writing, but signed by the testator, or some other person in his presence, and by his express direction; and be subscribed, in his presence, by three or four credible witnesses. In the construction of this statute, it has been adjudged that the testator's name, written with his own hand at the beginning of his will, as, "I John Mills do make this my last will," &c. is a sufficient signing, without any name at the bottom; though the other is the safer way. (3 Lev. 1.) It hath been said, that if the testator only put his seal to the will, without signing it, this is a sufficient signing within the statute; because signing is no more than a mark to distinguish a man's act, and sealing is a sufficient mark to know it to be his will. (Gilb. 93.) Others, however, have held that sealing without signing was not sufficient. (1 Wilson, 313. 2 Vezey, 459.) Signing being only mentioned in the statute, sealing is not necessary. (God. O. L. 5. 1 Wentw. 29.) It has also been determined, that though the witnesses must all see the testator sign, or at least acknowledge the signing, yet they may do it at different times. But they must all subscribe their

names as witnesses in his presence, lest by any possibility they should mistake the instrument. In one case determined by the court of king's bench, the judges would not allow any legatee, nor consequently a creditor, where the legacies and debts were charged on the real estate, to be a competent witness to the devise. This determination occasioned the statute 25 Geo. II. cap. 6. which restored both the competency and credit of such legatees, by declaring void all legacies given to witnesses, and thereby removing all possibility of their interest affecting their testimony. The same statute likewise established the competency of creditors, by directing their testimony to be admitted; but leaving their credit (like that of all other witnesses) to be considered, on a view of all the circumstances, by the court and jury before whom such will shall be contested. And in a much later case, M. 31 Geo. II. the testimony of three witnesses, who were creditors, was held to be sufficiently credible, though the land was charged with the payment of debts. By stat. 29 Car. II. cap. 3. all declarations or creations of trusts or confidences, of any lands, tenements, or hereditaments, shall be manifested and proved by some writing signed by the party who is by law enabled to declare such trust, or by his last will in writing, or else they shall be utterly void, and of none effect. And all grants and assignments of any trust or confidence shall likewise be in writing, signed by the party granting or assigning the same by such last will or devise; or else shall be utterly void, and of none effect.

No testament is of any effect till after the death of the testator; and, therefore, if there be many testaments, the last overthrows all the former; but the republication of a former will revokes one of a later date, and establishes the first again. Although no man can die with two testaments, because the latter doth always infringe the former; yet a man may die with divers codicils, and the latter doth not hinder the former, so long as they be not contrary. (Swinb. 15.) All codicils are part of the will; therefore, a codicil merely for a particular purpose, as to change an executor, and confirming the will in all other respects, does not revive a part of the will revoked by a former codicil. If two testaments be found, and it doth not appear which was the former or latter, both testaments are void; but if two codicils be found, and it cannot be known which was the first or last, and one and the same thing is given to one person in one codicil, and to another person in another codicil, the codicils are not void, but the persons therein named ought to divide the thing betwixt them. Swinb. 15.

If codicils are regularly executed and attested, they may be proved as wills are. So if they are found written by the testator himself, they ought to be taken as part of the will, and to be proved in common form by the oath of the administrator with the will annexed; and in case of opposition, by witnesses to the hand-writing and finding; and it hath been usual to exhibit an affidavit of the hand-writing and finding, before a probate or administration passes even in common form.

But in case of a real estate, a codicil cannot operate, unless it be executed according to the statute. 1 Ark. 426.

By stat. 29 Car. II. cap. 3. no devise in writing of lands, tenements, or hereditaments, or any clause thereof, shall be revocable, otherwise than by some other will or codicil in writing, or other writing declaring the same, or by burning, cancelling, tearing, or obliterating the same by the testator himself, or in his presence, and by his directions and consent; but all devises and bequests of lands and tenements shall remain and continue in force, until the same be burnt, cancelled, torn, or obliterated by the testator, or by his direc-
tions

tions in manner aforesaid, or unless the same be altered by some other will or codicil in writing, or other writing of the deviser, signed in the presence of three or four witnesses declaring the same.

And no will in writing concerning any goods or chattels or personal estate shall be repealed, nor shall any clause, devise, or bequest therein be altered or changed, by any words, or will by word of mouth only, except the same be in the life of the testator committed to writing, and after the writing thereof read unto the testator, and allowed by him, and proved to be so done by three witnesses at the least.

A will which will pass personal estate is not a sufficient revocation of a former will, by which a real estate is devised. Comyns, 451.

Although the statute says, that no will in writing concerning personal estates shall be repealed by word of mouth only, except the words be put into writing, and read to and allowed by the testator, and proved to be so done by three witnesses; yet where a man by will in writing devised the residue of his personal estate to his wife, and she dying, he afterwards by a nuncupative codicil bequeathed to another all that he had given to his wife, this was resolved to be good: for by the death of the wife, the devise of the residue was totally void; and the codicil was no alteration of the former will, but a new will for the residue. 1 Abr. Caf. Eq. 408.

Also, the statute hath not taken away revocations of wills by act of law; as if the testator afterwards make a feoffment, or do any other act inconsistent with the will: but such revocation remains as before the statute. Carth. 81.

If a man devises lands to one and his heirs, and afterwards mortgages the same lands to another for years or in fee; though a mortgage in fee is a total revocation at law, yet in equity it shall be a revocation *pro tanto* only. 1 Abr. Eq. Caf. 410.

And the reason is, because a mortgage is not considered as a conveyance of the estate, but only as a charge upon it; being merely a security, and in the consideration of equity carries only a chattel interest, the creditor gains nothing real, it affords no dower, and goes to executors. Sparrow and Hardcastle, May 6, 1754. 3 Atk. 798.

But if lands be devised to one in fee, and afterwards mortgaged to the same devisee; this is a revocation *in toto*, being inconsistent with the devise: but if the mortgage had been to a stranger; it had been a revocation *quoad* the mortgage only. Prec. Cha. 514.

If a man seised in fee devises it to one in fee or for life, and afterwards makes a lease to another for years; this, even at law, shall not be a revocation but during the years. 1 Roll's Abr. 616.

So if a husband possessed for forty years devises it to his wife, and after leases the land to another for twenty years, and dies; this lease is not any revocation of the whole estate, but only during the twenty years, and the wife shall have the residue by the devise. Id.

But where a man seised of a lease for lives devised it, and afterward surrendered the old lease, and took a new one to him and his heirs for three lives; it was decreed, that this renewal of the lease was a revocation of the will as to this particular. For by the surrender of the old lease, the testator had put all out of him, had divested himself of the whole interest; so that there being nothing left for the devise to work upon, the will must fall, and the new purchase, being of a freehold descendible, could not pass by a will made before such purchase. 3 P. Wms. 166. 170.

But where the testator devised all and singular his leasehold estate, and afterwards renewed a lease; it was held by

lord Hardwicke clearly, that this leasehold estate passed by the will: for that this is not a specific legacy, but only an enumeration of the several particulars of the personal estate, but yet is a general devise of the whole. 3 Atk. 199.

Though a covenant or articles do not at law revoke a will; yet if entered into for a valuable consideration, amounting in equity to a conveyance, they must consequently be an equitable revocation of a will, or of any writing in nature thereof. 2 P. Wms. 624.

A woman's marriage is alone a revocation of her will. Id.

A man made a will, and appointed one (who was no relation) to be his executor. He afterwards went abroad, where he became a governor of one of the plantations, and sent over for an English woman of his acquaintance, whom he married, and had children by; and died, without an actual revocation of his will. Yet it was determined, that this total alteration of his circumstances was an implied revocation. 1 P. Wms. 304.

It is an established maxim, that wills should be construed favourably. Accordingly, the intention of the testator is called by lord Coke the polar-star, to guide the judges in the exposition of wills. In divers instances, relating to the interpretation of wills, collateral evidence hath been admitted in the court of chancery to explain the testator's intention. But notwithstanding these cases, the courts have been very unwilling to admit of parol evidence in relation to any thing that appears on the face of a will; and it is certain that too much caution cannot well be used in this particular, especially when it is considered that the statute of frauds and perjuries, which was made to prevent perjury, contrariety of evidence, and uncertainty, binds the courts of equity as well as the common-law courts; as also that little regard ought in many cases to be had to the expressions of the testator, either before or after the making his will, because possibly these expressions might be used by him, on purpose to conceal or disguise what he was doing, or to keep the family quiet, or for other secret motives and inducements which cannot after his death be found out. 2 Bac. Abr. 310.

Notwithstanding that wills are generally favoured by the law; yet where the testator endeavours to establish a settlement against the reason and policy of the common law, the judges will reject it. Gilb. 110. 2 Bac. Abr. 79.

Also where the testator by his will maketh no other disposition of his estate than the law itself would have done, had he been silent; there such a will is useless, and shall be rejected: and, therefore, if a devise be made to a person and his heirs, which person is heir at law to the deviser; this is a void devise, and the heir shall take by descent as his better title; for the descent strengthens his title, by taking away the entry of such as may possibly have right to the estate; whereas if he claims by devise, he is in as by purchase. Gilb. 110. 2 Bac. Abr. 79.

Also devises are void and rejected, where the words of the will are so general and uncertain, that the testator's meaning cannot be collected from them; and, therefore, where a man by will gave *all* to his mother, the general words did carry no *lands* to his mother; for since the heir at law hath a plain and uncontroverted title, unless the ancestor disinherits him, it would be severe and unreasonable to set him aside, unless such intention of the testator is evident from the will; for that were to set up and prefer a dark and at best but a doubtful title to a clear and certain one. Gilb. 112. 2 Bac. Abr. 81.

The clause of "perfect mind and memory" is more usual than necessary in a will, and yet not hurtful. (Swinb. 7.)

WILL.

But in case of contell, it is necessary to prove the sanity of the testator. 2 Atk. 56.

For the different modes of devise, and the legal meaning of the appropriate terms by which they are expressed, we refer to Burn's Ecclesiastical Law, *ubi infra*.

From the above accounts it follows, that testaments may be avoided three ways: 1. If made by a person labouring under any of the incapacities before mentioned. 2. By making another testament of a later date. And, 3. By cancelling or revoking it.

The Romans were wont to set aside testaments, as being *inofficiosa*, deficient in natural duty, if they disinherited or totally passed by (without assigning a true and sufficient reason) any of the children of the testator. But if the child had any legacy, though ever so small, it was a proof that the testator had not lost his memory nor his reason, which otherwise the law presumed. Hence probably, says Blackstone, has arisen that groundless vulgar error of the necessity of leaving the heir a shilling or some other express legacy, in order to effectually disinherit him; whereas the law of England, though the heir or next of kin be totally omitted, admits no *querela inofficiosa*, to set aside such testament. Burn's Eccl. Law, vol. iv. art. WILL. Blackst. Com. book ii.

WILLS of Seamen and Marines. By the statute 26 Geo. III. c. 63. no will made by any petty officer or seaman in the king's service, whereby any wages, pay, prize-money, or allowance of money of any kind due for such service is bequeathed, shall be valid, unless, if made while the party is in the service, it be signed before and attested by the captain, or the officer then commanding, and one of the signing officers of the ship to which the party belongs, and unless it specify in the body thereof the name of the ship, and the number at which the maker of the will stands upon the ship's books, and contains a full description of the residence, profession, or business of the person in whose favour it is made, and the day of the month and the place where it was executed, or by the agent of any of his majesty's hospitals or quarters appointed to receive sick and wounded seamen, in which the party may be at the time; or if made by such officer or seaman discharged from the service, within the bills of mortality, unless it be attested by the officer appointed by the treasurer of the navy to inspect such wills; or if made at any of the ports where seamen's wages are paid, unless it be attested by the treasurer of the navy, chief or second clerk there; or if made at any other place, unless it be attested by the minister and churchwardens of the parish in England or Ireland, or by two elders of the parish in Scotland. In order to obtain a probate thereof, the will must be sent to a proctor by the inspector of wills appointed by the treasurer of the navy.

If any such petty officer or seaman should die intestate, the person claiming administration must apply by petition to the said inspector, who is to grant a certificate directed to a proctor, that letters of administration may pass in favour of the petitioner, if entitled thereto by law.

If any proctor, register, or other officer of any ecclesiastical court shall be aiding and assisting in procuring probate of a will, or letters of administration, for the purpose of enabling any person to receive such wages, pay, prize-money, or allowance of money of any kind, without first obtaining the certificate from the inspector of seamen's wills, or person authorized to officiate for him, every such proctor, register, or other officer, shall forfeit 500*l.*, and for ever after be incapable of acting in any capacity in any ecclesiastical court in Great Britain or Ireland.

And by the 32 Geo. III. c. 34. after the 1st day of Au-

gust 1792, no letter of attorney or will of a non-commissioned officer of marines or marine shall be valid unless made according to the 26 Geo. III. c. 63.

All are to be deemed petty officers, seamen, marines, &c. except such as are rated upon the books of such ship, admirals or flag officers, and their secretaries, captains, and lieutenants, masters, second masters, and pilots, physicians, surgeons, chaplains, boatswains, gunners, carpenters, and purifiers, captains of marines, captain lieutenants of marines, lieutenants, and quarter-masters of marines.

Every lieutenant, on board any of his majesty's ships, shall upon a page of every muster book of such ship sign his name for the purpose, and for the purpose only, that the inspector of seamen's wills, or such person as shall be deputed by him, may have an opportunity of comparing the same with the name of any such lieutenant attesting the will, &c. executed by or in favour of any petty officer, seaman, non-commissioned officer of marines or marine.

And all captains of ships shall, upon their monthly muster books or returns, specify which of the men, mentioned in the said returns, have granted or issued any will or testament during that month or space of time from the preceding returns, by inserting the date thereof opposite to the party's name. The muster books, &c. in case of sailing from any foreign station, at a time when no opportunity shall offer of transmitting them to the navy-board, to be left with the naval officer of the place, if any, or with some respectable merchant, with directions to forward the same to the commissioners of his majesty's navy by the first safe opportunity, and in case of the removal of the commander, to be delivered over to his successor and a receipt given for the same.

Provided that it shall be lawful for the minister of any parish, to whom the inspector of seamen's wills shall transmit his check of any letter of attorney or will, passed and allowed by him, to deliver the said check to the attorney or executor in the said letter of attorney or will named and appointed. And all seamen's letters of attorney, and wills made prior to the 1st of August 1786, and those of marines prior to the 1st of August 1792, shall be examined and inspected by the inspector of seamen's wills for the purpose of preventing frauds, forgeries, or impositions of any kind therein; and if such inspector shall see no cause to suspect the authenticity of the same, he shall affix the stamp of his office, and issue checks for the same, but if he shall see good cause to suspect the truth and authenticity of such letter of attorney or will, he shall report the same to the treasurer, or to the paymaster of the navy, and shall enter his caveat against such letter of attorney or will, which shall prevent any money from being paid or received thereon until the same shall be authenticated to the satisfaction of the said treasurer or paymaster.

The wages, pay, prize-money, or allowances of petty officers or seamen, non-commissioned officers of marines, and marines dying intestate, are to be paid only upon letters of administration obtained in the following manner:

The person claiming such administration shall send or give in a note or letter to the inspector of seamen's wills, stating the name of the deceased, the name of the ship or ships to which he belonged, and that he has heard or been informed of his death, and requesting the inspector to give such directions as may enable him to procure letters of administration to the deceased, or to the like effect, upon receipt whereof the inspector of seamen's wills shall deliver or send to the person claiming such administration, a paper in a peculiar form of words, which paper being duly filled up and certified shall be returned to the treasurer, or to the paymaster of his majesty's navy, London, who upon receiving

the same shall direct the inspector of seamen's wills to examine the same, and make such inquiry relative thereto as may appear to him necessary on that behalf; and being satisfied, he shall forthwith make out a certificate for obtaining letters of administration, and pursue the course minutely described in Burn's Ecclesiastical Law, art. *Wills*.

By 32 Geo. III. c. 34. the following sums are to be paid for the seal, parchment, writing, and suing forth of probates of wills and letters of administration granted in pursuance of this act, for the purpose of receiving wages, or pay, or allowances of money of any kind, which shall remain due to the deceased, *viz.*

	£.	s.	d.
For probates of wills, if the goods and chattels are under the value of 20 <i>l.</i> - - - - -	0	15	2
For letters of administration - - - - -	1	4	2
For probates of wills under 40 <i>l.</i> - - - - -	1	8	8
For administration - - - - -	1	17	8
For probates of wills under 60 <i>l.</i> - - - - -	1	11	2
For administration - - - - -	2	8	6
For probates of wills under 100 <i>l.</i> - - - - -	1	13	8
For administration - - - - -	2	11	0
For commissions or requisitions to swear executors or administrators:			
Under 20 <i>l.</i> - - - - -	0	15	0
And under 100 <i>l.</i> - - - - -	1	3	0

But if the probates or letters of administration be granted to the widow, children, father, mother, brother, or sister, in pursuance of this act, for the same purpose of receiving wages, or pay, or allowances of money of any kind, which shall remain due to such warrant or petty officer, &c. then the following sums are to be paid, *viz.*

	£.	s.	d.
For probates of wills under 20 <i>l.</i> - - - - -	0	6	0
For administration - - - - -	0	14	0
For probates of wills under 40 <i>l.</i> - - - - -	0	19	6
For administration - - - - -	1	7	6
For probates of wills under 60 <i>l.</i> - - - - -	1	3	0
For administration - - - - -	1	11	0
For probates of wills under 100 <i>l.</i> - - - - -	1	7	6
For administration - - - - -	1	15	6
For commissions or requisitions to swear executors or administrators:			
Under 20 <i>l.</i> - - - - -	0	12	0
Under 40 <i>l.</i> - - - - -	0	15	6
Under 60 <i>l.</i> - - - - -	0	16	6
Under 100 <i>l.</i> - - - - -	0	18	6

And no more than 5*s.* are to be taken for the suing forth of the probate of any will or letters of administration granted to the widow, children, father, mother, brother, or sister of any such seaman or marine, &c. and 5*s.* for commissions or requisitions to swear such widow, &c. unless the goods amount to 100*l.*: which last-mentioned charge of 5*s.* must be understood to be demandable where the probate or letters of administration are not for the purpose of receiving wages, or pay, or allowances of money remaining due, but for general purposes, as to obtain administration of the goods and chattels of the deceased.

A bill of the expences of obtaining letters of administration to creditors, is to be laid before and taxed by one of the registers of the prerogative court of Canterbury, or their deputies, who are entitled to a fee of 3*s.* 4*d.* for the same; and the proctor is to transmit such letters of administration with the bill of expences so certified, to the treasurer or paymaster of his majesty's navy. Proctors taking more than the prescribed sums forfeit 50*l.*, and registers and

other officers of any ecclesiastical court, procuring letters of administration or probate contrary to this act and the 26 Geo. III., to be incapacitated to act, and forfeit 50*l.*

WILL, Qualification and Office of the Executor of a. See EXECUTOR, EXECUTOR *de son Tort*, and JOINT-Executors. See also DEBTS, DEBTEE-Executor, INVENTORY, and LEGACY.

WILL, Probate of a. See PROBATE.

WILL, Estate at, in Law, is where lands and tenements are let by one man to another, to have and to hold at the will of the lessor; and the tenant by force of this lease obtains possession. Every estate of this kind is at the will of both parties, landlord and tenant: so that either of them may determine his will, and quit his connection with the other at his own pleasure, under certain restrictions. For, if the tenant at will sows his land, and the landlord, before the corn is ripe, or reaped, puts him out, the tenant shall have the emblements, and free ingress and egress to cut and carry away the profits. But where the tenant himself determines the will, the landlord shall have the profits of the land. The law is careful, that no such sudden determination of the will by one party shall tend to the manifest and unforeseen prejudice of the other. This appears in the case of emblements just mentioned; and also, the lessee after the determination of the lessor's will shall have reasonable ingress and egress to fetch away his goods and utensils. And if rent be payable quarterly or half-yearly, and the lessee determines the will, the rent shall be paid to the end of the current quarter or half-year. Upon the same principle, courts of law have of late years inclined as much as possible against construing demises, where no certain term is mentioned, to be tenancies at will: but have rather held them to be tenancies from year to year, so long as both parties please, especially where an annual rent is reserved: in which case they will not suffer either party to determine the tenancy even at the end of the year, without reasonable notice to the other. Blackst. Com. vol. ii.

WILL with a Whisp. See IGNIS Fatuus.

WILL'S Cove, in Geography, a creek on the N.E. coast of the island of St. Christopher, to the S.W. of Muddy Point.

WILL'S Creek, a river of Maryland, which runs into the Potomack, N. lat. 39° 30'. W. long. 78° 47'.

WILLACH. See VILLACH.

WILLAERT, ADRIAN, in Biography, the disciple of John Mouton, and master of Zarlino, has been long placed at the head of the Venetian school of counterpoint by the Italians themselves. He was born at Bruges in Flanders, and during his youth studied the law at Paris; if with the view of making it his profession, there must have been an early conflict between legislation and music, which having a powerful advocate in his own heart gained the cause; for by his own account (see JOSQUIN) he went to Rome in the time of Leo X., where he found that his motet, "Verbum bonum et suave," was performed in the pontifical chapel, as the work of that renowned composer; he therefore must have been a contrapuntist some time, before any of his works could have travelled to Rome.

The account which Zarlino gives of this motet (P. i. p. 175.) having passed for a work of Josquin, excited our curiosity to see it; and finding it among the Motetti della Corona, in the British Museum, we scored it; but discovered that the predilection for a great name had operated too powerfully in favour of this composition while Josquin was imagined to be the author of it; for it is neither written with the clearness, dexterity, nor even correctness, of that wonderful contrapuntist: there is not only confusion in the

the parts and design, in many places, but something very harsh and unpleasing in the harmony, particularly in the closes without a sharp seventh, both in the key-note and in the fifth. The motet is in six parts, soprano, two counter-tenors, tenor, baritone, and base. Some of these sevenths would doubtless have been made sharp in performance by the singers of those times, in obedience to a rule for sharpening ascending sevenths in minor keys, and flattening them in descending.

The list of his works, in Walther's Dictionary, though ample, is far from complete. The motet *Verbum bonum*, just mentioned, was published at Fossombrone in 1519, forty-three years before Zarlino made him an interlocutor in his dialogue (*Ragionamento*), at Venice; and it can hardly be imagined that no others of his compositions appeared till 1542, when, we are told, that his motets for six voices were published. In the *Fior de Motetti*, lib. i. Venice, 1539, there is a *Pater-noster*, in four parts, by Adriano; and in the same year the first book of his motets, for four voices, was republished in the same city by Ant. Gardano, in folio, under the following pompous title: "Famosissimi Adriani Willaert, Chori Divi Marci illustrissimæ Reipublicæ Venetiarum Magistri, Musica Quatuor Vocum (quæ vulgo Motectæ nuncupatur) noviter omni studio, ac diligentia in lucem edita." This edition, which, we find by the title, was not the first, is preserved in the British Museum. Indeed, for near fifty years after his name first appeared, hardly a collection of motets or madrigals was published to which he did not contribute; but the most splendid and curious work of this author, that we have seen, is preserved in the British Museum. It was published at Ferrara, 1558, by his scholar and friend, Francesco Viola, another of the interlocutors in Zarlino's *Ragionamento*, under the title of *Musica Nova*, in three, four, five, six, and seven parts. In the dedication of this work to Alfonso d'Este, duke of Ferrara, the editor, his maestro di capella, calls Adriano (the name by which he is always mentioned by the Italians) his master, and says, that he is strongly attached to him, not only for his wonderful abilities in music, but integrity, learning, and the friendship with which he has long honoured him. Zarlino, in like manner, omits no opportunity of exalting the character of his master. These are honourable testimonies of regard, which seem the more worthy of being recorded, as, either from the worthlessness of the master, or ingratitude of the scholar, they are but seldom bestowed.

In the cantus part there is a wooden cut of the author: "Adrian Willaert Flandrii Effigies." And indeed the compositions are of that kind for which he was most renowned, and such as the editor thought would constitute the most durable monument of his glory. In the tenor part there are many canons of very curious construction; some with two and three clefs, and a different number of flats and sharps for the several parts, which are moving in different keys at the same time; and one particularly curious, in seven parts, "Præter rerum seriem," of which three are in strict canon of the fourth and fifth above the guide; the tenor leading off in G, the sextus following in C, and the septima pars in D, while the rest move in free fugue.

Zarlino (P. iii. p. 268.) assigns to Adriano the invention of pieces for two or more choirs; and Piccitoni (*Guida Armonica*) says, that he was the first who made the bases in compositions of eight parts, move in unisons or octaves; particularly when divided into two choirs, and performed at a distance from each other, as then they had occasion for a powerful guide. The dexterity and resources of this author, in the construction of canons, are truly wonderful, as is, indeed, his total want of melody; for it is scarcely possible to

arrange musical sounds, diatonically, with less air or meaning, in the single parts. But there are many avenues through which a musician may travel to the temple of Fame; and he that pursues the track which the learned have marked out, will perhaps not find it the most circuitous and tedious; at least theorists, who are the most likely to record the adventures of passengers on that road, will be the readiest to give him a cast. A learned and elaborate style conceals the want of genius and invention, more than the free and fanciful productions of the present times.

Adriano lived to a great age, and filled a very high musical station, maestro di capella of St. Mark's church at Venice. His works and scholars were very numerous; and among those to whom he communicated the principles of his art, there were several who afterwards arrived at great eminence; such as Cipriano Rore, Zarlino, and Costanzo Porta. In the title of a book, published at Venice, 1549, there are "Fantasia," or "Ricercari," composed dallo eccellentissimo Adrian Vuigliart, and Cipriano Rore, suo discepolo. P. Martini, in his *Saggio di Contrappunto*, P. ii. p. 266. calls Adrian Willaert the master of Costanzo Porta. Burney.

WILLAFANS, in *Geography*, a town of France, in the department of the Doubs; 3 miles S.E. of Ornans.

WILLAKALA, a town of Sweden, in Finland; 48 miles E. of Biorneborg.

WILLAWAKY, an Indian town on the N.W. coast of lake Michigan. N. lat. 47° 45'. W. long. 87° 10'.

WILLDENOVIA, in *Botany*, received its name from professor Thunberg, in honour of Dr. Charles Lewis Willdenow, late professor of botany at Berlin, well known as the author of many learned botanical writings, but especially by his *Species Plantarum*, of which the immortal work of Linnæus, bearing the same title, is the basis. The addition of essential characters, and of many new species, besides those accumulated in profusion, with great intelligence and discrimination, from authors subsequent to Linnæus, might entitle this to rank as an original work; were not the Linnæan part of it too fervile a transcript, not only of mistakes, of remarks contradicting each other, and of evidently false synonyms; but in general of errors of the press, and wrong citations of plates and pages, which prove that the respective books, though in every body's hands, were not consulted. The learned editor happily lived to complete the first part of the fifth volume, comprising the order of *Filices*, in which he was well verfed. That he left the rest of the *Cryptogamia* unattempted, is perhaps rather fortunate than otherwise. The *Musci*, *Lichenes*, and *Fungi*, each form a study by themselves, and are treated of separately by different authors. They would have added enormously to Willdenow's work, and could, after all, have proved but a compilation. If the science goes on as it has done, an universal botanist will be nearly as impossible a character as an universal naturalist is at present.

Another genus (see *SCHLECHTENDALIA*) was dedicated to Willdenow by Cavanilles, which is retained in Lamarck's *Illustrations*, t. 685, by the name of *Vildenovia*. The change of orthography at the conclusion we readily adopt, instead of the uncouth *Willdenowa*, or *Willdenowia*, and it is now likewise followed by Thunberg himself, in his *Flora Capensis*.—Thunb. in *Stockh. Transf.* for 1790, 28. Prodr. 14. Fl. Capenf. v. 1. 312. Willd. Sp. Pl. v. 4. 717. Poir. in Lamarck Dict. v. 6. 177.—Class and order, *Dioecia Triandria*. (*Triandria Monogynia*; Thunb.)—Nat. Ord. *Tripetaloidæ*, Linn. *Junci*, Juss. *Resiliacæ*, Brown Prodr. v. 1. 243.

Gen. Ch. Male, Cal. Perianth inferior, of numerous, imbricated, membranous, pointed, permanent glumes, longer

than the fruit. *Cor.* Petals six, equal, erect, oval, membranous, permanent. *Stam.* Filaments three, capillary, shorter than the corolla; anthers ovate-oblong.

Female, *Calyx* and *corolla* as in the male. *Pist.* Germen superior, roundish; style very short, two or three-cleft; stigmas two or three, downy. *Peric.* Drupa dry, roundish, smooth. *Seed.* Nut solitary, of one cell.

Eff. Ch. Male, *Calyx* of many imbricated glumes. *Corolla* of six petals, permanent.

Female, *Calyx* and *corolla* as in the male. *Style* one. *Stigmas* two or three. *Drupa* with one seed.

Obs. This genus differs from *RESTIO* (see that article), chiefly in having a single-seeded *drupa* instead of a *capsule*, opening by valves, and containing several seeds. We have here merely altered the phraseology respecting the *calyx*, which in *Restio* is termed, rather improperly, a *catkin*.

1. *W. striata*. Striated Willdenovia. Thunb. in Stockh. Transf. for 1790, 27. t. 2. f. 1. Fl. Cap. v. 1. 312. Willd. n. 1. Poiret n. 3.—Stem leafless, round, striated.—Native of the Cape of Good Hope, as are likewise the two following species. The *stem* is two feet high, or more, erect, rushy, hard and rather shrubby, branched, usually simply forked, rarely three-forked, round, jointed, striated, smooth; the branches also round, striated. *Sheaths* at each joint and subdivision solitary, ovate, close, brown, smooth. *Leaves* none. *Flowers* terminal, solitary, erect, the size of a pea. Scales of the *calyx* about ten, rarely fewer, or more, loosely imbricated, equal, oblong, pointed, brown, smooth, the length of the nail, membranous at the edges. *Corolla* white, much shorter than the *drupa*, and pressed close to its sides. *Style* in two short, broad, yellow divisions. *Stigmas* short, obtuse, brown. *Drupa* ovate, black, dotted; sometimes, according to Thunberg, of two cells, which last circumstance, if real, greatly invalidates the generic character.

2. *W. teres*. Smooth Willdenovia. Thunb. in Stockh. Transf. for 1790, 28. t. 2. f. 2. Fl. Cap. v. 1. 314. Willd. n. 2. Poiret n. 1.—Stem and branches leafless, round, smooth and even. The *stem* of this species is shrubby, much branched, jointed, simply or triply forked, erect, a foot or more in height, not striated; its branches somewhat level-topped. *Sheaths* at each subdivision ovate, brown, smooth, as long as the nail. *Flowers* terminal, solitary, erect. Scales of the *calyx* about six, ovate, awned, grey and smooth. *Petals* very short, emarginate, shining, surrounding the base of the fruit. *Style* undivided, very short. *Stigmas* feathery, tapering, purplish. *Drupa* hard, ovate, black, smooth, of one cell.—This plant differs from the foregoing in having fewer *calyx-scales*, a smooth and more branched *stem*, long tapering *stigmas*, and a smooth, not dotted, fruit. Poiret, who had seen a specimen, attributes to the present species the fleshy cylindrical body, with six notches, surrounding the base of the *corolla* externally, which Willdenow calls a *nectary*, and admits into his generic character. We have seen but few and incomplete specimens of any of the genus, and therefore cannot judge of the part in question, but we presume the term *nectary* must here be misapplied. Thunberg does not mention it in his *Flora*.

3. *W. compressa*. Compressed Willdenovia. Thunb. in Stockh. Transf. for 1790, 28. t. 2. f. 3. Fl. Cap. v. 1. 315. Willd. n. 3. Poiret n. 2.—Stem leafy, smooth and even; branches compressed. *Stem* two feet high, or more, shrubby, erect, smooth in every respect, simply or triply forked; its branches compressed, or semi-cylindrical, wand-like. *Sheaths* of the subdivisions ovate, pointed. *Leaves* on the young branches, and resembling them, thread-shaped, tapering. *Flowers* terminal, solitary, upright, the size of a pea. Scales of the *calyx* ovate, awned, smooth, membranous at

the edges. *Petals* ovate, acute, as long as the fruit. *Style* undivided. *Stigmas* three, feathery. *Drupa* ovate, compressed, obtuse, grey. Thunberg.

WILLEBROD, in *Biography*, the apostle of Friseland, was an Anglo-Saxon, and born in Northumberland about the year 658, and educated in the abbey of Rippon, where he engaged in the religious profession. At the age of 33, he accompanied eleven of his countrymen into Batavia, and employed himself for three or four years in converting the Frisians who were under the French dominion; and having met with great success, he went to Rome, and received from pope Sergius the pallium, ordaining him archbishop of Friseland. Pepin gave him a residence at Wilteburg, now Utrecht, of which he was the first prelate. Embarking from Friseland for the north, he penetrated into Denmark, and in his return was cast by a storm on an island called Fosteland, supposed to be the same with Heligoland. He afterwards baptized Pepin, son of Charles Martel, and spent the rest of his life in propagating Christianity among the Batavians. His colleague and assistant was Winfrid, his countryman, surnamed Boniface, the apostle of Germany. He died in 740, at the age of 82; was buried at his abbey of Eternac, in the diocese of Treves, and honoured with canonization. His life was written by the celebrated Alcuin. Mosheim. Moreri.

WILLEMSTADT, or WILLIAMSTADT, in *Geography*, a strong town of Holland, situated upon that part of the Meuse called Buttermiet, built in 1584, by William I., prince of Orange, from whom it receives its name. This fortress is one of the keys of Holland, and defended with seven bastions and double fosse; it has also a good harbour, but which it is sometimes dangerous for vessels to enter at certain times of the year. It was besieged by the French in the year 1793, but by the brave resistance of the governor and garrison, assisted by the English, with gun-boats, &c. the besiegers were compelled to retire with great loss; 12 miles S.W. of Dort. N. lat. 51° 41'. E. long. 4° 18'.

WILLENBERG, or WILDENBERG, a town of Prussia, in the province of Oberland; 93 miles S. of Königsberg. N. lat. 53° 11'. E. long. 20° 53'.

WILLERING, a town of Austria, on the Danube; 4 miles W. of Lintz.

WILLERSDORF, a town of Bavaria, in the bishopric of Bamberg; 5 miles S.W. of Forcheim.

WILLET'S BAY, a bay on the north-west coast of the island of St. Christopher, about a mile to the south-west of Dieppe Bay.

WILLIAM I., called "the Conqueror," king of England, and duke of Normandy, in *Biography*, was the natural son of Robert, duke of Normandy, by Arlotta, the daughter of a tanner, and born in 1024. When his father went on a pilgrimage to Jerusalem, and his son was only nine years of age, he caused the states of the duchy to swear allegiance to William, as his heir. On his return in 1033, Robert died; and the consequence was a variety of dissensions among the barons of the duchy, in which Henry I. of France took a part; so that when William arrived at majority, he found his dominions in a low and distracted state. But his vigour and exertions soon restored order and submission, and general tranquillity through his duchy. Edward the Confessor, at this time king of England, had no children; and the archbishop of Canterbury, who was a Norman, recommended his adopting William as his successor, and he was commissioned by the king to inform the duke of his intention. However, as he had not publicly divulged his purpose, Harold, the son of earl Godwin, ascended the throne without opposition, on his decease

in 1066. Harold, however, had previously taken a solemn oath to assist William in accomplishing the purpose of Edward respecting the succession; and his perfidy excited the indignation of William, and induced him to prepare for dispossessing Harold of the English throne by force of arms. His intentions were no sooner announced than he was joined by a great number of military adventurers; and upon an appeal to Rome, the pope sanctioned the contest, and sent him a consecrated banner. Thus encouraged, he assembled a fleet of 3000 vessels, and an army of 60,000 men; and determining on invading England, landed on September 28, 1066, at Pevensey, in Suffex. Harold, as soon as he received this intelligence, marched from York, and having recruited his forces at London, hastened to encounter the Normans, who were encamped near Hastings. On the 14th of October the two armies engaged, and after a severe battle, which lasted during a whole day, the English were defeated, with the loss of Harold and his two brothers. William lost no time in availing himself of this victory; but having reduced the town and castle of Dover, and received the submission of the Kentish men, proceeded towards London. In his way he was met by Edgar Atheling, who had been proclaimed legal heir to the monarchy, Stigand, archbishop of Canterbury, and some of the principal nobility, who made an offer to him of the crown; and on Christmas-day, 1066, after a kind of tumultuous election, he was crowned at Westminster-abbey by the archbishop of York, and took the coronation-oath. Having adopted measures for conciliating his subjects, and overawing those who were adverse to him, he re-crossed the sea to Normandy, taking with him as hostages Edgar, the primate, and several of the principal nobility. Soon after his departure, the English were treated contumeliously and oppressively by the Normans, whose conduct excited insurrections, and led to a conspiracy for the massacre of all who remained in the country. This intelligence occasioned William's return in December 1067; and among other measures of a more conciliatory nature, he imprudently renewed the tax called "danegelt," which excited insurrections through various parts of the kingdom. As soon as these insurrections were suppressed, his queen, Matilda, was crowned at Westminster: but new troubles arose from the union of the two principal nobles, Edwin and Morcar, with the kings of Scotland and Denmark, and the prince of North Wales, which threatened an extensive revolt. The conspiracy for this purpose was discovered and crushed, and measures were taken for preventing the evils that were likely to result from it. From this time William's government became daily more and more despotic; and the nobility of the country, perceiving that their ruin was the object of his contemplation, prepared to leave the kingdom. Insurrections broke out in various parts of the country, and the means which he adopted for suppressing them were in the highest degree rigorous and destructive. As a measure of future prevention, he brought from Normandy the feudal constitution into England, and divided most of the lands into baronies, which he granted to the most considerable of his followers, under the condition of certain services and payments; and these subdivided their shares on similar tenures, among others, chiefly foreigners, of inferior rank. The ecclesiastical property of the kingdom was regulated upon a similar system; and under various pretences, the Normans superadded the English in the possession of all church dignities. In order to favour this expulsion of the English dignitaries, a legate from the pope was, for the first time, admitted into this country, and a reverence for the see of Rome, similar to that which subsisted on the continent, was inculcated on all British sub-

jects; whilst the king took care, by reserving certain powers to himself, to guard the civil sovereignty against papal usurpations. In order further to subjugate the minds of the English, and reduce them to the state of a conquered people, the king projected the abolition of their language; and by admitting at court no other language besides the French, he caused all the youth in the schools of the kingdom to be instructed in it, and the laws to be drawn up in that language, which was also used in all judicial pleadings and writings.

Having suppressed an insurrection which broke out in 1071 by the instigation of the earls Edwin and Morcar, and in the following year negotiated a peace with Malcolm, king of Scotland, he was called to Normandy in 1073, on occasion of a revolt in that country. In 1075 his presence was necessary in England to check a conspiracy among the Norman barons, whom he had distinguished by his favour, and who were joined by Waltheof, an English nobleman, on whom he had bestowed his niece Judith. Waltheof, in this conspiracy, fell a sacrifice to the treachery of his wife. In the following year, *viz.* 1076, the haughty and ambitious Hildebrand, who was now pope Gregory VII., required William to do homage for his kingdom to the holy see, alleging a promise to this purpose, and also to pay the accustomed English tribute. William denied his promise of homage, which he refused to render, but remitted to Rome the Peter-pence; and whilst he would not allow the English prelates to attend a general council summoned by Gregory, he permitted the pope's legate to convene a synod at Winchester for establishing the celibacy of the clergy. On his return to Normandy in this year, he found the country engaged in a civil war, in consequence of a rebellion excited by his son Robert. On this occasion the father and son had a personal encounter; but when the son discovered that he was thus engaged, he was struck with horror, fell at his father's feet, and implored forgiveness. The father was at first unrelenting; but they were afterwards reconciled. About the year 1081, William ordered that survey of the landed property of the kingdom to be made which is recorded in Domesday-book. (See DOMESDAY. For an account of the impolitic as well as cruel manner in which he indulged his passion for the chase, we refer to the article FOREST.) The latter years of his life furnished various occasions of affliction and disquietude. The death of his queen Matilda, to whom he was affectionately attached, was an event that took place in 1083, and was the cause of undisssembled sorrow and lamentation. The preparations made by the king of Denmark and the earl of Flanders for an invasion of England occasioned to him no small degree of anxiety: and when he was rescued from this danger by the death of the Danish king, he was called into Normandy in 1086, to repel the incursions of some French barons; and suspecting that the king of France had instigated them to these acts of hostility, he commenced a war against him in 1087, in the prosecution of which he even laid waste the country at the approach of harvest by the most cruel devastation. But an accidental injury which he received in mounting his horse stopped his career, and terminated in his death. Alarmed by the near prospect of dissolution, his mind was harassed with remorse in the review of the atrocious conduct with which he was chargeable, and he sought relief by donations to the church, to which persons of his character have commonly resorted, and by the pardon and release of some of his enemies. By his last testament he bequeathed to his eldest son Robert the counties of Normandy and Maine, and to his second son William, the crown of England, and to his third son, Henry, the property of his mother. He expired at the abbey of St. Gervais, near Rouen,

Rouen, on September 9, 1087, in the 63d year of his age, and the 21st of his reign over England, leaving five daughters, as well as sons. "William the Conqueror at his death," says one of his biographers, "was the most powerful and greatest sovereign of his time. He possessed superior talents, political and martial, and employed them with singular vigour and industry. But his passions were strong, his disposition was severe and merciless, and his ambition and love of rule caused him to disregard all restraints of justice and humanity. There never was a more fortunate usurper of a throne, which he transmitted to a long and still subsisting line of descendants; and the establishment of his dynasty is the most conspicuous era of English history." Rapin. Hume. Henry. Lyttleton. Gen. Biog.

WILLIAM II., surnamed *Rufus*, second son of the Conqueror, and king of England by his father's nomination, was crowned at Westminster in September 1087, and recognized as king when he was about 27 years of age. His brother Robert succeeded to the dukedom of Normandy by the disposition of his father, which proved the occasion of much discontent and contest; partly because the great barons possessed estates both in England and Normandy, and under separate governments; and partly because Robert was the eldest son, and the most popular. A conspiracy was soon formed by the maternal brothers of the late king, in which many nobles concurred for deposing William. But William, possessing a certain portion of his father's vigour, took measures for defeating them. With this view he conciliated the native English, took possession of the castles and persons of the unfortunate barons, banished them to Normandy, and bestowed their estates on his faithful adherents. When he was firmly seated on the throne, he forgot his promises of relieving the English from oppression, and even enhanced the severity of the forest laws. The death of Lanfranc, whom he respected, left him at liberty to seize vacant bishoprics and abbeys, and to bestow church lands on his captains and favourites. In 1090 he visited Normandy with hostile intentions respecting his brother; but a negotiation took place, and they were reconciled. Robert accompanied William to England, and commanded an army which was sent against Malcolm, king of Scotland. But a variance soon took place between the brothers, occasioned by the encroaching and treacherous disposition of William, which led him to excite the Norman barons to rebel against Robert. Whilst William was prosecuting hostile measures against his brother, he was recalled to England in 1095, to suppress a conspiracy among the barons in the north, whom he speedily defeated and severely punished. The spirit of crusading having at this time pervaded Europe, Robert was seized with the mania, and mortgaged his dukedom to William for 10,000 marks, in order to enable him to unite with the crusaders in 1096. William, having gone over to the continent to take possession of Normandy and Maine, was taken extremely ill, and apprehending danger, resolved to repair the injury which he had done to the church, and to supply the vacancy of the archbishopric of Canterbury, which had continued from the death of Lanfranc. The ecclesiastic nominated on this occasion was Anselm, who, notwithstanding the disinclination he had manifested against accepting the appointment, was afterwards a zealous defender of the rights of the church, and of ecclesiastical authority in general. The king and the primate soon disagreed; and though a synod was assembled for the deposition of the archbishop, the king failed in the attempt. But when Anselm desired permission to leave the kingdom, he obtained leave; but his temporalities were seized, and the pope received him as a confessor in the cause of religion.

William's French acquisitions were the occasion of trouble to him; for whilst he was hunting in the New Forest, he received information that the citadel of Maine was besieged, and he therefore hastened to Dartmouth, and determined to embark without delay. As the weather was tempestuous, the mariners expressed some apprehension of danger; the king, however, was resolute and persevering, and asked them if they had ever heard of a king who was drowned. Having accomplished his object, he was applied to by the duke of Guienne, who was under the influence of the passion for crusading, for the loan of a sum of money, as a mortgage on his rich provinces of Guienne and Poitou. William accepted the proposal; but whilst he was preparing to carry over the money, and to take possession of the provinces, he was accidentally killed in the New Forest. Having alighted from his horse after a chase, a stag sprung up near him; and a French gentleman, Walter Tyrrel, perceiving the animal, shot off an arrow, which glancing from a tree, entered the king's breast, and penetrated to the heart. Tyrrel immediately fled, and embarking for France, joined the crusaders. The king's body was found by the country people, and interred without ceremony at Winchester. This happened on August 2, 1100, when the king was in the 40th year of his age, and the 13th of his reign. The character of William Rufus has been unfavourably represented, both on account of the depredations which he committed in the church, and of his indifference to religion. "The incidents of his reign," says a biographer, "prove him to have possessed vigour and decision, courage and policy; but to have been violent, perfidious, and rapacious, and void of all sense of justice and honour. One of his best public acts was the sending Edgar Atheling into Scotland, to restore prince Edgar, son of Malcolm, to the throne of that kingdom, of which he was the lawful heir. He deserves to be regarded as a promoter of the useful arts by his still-remaining erections of the Tower, London-bridge, and Westminster-hall." Gen. Biog.

WILLIAM III., king of England, prince of Orange, and stadtholder of Holland, was the posthumous son of William II., prince of Orange, and of Mary, daughter of Charles I., king of England, and born on November 14, 1650, at a very interesting period. His guardianship was divided between the princess-royal his mother, the princess-dowager his grandmother, and the elector of Brandenburg. During the negotiations that succeeded the naval war between the English and Dutch republics, Cromwell, the protector, stipulated, that the prince of Orange, who was a branch of the house of Stuart, should be for ever excluded from the stadtholderate; but on the event of the Restoration, the princess-royal petitioned, in 1662, that her son might be invested with the offices and dignities which belonged to his ancestors; and soon after the act of exclusion against him was annulled. Although the states of Holland would not admit, as a condition of peace in the succeeding war between England and the United States, the preliminary proposed by Charles II. of elevating the prince to the stadtholderate, they formally adopted him as "a child of the state," and placed him under the care of persons who should inspire him with principles suited to his situation under a free government. After some subsequent debates concerning the rank which should be assigned him, he was raised in 1670 to the dignity of first noble of Zealand, and then admitted into the council of state. On occasion of the war, which was declared by Lewis, and his pensioner Charles, against the United States in 1672, the public voice obliged the magistracy of Holland to revoke the perpetual edict procured by De Witt for abolishing the stadtholderate,

WILLIAM.

ate, and to confer that dignity with all its prerogatives upon William. Thus authorized by the States to change the regency in all the most considerable towns of Holland and Zealand, party opposition was extinguished, and every proposal for the defence of the country was unanimously adopted. The prince, at this early age, fully justified the confidence that was reposed in him by the firmness and elevation of his mind. At an extraordinary assembly of the states, he pointed out, in an elaborate speech, the pernicious consequences that must result from the "peace proposed by the French king, who was in possession of three of the provinces; he shewed the possibility of raising supplies for a war in defence of their religion and liberty; and by the cool intrepidity of his manner and force of his arguments, he produced such an effect upon his before-desponding audience, that they concurred in the resolution of making every sacrifice, rather than desert the cause of their country. Vigorous measures were entered upon; foreign alliances were formed; fortunate circumstances prevented the further advance of the French, who evacuated the province of Utrecht; Charles II. was obliged by his parliament to make peace, in 1674, with the Dutch, who in the same year signed separate treaties with the bishop of Munster and the elector of Cologne; and at length the three conquered provinces were re-united to the States General; and the conduct of the prince of Orange so much ingratiated him with the states of Holland, that the offices of stadtholder and captain-general were declared hereditary in his male line." In all his military actions, he displayed both courage and wisdom; so that the prince of Condé testified in his favour, that at the battle of Seneff, "he had in every point acted like an old captain, except in venturing his life too like a young soldier." The humiliation of the French king seems to have been his favourite object; and with this view he wished to fix the English court in the same interest. This was one motive which induced him to connect himself more closely with the royal family, by a marriage with Mary, eldest daughter of the duke of York. Accordingly he came into England in 1678, and then the nuptials took place which were so satisfactory to the nation, and which were afterwards followed by the most important consequences. Without enlarging on the measures pursued by the prince on the continent, we shall direct our attention to those in which our own country was more immediately interested. The succession of the prince's father-in-law to the crown of England in 1685, instead of strengthening the bonds of affinity by which they were attached to one another, served only to separate them more widely. The king was a bigotted papist, and the prince was regarded as a great supporter of the Protestant cause on the continent, and therefore they could not cordially concur in their views and operations. King James, whose object was to render the Catholic religion predominant, began with endeavouring to procure for it a free toleration in Great Britain, by a repeal of the penal laws and the test-act; and in order the more effectually to accomplish his purpose, he strongly solicited the prince of Orange to express his concurrence and that of the princess; but as they knew how unpopular the design was in England, they refused to grant it. About this time Lewis XIV., under the impulse of his own bigotry, and that of those with whom he acted, repealed the edict of Nantes, which had secured the privileges of his Protestant subjects; and by his harsh treatment of them, drove numbers of them out of his dominions, and thus excited a dread and hatred of popery through all Protestant countries of Europe. The effect of this measure with regard to the prince of Orange was, that it sus-

pending all party opposition to him in Holland, and gave him additional importance in Europe, as the determined foe of French ambition. The arbitrary proceedings of king James alarmed all the friends of civil liberty, and of the established religion in England; and apprehensive of danger, they directed their views to the prince of Orange as their deliverer. Accordingly conferences were held with a confidential envoy whom he sent over to ascertain the public opinion; applications were made to the prince by several persons of rank; and at length, when the birth of a prince of Wales disappointed all hopes of a Protestant succession, the leading men of different parties concurred in actually inviting him to come over, and to undertake the protection of the church and constitution from threatening ruin. The prince consented, and with consummate prudence and secrecy prepared for the interesting expedition; and as existing circumstances afforded a prospect of a breach between the United States and their allies, and the king of France, he was thus enabled to augment the Dutch forces by sea and land without suspicion. Having previously dispersed through the kingdom a declaration, stating the grievances of the reign, and announcing his intention of bringing over an armed force to defend the nation from tyranny, and to procure the assembling of a free parliament, he put to sea in October 1688, with a fleet of about 500 vessels, and an army of 14,000 men. He was once driven back by a storm, but a second attempt succeeded, so that he gained the English coast without opposition, (the king's fleet being wind-bound,) and on the 5th of November disembarked his troops at Torbay. Of the causes, progress, and termination of the Revolution, we have given an account under the articles JAMES II. of England, and REVOLUTION. King William seated on the throne became sovereign of a powerful kingdom; but his tranquil possession of the crown depended on a variety of circumstances which he could neither direct nor controul. The conflict of different parties was not easily restrained; nor were his disposition and manners, which were cold and reserved, notwithstanding all his excellent qualities, adapted to unite and conciliate the partisans of the old and new government. Amongst those who had taken an active part in the late measures, or who had acquiesced during their progress, some were dissatisfied with the total exclusion of James and his infant son; and others could not approve the transfer of the crown by the will of the people. In Scotland, the appointment of William was the act merely of the whigs; and in Ireland, where the population was chiefly Catholic, the interest of James was predominant. The church zealots in England were not pleased with the tolerant principles manifested by king William, and with the wishes he expressed for the comprehension of the dissenters. Thus circumstanced, the commencement of his reign was embroiled by the open opposition and secret intrigues of his enemies, and in the progress of it the collision of parties was the occasion of much personal disquietude both to him and to the queen. His attention was for a considerable time distracted by the state of his native country, when war with France was renewed in 1689, by James's invasion of Ireland in the spring of that year, when his interest with the Catholics was powerful, and in which he was aided by the French king, and also by an insurrection of the Jacobite party in Scotland. Ireland seemed at this time to demand his principal exertions; for though marshal Schomberg had been sent over in 1689 to oppose the progress of the late king, little had been done to any important purpose. Accordingly in the summer of 1690, he embarked with a reinforcement for this country, and by the battle of the Boyne, in which Schomberg was killed,

he routed the Irish army, and totally dispersed it. James abandoned the contest, and fled precipitately to France, leaving the reduction of the island to William, which was completely effected in the following year. Whilst he was thus engaged in military operations, a party spirit agitated his domestic government. The convention parliament, consisting of whigs, who were his decided friends, dreaded monarchical power, and refused to settle upon him the crown revenue for life. Hence he was led to dissolve the parliament in disgust; but he soon found that the new parliament, in which the influence of the tories preponderated, though it readily indulged his desires with regard to the revenue, and voted liberal supplies for the Irish war, was composed of persons that were not real friends to the principles which placed him upon the throne. We shall leave to the details of history the events that occurred on the continent in the prosecution of the war against France; and proceed to observe, that in the year 1695 he suffered a severe loss by the death of queen Mary, who had proved herself an affectionate wife, and both faithful and zealous in promoting his interest; nor was his attachment to her less ardent and sincere. The decease of Mary revived the hopes of the Jacobites, and they were busy and active in forming conspiracies, not scrupling to concert the atrocious plan of assassinating the king. In 1697 peace with France was concluded at Ryfwick, and Lewis was reduced to the necessity of acknowledging William as the lawful sovereign of Great Britain, and to make no future attempts for dispossessing him of his throne. The next contest that engaged political parties at home related to the reduction of the military establishment. King William, attached to a military life, and not very confident with respect to his own security on the throne, wished to retain a greater force than parliament was disposed to allow; which was no more than 7000 men, who were to be all natives; so that he was under a necessity, though with great reluctance, of parting with his favourite Dutch guards. The next political object that engaged the king's attention was connected with the balance of power in Europe, and that was the succession to the crown of Spain, upon the death of Charles II., who was in a declining state of health, and who had no issue. In 1701 the king of Spain died, and left a testament in favour of the grandson of Lewis XIV., which will was accepted by the French king; and of course preparations were made by William and the Dutch for renewing the war with France. This measure was further rendered necessary by the death of James II. in the same year, and Lewis's acknowledgment of his son as king of Great Britain. On the meeting of the parliament at the end of this year, William made a speech on the state of affairs, on his own proposed conduct, and on the necessity of mutual confidence between the crown and people. This speech was much applauded, and was answered by a very loyal address. Thus was his reign, which had been distinguished by its vicissitudes and trials, and by the extensive and permanent benefits that resulted from it, drawing to its termination. A fall from his horse gave a shock to his enfeebled constitution, and brought on a fever, the issue of which he tranquilly expected; and he expired on the 8th of March, O.S. 1702, in the 52d year of his age, and 13th of his reign.

The character of king William has been variously delineated by political writers of different sentiments and dispositions. All allow that he possessed considerable political talents, and though in his military operations he was often unsuccessful, few persons exceeded him in his ability for repairing losses, and making a good close of a campaign. Although, as we have before said, his manners were cold

and reserved, he was not destitute of sensibility. The partisans of James, and those who disapproved of the Revolution, have censured his conduct in deposing his father-in-law; but public liberty and the welfare of a nation must be ever regarded as paramount to private duties. He never sought power otherwise than for accomplishing the important and beneficial ends to which his views were directed; and therefore he cannot be justly charged with a culpable degree of ambition. Whatever may be the opinion of erroneous and interested individuals of the Jacobites and tories of more ancient or modern times, "he will ever be gratefully remembered," as one of his biographers says, "by the United Netherlands; as the great founder of their freedom and independence; and will be honoured as the deliverer of the British islands from tyranny, civil and religious, as long as a due sense of the benefits of that deliverance subsists among their inhabitants."

Though the Jacobites in England would not allow that this prince had any music in his soul, Bonnet Bourdelot, in his "*Hist. de la Mus. et de les Effets*," says, "that he had been informed by a friend, one of the attendants of the prince of Orange, afterwards king of England, that in the year 1688, the prince being then at the Hague, and, as may be supposed, deeply engaged in reflexions on the critical situation of his affairs at that time, had three choice musicians to play to him whenever he found himself too much agitated and thoughtful."

WILLIAM of Nassau, prince of Orange, and founder of the Dutch republic, was born in Germany in 1533, and descended from Lutheran parents, though, being introduced into the service of Mary queen of Hungary, and afterwards of Charles V., he conformed to the Catholic religion. He was trained to military and civil employments of high rank; and as he had ample possessions in the Low Countries, he attained to the dignity of governor of the provinces of Holland, Zealand, and Utrecht, under the Spanish government. His character is very highly drawn, and is said to have combined magnanimity, prudence, bravery, equanimity in all fortunes, singular penetration and sagacity, retentive memory, popular eloquence, and the art of conciliating men's affections. Upon the introduction of the inquisition by the bigotry of Philip II., a flame broke out in the Netherlands; and the prince of Orange, with the counts Egmont and Hoorn, did every thing in their power to restrain the severities exercised on a religious account, and to induce the Spanish court to recal cardinal Granvelle, to whose influence solely they were owing; and in this effort they succeeded in 1564. On occasion of the sanguinary measures proposed in the councils of Philip, and carried into execution by the duke of Alva, the prince of Orange, the moderation of whose temper caused him to be suspected, surrendered his employments, and retired with his family, in 1567, to his brother at Nassau. Alva, having arrested counts Egmont and Hoorn, and occasioned them to be condemned and executed, cited the prince of Orange to answer charges of sedition and treason that were preferred against him; and on his non-appearance, his estates were confiscated, and his eldest son, a student at Louvain, was carried off into Spain. William, who about this time seems to have declared himself a Protestant, levied an army with a view of penetrating into Brabant; but Alva's military skill defeated his purpose, and he was under a necessity of disbanding his troops. Still determined on relieving his country, he made another application in 1571 to several Protestant powers for succour, but they were all averse from encountering the power of Spain. At length he obtained from the court of France some supplies of money, and was then enabled to fit out a small squadron, which, in

WILLIAM.

in 1572, took possession of the port of Brill. This trivial success roused the spirits of the Netherlanders, and several places in Zealand and Holland declared for the Orange party. At length a convocation of nobles and deputies from the principal towns in Holland took place at Dordrecht, and forming themselves into an independent state, chose William for their chief. Convinced by the massacre of the Protestants in France, that it was in vain to expect assistance from that quarter, he dismissed his troops, and retired to Holland; and whilst Alva was exercising his usual severities, the people of Holland and Zealand alone remained in arms against the Spanish government; and the presence of William gave order and stability to the new republic. Although the duke of Alva was recalled from his government in 1573, the cause of independence was in a very precarious state. However, in 1574, the states of Holland and Zealand conferred on William the sovereign authority during the war, and formed a treaty of union and alliance with each other. Peace with the court of Spain could not be obtained otherwise than on terms which could not be accepted; and the aspect of affairs in 1576 was very discouraging. At length, however, the death of Requesens, who had succeeded Alva as governor, and the depredations to which the towns of Brabant and Flanders were exposed, favoured William in his efforts to accomplish a general union of the provinces of the Low Countries for mutual defence; and this was effected by the treaty, called the pacification of Ghent. William was now justly regarded as the true patron of public liberty. At the beginning of the year 1579, the duke of Parma being the Spanish governor, the union of Utrecht was signed, which was the basis of the confederation of the Seven United Provinces, all of which, by their deputies, concurred in forming it. When the separation of the Catholic and Protestant Netherlands took place, the latter, being distressed, sought the assistance of France, by nominating, in 1580, the duke of Anjou, brother to Charles IX. king of France, for their sovereign, and renouncing their allegiance to Philip; but the administration of Holland and Zealand was still entrusted with the prince of Orange. Philip, ascribing this measure to William, issued an edict of proscription against him; in consequence of which his life was in danger, and an attempt was made to assassinate him. At length he fell a victim to the fanaticism of a native of Franche-Compte, who was urged forward by a Cordelier and a Jesuit, who, under pretence of business, obtained access to him, and shot him through the body. He fell, and ejaculating "My God! have mercy upon me and thy poor people," instantly expired, on July 10, 1584, having nearly completed his 52d year. He was interred with great honour and testimonies of respect, at Delft. He was four times married, and had issue by each wife. His second son, Maurice, succeeded to his authority in the United Provinces. (See MAURICE.) William, having been educated in a court, acquired the manners and habits of a statesman, and was charged with dissimulation and proud ambition. But his objects were always pure and patriotic, and he zealously preserved the liberties of his country; and, though he has been traduced by the advocates of despotism, he has received the highest tokens of respect from a people who gratefully acknowledge him as the principal author of their freedom and independence. Univ. Hist. Gen. Biog.

WILLIAM of Wykeham, an English prelate, was born in 1324, at Wykeham in Hampshire, and by the liberality of a patron, educated at Winchester school, and afterwards recommended to Edyngdon, bishop of Winchester, who introduced him into the service of king Edward III. about his

23d year. Acquiring extraordinary skill in architecture, he was appointed in 1356 clerk of the king's works in two manors, and surveyor of the royal works at the castle and in the park of Windsor. The king was so highly satisfied with his conduct in these similar departments, that he recommended him by several preferments, civil and ecclesiastical. In 1359 he was nominated chief warden and surveyor of the royal castles of Windsor, Leeds, Dover, and Hadlam, and of several other castles, manors, and parks. Whilst he had only the clerical tonsure, he enjoyed many ecclesiastical dignities; and, in order to his further advancement in the church, he was ordained priest in 1362. In the following year he was made warden and justiciary of the royal forests south of Trent, and in 1364 keeper of the privy-seal. He was also chief of the privy-council, and governor of the great council; and besides other civil preferments which he enjoyed, he succeeded Edyngdon, in 1366, as bishop of Winchester, which paved the way for his elevation to the post of high-chancellor in 1367, of which latter dignity, however, he was divested in 1370. Thus possessing ample means of munificence in a state of celibacy, and a liberal spirit, his profession as an architect led him to repair and erect numerous buildings in his fee at an expence of no less than 20,000 marks. He also directed his attention to the improvement and proper discipline of the religious houses comprehended within his diocese. For the better education of his clergy, he laid the foundation of a college in Oxford, which was to be supplied with students from a seminary at Winchester. He was interrupted, however, in his liberal designs of general utility by an impeachment for misconduct in the administration of public affairs, occasioned by the influence of the duke of Lancaster, who had conceived a prejudice against him; and, in consequence of this impeachment, his temporalities were seized to the king's use, and he was banished from court. The clergy, however, interfered, and the people regarded him as a sufferer from the duke's exorbitant power; so that a tumult ensued, that procured the restoration of his temporalities, and his recovery of the royal favour, a little while before the king's death. During the turbulent reign of Richard II. Wykeham conducted himself with caution, and succeeded in the establishment of his two colleges. For that at Oxford he obtained a patent in 1379, and it was completed in 1386. It is now known by the name of the New college. His college or school at Winchester was finished in 1393. He also undertook the repair of the cathedral, which was a Saxon edifice of the eleventh century, and in the course of ten years rebuilt it in the Gothic style. (See WINCHESTER.) In 1384 he was induced, against his inclination, to accept the office of high-chancellor, which he resigned again in 1391, after having restored the public tranquillity. When the king recovered his authority, he procured a parliament in 1397, which impeached several of the commissioners, who had almost divested him of his authority, of high treason; but Wykeham, who was one of them, escaped with a forced loan of 1000*l.* He attended the first parliament of Henry IV. in 1399, which deposed Richard, but was not present at the council, which adjudged him to perpetual imprisonment. As his health declined, he was disabled from performing the duties of his office; and therefore nominated coadjutors in his bishopric, settled all his temporal and spiritual concerns, and with tranquillity waited his dismissal from the world. This happened in September 1404, when he had finished his 80th year. His remains were interred in his own chapel or oratory in Winchester cathedral, where a tomb of white marble was erected to his memory. Lowth's Life of William of Wykeham. Biog. Brit.

WILLIAM, *Sweet*, in *Botany*. See DIANTHUS, and PINK.

WILLIAMS, DANIEL, D.D. in *Biography*, an eminent non-conformist divine, was born at Wrexham, in Denbighshire, about the year 1643 or 1644. The disadvantages of his early education were counterbalanced by the natural vigour of his mind, and by future application. Devoting himself to the ministry among Protestant dissenters, he was one of the first who had resolution to engage in it, after the privations and sufferings which followed the Act of Uniformity in 1662. At the age of 19 years he was admitted a preacher among the Presbyterians, and for several years officiated occasionally in several parts of England. Being here in danger of persecution, he accepted an invitation to become chaplain to the countess of Meath in Ireland, where dissenters enjoyed a greater degree of liberty; and some time afterwards he became pastor to a respectable congregation in Wood-street, Dublin. Here he continued for nearly twenty years, exercising his ministry with acceptance and usefulness, and conducting himself so as to maintain harmony with his brethren in the ministry, and to secure respect and esteem from the Irish Protestants in general. During his residence in Dublin, he married a lady of an honourable family, with a considerable estate. Towards the close of the reign of James II., his opposition to popery rendered his situation in Ireland unpleasant to him, and he therefore came over to England in 1687, and settled in London. Here he joined those ministers who opposed an address to the king on occasion of his dispensing with the penal laws; and by his firmness and intrepidity contributed in no small degree to their unanimous rejection of it. Out of his own funds, and by his wealthy connections, he procured relief for those Irish Protestants who sought refuge in London from the tyranny and persecution of Tyrconnel. After the Revolution in 1688, which was an event that gave him and his brethren inexpressible satisfaction, he was often consulted by king William on Irish affairs; and his reports concerning the abilities and character of Irish refugees, who were capable of serving the government, were duly regarded. On occasion of his visit to Ireland, in the year 1700, for settling his own affairs, his conduct in the instances now specified was gratefully acknowledged. Towards the latter end of the year 1688, he was unanimously chosen pastor to a numerous congregation of Presbyterians in Hand-alley, Bishopsgate-street; and in this connection he spent the remainder of his days, devoting to charitable purposes the salary which he received from his congregation. With the famous Richard Baxter he cultivated an intimate acquaintance; and at his death, in 1691, he was chosen to succeed him at the Merchants' Tuesday lecture in Pinners'-hall. Some of his fellow-lecturers advanced what he conceived to be Antinomian tenets; and these dangerous notions he thought it to be his duty to oppose. Hence arose a suspicion of his orthodoxy, and an attempt to exclude him from the lecture. Their design was frustrated by a majority of the subscribers; but as their opposition was inveterate, it was thought most advisable to separate and to establish another Tuesday lecture at Salters'-hall. Three of the most respectable of the old lecturers, *viz.* Dr. Bates, Mr. Howe, and Mr. Alfop, seceded with Mr. Williams.

Upon the publication of the works of Mr. Crisp, who avowed himself the champion of Antinomianism, Mr. Williams undertook to refute them; and in 1692 published his "Gospel Truth stated and vindicated, &c." 8vo.; a work which, though now almost forgotten, was deservedly approved by the principal London ministers of that period; and as it is distinguished by great clearness and strength of

argument, as well as a truly Christian temper, it served to check the pernicious errors which were then industriously circulated. It was defended by the author in his "Defence of Gospel Truth, &c." 8vo., and in a "Postscript" to a new edition of his work, and also in other pieces. Against the charge of Socinianism, an appeal was made to Dr. Stillingfleet, then bishop of Worcester, and Dr. Jonathan Edwards of Oxford, who were deemed masters and judges in this controversy; and they honourably acquitted the author, with many expressions of respect for him. Disappointed in their efforts to induce suspicion of his orthodoxy, his enemies indulged their malignity further by arraigning the purity of his morals. Indignant as he well might be at this attack, he submitted his conduct to the investigation of the United London Ministers, who concurred in the report of their committee, "that he was entirely clear and innocent of all that was laid to his charge." The attachment of his congregation, it should be observed, was not in the least degree diminished by the malignant misrepresentations of his enemies.

In the year 1701, Mr. Williams, after having been for some time a widower, married a second wife of considerable fortune and distinguished worth, who survived him.

During the reign of queen Anne he exerted himself, though ineffectually, in opposing the bills against occasional conformity, and for imposing the sacramental test upon the dissenters in Ireland. In 1707 he used all his influence with his friends in Scotland in promoting the union between the two kingdoms; and in the year 1709 he was honoured with the degree of D.D. by the universities of Edinburgh and Glasgow. Availing himself of his long acquaintance with the earl of Oxford, he took the liberty of remonstrating against the political measures which he was pursuing. The doctor's frankness did not please the statesman; and his resentment against him for declaring unfavourable sentiments of the measures of his administration, and communicating them to his friends in Ireland, was deep and permanent. Upon the accession of king George I., he had the honour of presenting an address of congratulation to his majesty, at the head of the Protestant dissenting ministers of the different denominations residing in London and its vicinity; and it has been ever since the custom for the body of such ministers to present addresses on all public occasions, and they have the honour, as a body, of being received on the throne, and by their committees in the closet, and of receiving a written answer. Soon after the accession of George I., the health of Dr. Williams began to decline; and at length an asthmatic disorder terminated his life on January 26, 1715-16, in the 73d year of his age. In the sequel of this article we shall take advantage of literally transcribing the well-written account given of Dr. Williams by the Rev. Mr. Morgan, the highly respectable and much esteemed librarian of the excellent institution which he has established; under whose inspection and care this library is gradually rising into a reputation, which, by the contributions of its friends in books and money, and by the annual appropriation of a small sum out of the surplus of its founder's bequests, will vie with the principal establishments of a similar nature in the city of London.

"He had been blessed by nature," says our biographer, "with a strong and vigorous constitution, and possessed a sound penetrating judgment, and great strength of memory. The subjects of his pulpit performances were always practical and useful; his sentiments solid, pertinent, and distinguished by an uncommon variety; and his manner of enforcing them powerful and impressive. He was remarkable for his boldness and courage in avowing and defending what

he conceived to be truth of importance, and 'pursued what he thought right with a blunt integrity and unshaken resolution.' At the same time his candour towards those who differed from him, his kind treatment of persons who had endeavoured to injure his own reputation, and his conscientious tender regard for that of others, were prominent features in his character. He was a steady non-conformist upon principle; yet he maintained a charitable disposition towards the established church, and at the Revolution was very desirous of promoting the scheme of a *comprehension*. Though he possessed an ample fortune, he exercised great frugality in his personal expences, for the noble purpose of being more useful to others who stood in need of assistance, and of more effectually serving the great interests of truth and virtue. The same laudable views governed him in the final disposal of his property. By his last will, besides liberal benefactions to numerous benevolent and charitable institutions in London and Dublin, he provided for the support of an itinerant preacher to the native Irish, of two persons to preach to the Indians in North America, and of several charity-schools in England and Wales. He directed that a certain fixed sum, from the income of his estates, should be appropriated to the assistance of poor ministers, the widows of poor ministers, students for the ministry, and to other benevolent purposes. He also left estates to the university of Glasgow, which at present furnish handsome exhibitions to six students for the ministry among Protestant dissenters in South Britain, who are to be nominated by his trustees. The last grand bequest in his will was for the establishment of a library in London, for the benefit of the public. Having formed this design, he purchased Dr. Bates's curious collection of books, which he added to his own, and directed his trustees to provide a proper building for their reception. Such an edifice was erected by them in Red-Cross-street, Cripplegate, where the library was opened in 1729, and admission to it is easily obtained by persons of every description, without any exception, upon application to one of the trustees. Since it was first established, very considerable additions have been made to it by legacies, as well as gifts of money and books; and it now contains upwards of 16,000 volumes, many of which are very valuable and rare, in the various departments of literature and science. The founder's works were collected together, and printed at different periods, in 6 vols. 8vo.; the last consisting of Latin versions of several of his tracts, which he directed to be published in that language for the use of foreigners." Memoir prefixed to his Works.

WILLIAMS, in *Geography*, a township of Pennsylvania, in Northampton county, with 1243 inhabitants; 60 miles N. of Easton.

WILLIAM'S Port, a town of Maryland, on the Potomack; 5 miles S.W. of Hagars Town.

WILLIAM'S River, a river of Vermont, which runs into the Connecticut, N. lat. 43° 10'. W. long. 72° 24'.

WILLIAMSBOROUGH, a post-town of North Carolina, on a creek which falls into the Roanoke; 48 miles N.E. of Hillsborough.

WILLIAMSBURG, a county of the state of South Carolina.—Also, a county of the state of Virginia.—Also, a town of Virginia, situated on an isthmus between York river and James river, a creek from each river coming up within a mile of the town, but not navigable for large vessels. It was at one time the seat of government and residence of the governor, now removed to Richmond. It contains about 200 houses, and 1200 inhabitants. The principal buildings are a college and town-house, an episcopal church, and an hospital for lunatics; 50 miles E.S.E. of Richmond. N. lat. 37° 13'. W. long. 76° 50'.—Also,

a town of Massachusetts, in Hampshire, with 1122 inhabitants; 8 miles N.W. of Northampton.—Also, a town of New York, on the Genesee; 288 miles N.N.W. of Philadelphia.—Also, a town of the state of Ohio, on the Little Miami, in the county of Clermont, with 1251 inhabitants.—Also, a town of Maryland; 4 miles N. of Talbot.

WILLIAMSEURG, or *Jonestown*, a post-town of Pennsylvania; 23 miles E.N.E. of Harrisburg.

WILLIAMSON, a township of Ontario county, in New York, 206 miles from Albany, bounded N. and W. by lake Ontario. In 1810 the whole population consisted of 1139 persons, and it had 55 senatorial electors. A red oxyd of iron is found in this town, which is a good pigment for painting.

WILLIAMSON, a county of West Tennessee, with 13,153 inhabitants, including 3985 slaves.

WILLIAMSPORT, a post-town of Pennsylvania, on the west branch of the Susquehanna, in the county of Lycoming, with 344 inhabitants.

WILLIAMSTOWN, a township of the state of Vermont, in Orange county, with 1353 inhabitants; 60 miles N. of Norwich.—Also, a post-town of North Carolina, on the Roanoke; 55 miles W. of Halifax.—Also, a town of Massachusetts, in the N.W. corner of the state, in the county of Berkshire, with 1843 inhabitants; 132 miles W.N.W. of Boston.—Also, a post-township of Oneida county, in New York, erected in 1805, from a part of Mexico, and consisting of two townships of Scriba's patent, each being six miles square. The population in 1810 consisted of 562 persons, and 82 senatorial electors. The post-office was established in 1812.

WILLICHIA, in *Botany*, was so called by Mutis, after Dr. Christian Lewis Willich, a physician at Clausthal, in Lower Saxony, who published at Gottingen, in 1747, 1762, and 1766, various observations and illustrations of Botany, of more or less importance, chiefly relating to the determination of species and their synonyms, with cursory remarks on variations or irregularities of structure, exceptions to received characters, &c. The author died in 1776.—Linn. Mant. 553. Schreb. Gen. 32. Willd. Sp. Pl. v. 1. 189. Vahl Enum. v. 2. 39. Mart. Mill. Dict. v. 4. Juss. 418. Poir. in Lamarck Dict. v. 8. 798.—Class and order, *Triandria Monogynia*. Nat. Ord. uncertain, Juss. We should presume *Scrophularia*.

Gen. Ch. Cal. Perianth inferior, of one leaf, in four ovate, acute, spreading, permanent segments. Cor. of one petal, wheel-shaped, twice the length of the calyx: tube scarcely any: limb flat, in four roundish, convex segments. Stam. Filaments three, inserted into the clefts of the limb, except the lowermost, and shorter than its segments; anthers erect, roundish, of two cells. Pist. Germen superior, roundish, compressed; style thread-shaped, the length of the stamens, declining towards the lower cleft of the corolla; stigma obtuse. Peric. Capsule roundish, compressed, sharp-edged, of two cells and two valves, with an opposite partition. Seeds several, roundish, minute. Receptacle glo-bular, formed of two hemispheres.

Ess. Ch. Calyx four-cleft. Corolla four-cleft. Stamens in three of its clefts. Capsule superior, of two cells, with many seeds.

1. *W. repens*. Creeping Willichia. Linn. Mant. 558. Willd. n. 1. Vahl n. 1.—Gathered in Mexico, by Mutis, whose description, communicated to Linnæus, is our only source of information concerning this plant. The root is fibrous, annual. Stem herbaceous, creeping, thread-shaped, branched, hairy, about two feet in length. Leaves alternate, stalked, rather distant, orbicular, somewhat peltate,

crenate, hairy, an inch in diameter; reddish underneath. *Footstalks* very long, hairy, thicker than the stem. *Flower-stalks* axillary, in pairs, single-flowered, thread-shaped, hairy, the length of the footstalks. *Flowers* small, rose-coloured, with a hairy calyx.

There is no specimen in the Linnæan herbarium.

WILLIESBURG, in *Geography*, a post-town of Virginia; 2½ miles S.S.W. of Washington.

WILLIMANTIC, a river of Connecticut, which runs into the Shetucket at Windham.

WILLINCK, a large township of New York, at the S. end of Niagara county, erected in 1808; 315 miles W. of Albany. It comprises about eighteen townships of the Holland company lands. The general character of the soil is, that it is good land for farming. In 1810 the population consisted of 2028 persons, and there were 260 senatorial electors.

WILLING'S CREEK, a river of West Florida, which runs into the Mississippi, N. lat. 30° 49'. W. long. 91° 21'.

WILLINGBOROUGH, a town of New Jersey, in Burlington county, with 619 inhabitants; 14 miles N.E. of Philadelphia.

WILLINGTON, a town of Connecticut, in Tolland county, with 1161 inhabitants; 6 miles E. of Tolland.

WILLIS, BROWNE, in *Biography*, an eminent antiquary, the grandson of Dr. Willis, a celebrated physician, was born at Blandford in 1682, and was removed from Westminster-school in the year 1690 to Oxford, where he was admitted a gentleman-commoner of Christ-church; and after leaving the university he prosecuted his studies for three years under Dr. Wotton. When he came into possession of the family estate, he was returned in 1705 as a representative for the town of Buckingham. In 1715 and 1716 he published two parts of a work, intitled "Notitia Parliamentaria; or, a History of the Counties, Cities, and Boroughs in England and Wales, with Lists of all the Knights, Citizens, and Burgeſſes," 8vo., to which in 1750 he added a third part, being an appendage to the journals of the house of commons, then printed. On the revival of the Society of Antiquaries in 1717, he was chosen a member; and he sustained his reputation as an antiquary by various writings, among which are, "Surveys of the Four Welsh Cathedrals;" "History of the United Parliamentary Abbeys and Conventual Cathedral Churches;" "Survey of the Cathedrals of England, with Parochiale Anglicanum," 3 vols. 4to.; "History and Antiquities of Buckingham." In 1723 he received, in consideration of his literary merit, from the university of Oxford, the degree of A.M. by diploma. He manifested his attachment to the church by expending considerable sums in repairing those in the country, and thus injured his own fortune. But frugality in his personal and domestic expences compensated this injury. He possessed a fine cabinet of English coins, which in 1741 he presented to the university of Oxford; the university, in consideration of his family, liberally paying for those of gold by weight, and conferring upon him the degree of LL.D. With many peculiarities in his character, he claimed respect as a man of moral worth from those who knew him. To him belonged the honour of having first placed the English ecclesiastical history and antiquities upon the firm basis of records and registers, which he assiduously searched. He died in 1760, in the 78th year of his age. Biog. Brit.

WILLIS, THOMAS, an eminent physician, was born in 1621-2, at Great Bedwin, in Wiltshire; and in 1636 admitted into Christ-church college, Oxford, where he took the usual degree with a view to the clerical profession. But he changed his purpose, and studied physic, taking his

bachelor's degree in 1646, and commencing medical practice at Oxford. He distinguished himself by his steady attachment to the church of England, and also by his love of science, so that he became one of the first members of that philosophical society at Oxford, which laid the foundation of the Royal Society of London. As a chemist, which was the character under which he was ambitious of excelling, he published in 1659 a work, intitled "Diatribe duæ; prior agit de Fermentatione, altera de Febribus. His accessit Dissertatio epistolica de Urinis." The recompence of his attachment to the cause of episcopacy and loyalty was the Sedleian professorship of natural philosophy at Oxford, conferred upon him after the Restoration, by the recommendation of archbishop Sheldon, soon after which he received the degree of doctor. Upon the establishment of the Royal Society, he was one of its first members. In the year 1664, when he is said to have discovered, and brought into use, the mineral water of Aftrop in Northamptonshire, he published his "Cerebri Anatome; cui accessit Nervorum Descriptio et Usus." This work, on which his reputation principally depends, was followed in 1667 by his "Pathologia Cerebri et Nervosi Generis, in qua agitur de Morbis convulsivis, et de Scorbuto." Before this year he was settled in London, and being nominated a physician in ordinary to the king, was advancing to the first rank in practice. His next publication was intitled "Adfectionum quæ dicuntur Hystericæ et Hypochondriacæ Pathologia Spasmodica, vindicata contra responsionem epistolarem Nath. Highmori. Cui accesserunt Exercitationes Medico-Physicæ de Sanguinis Accensione, et Motu musculari," 1670. On occasion of the loss of his wife, a daughter of dean Fell, he amused himself by writing his work "De Anima Brutorum quæ Homini Vitalis ac Sensitiva est; Exercitationes duæ," 1672, in which he considers the soul of brutes as the same with the vital principle in man, corporeal in its nature and perishing with the body. After his second marriage, he began to print in 1673 his "Pharmaceutice Rationalis, sive Diatriba de Medicamentorum Operationibus in Humano Corpore;" but he did not live to publish this work, as he was carried off by a pleurisy in 1675, at the premature age of 54, in the full vigour of his faculties and zenith of his reputation. Dr. Willis had no powers for appearing with advantage and brilliancy in society; but he was intent on science and practice, frugal, pious, and charitable. His works engaged great attention on their first publication; but in consequence of modern improvements, they have sunk in the public estimation, though they are not altogether neglected. They are written in a rich and elegant Latin style. Haller. Biog. Brit.

WILLIS, in *Geography*, a town of the state of New Jersey; 33 miles S.E. of Burlington.

WILLIS'S CREEK, a river of Virginia, which runs into James river, N. lat. 37° 40'. W. long. 78° 18'.

WILLIS'S ISLAND, a small island in the South Atlantic ocean, near the north-west coast of the island of Georgia, so named by captain Cook, from one of his crew who discovered it in the year 1775. S. lat. 54°. W. long. 38° 23'.

WILLISAU, a town of Switzerland, and capital of a bailiwick, in the canton of Lucerne; 15 miles W. of Lucerne.

WILLISTON, a post-town of the state of Vermont, in the county of Chittenden, with 1195 inhabitants; 25 miles N. of Newhaven.

WILLISTOWN, a township of Pennsylvania; 15 miles S.W. of Philadelphia.

WILLMAR, a town of the county of Henneberg; 7 miles S.E. of Meinungen.

WILLOBOCKE, a river of Yorkshire, which runs into the Swale.

WILLONGTALYS, a lake of Vermont. N. lat. $44^{\circ} 45'$. W. long. $71^{\circ} 58'$.

WILLOUGHBY, a town of England, in the county of Warwick, situated on a navigable canal, on the borders of Northamptonshire; 14 miles S.E. of Coventry.

WILLOUGHBY Bay, a bay on the south-east coast of the island of Antigua. N. lat. $17^{\circ} 10'$. W. long. $61^{\circ} 25'$.

WILLOUGHBY Lake, a lake of the state of Vermont.

WILLOW, &c., in *Botany*. See SALIX.

Our common willows in the spring season, when they are in flower, produce a quantity of cottony matter, which might be put to some use.

The Chinese are industrious enough to collect this cotton as it falls from their willows; and the women and children, among the poorer people, card it, and pick out the seeds, and render it fit for many uses in the place of cotton.

The poor people, in some part of the Indies, make a fort of liquor of the flowers of their willows before they are opened, which intoxicates them very suddenly; and the dry husks of the same tree remaining after the flowers and seeds are fallen, are wholesome as food, people in time of famine having lived upon them, boiled in water.

The wood of the willow, though in itself very light and spongy, is yet of a nature to bear the injuries of wet better than almost any other kind. It is used by the Chinese on this occasion, in the making of their wells, and on all other occasions where wood is to stand under water, and succeeds perfectly well. *Observ. sur les Coutumes de l'Asie*. For the uses to which willow-bark and wood are applied, see SALIX, and GUNPOWDER.

WILLOW, in *Agriculture*, a well-known tree, of which there are several different species or kinds; but those mostly cultivated for farm purposes are, the common white willow, the purple or red willow, the fallow, and the broad-leaved or Huntingdon willow.

The first is a tall-growing tree, of the deciduous kind. It has a fine silvery appearance in the leaves; is quick of growth, and the wood is very useful where lightness and cleanness of the grain is beneficial, as for hurdles, gates, hop-poles, &c.

The second is a free-shooting willow; but its wood is inferior for many uses, especially those of the farmer.

The third sort delights in a rather dry soil, being a tree below the middle growth. It has numerous branches, of a smooth appearance, and dark green colour. Its wood is very useful for hurdles and other similar purposes of the farmer.

It has two varieties, the long-leaved, and the striped fallow, both which are very useful.

The fourth sort, or red-hearted willow, is supposed by some as the best sort for planting, for the use of the farmer, as growing quickly; but the great use to which they are applied is that of making hurdles, stakes, gates, and farming implements, being a wood uncommonly tough and light, owing, as is conceived, to a new method used in planting them close to the ground. If it is the design of the planter to let them grow into timber, (which would be far superior to deal for the purpose of flooring, or other light work, particularly as it will neither splinter nor fire; and if suffered to remain for twenty or twenty-five years, would make good masts for small craft, as they shoot up perfectly straight, and without any collateral branches,) it is necessary, at the first or second year's growth, to observe which pole is the strongest, as the remaining poles must be cut away. In about fifteen years' time it is supposed they will want

thinning; of course the inferior must be taken out and the superior be suffered to remain.

In cultivating them on waste moist lands, laying out the ground into lands, like hop-lands, as from three to four yards wide, with a ditch on each side; three feet wide at the top, one foot at the bottom, and two and a half deep, is advised by a late writer as the best mode from much experience. The earth that comes out of the ditch should be thrown on the land. But if there is not fully sufficient fall for the water to get off, the ditch should be deeper and wider, till there is near a yard of earth above the level of the water. As soon as this is done, the ground must be double dug, that is, trenched two spades' depth, except it be very boggy, which will afford room for the plants to shoot, and will save the expence of weeding, which otherwise must be incurred in the first summer after the plants are set; for if they are not kept clear of weeds the first year, the hopes of the planter will certainly be destroyed.

In respect to the times of planting, they must be from January to the end of March; but the sets for that purpose should be cut from December to the end of February, when the sap is down. And the reason is, that if poles are cut in the spring (the sap being up), the stool will at least be weakened by bleeding, if not killed; and of course prevented from shooting so vigorously as if cut at the preceding time.

In regard to the sets or truncheons, they may be cut from twenty inches to two feet long; particular care should be taken in the cutting, that the bark be not fridged or bruised, or in any other respect injured; for in that case the plant will be weak and puny.

The poles have been sold at eight years' growth for 21*l.* per acre, net-money; the kids or brushwood pay for the felling. Had they been suffered to have stood two years longer, they would, it is said, have produced 30*l.* per acre.

The plantation of the basket and cooper's willow is an object of importance in those waste and neglected corners which are to be found upon every estate and farm.

The refuse dwarf willows or osal, as it is termed, are used in the fisheries and basket-work, and will pay, *communibus annis*, for the labour. The cooper's-willow differs from the common or basket-willow; the former is known by a single bud or eye throughout the rod, which simply throws out a leaf; the latter by a double or flattened eye, which produces a branch or sprig. The former is applicable to every purpose; the latter the cooper rejects: of course the former should be propagated.

Plantations of the willow kind have been vastly increased, indeed, in many parts of the country within these few years.

WILLOW-Galls, in *Natural History*, the name given by authors to certain protuberances found very frequently on the leaves of the several species of willow, which are properly galls, each containing the worm of a fly, and owing its existence to that insect.

The galls are usually of a roundish or oblong figure, and are equally protuberant on each side of the leaf: they are of a pale green at first; but they afterwards become yellowish, and finally reddish. The surface of these is seldom perfectly even, but usually has several little prominences and cavities in it. When this gall is opened, there is found in it a worm resembling a caterpillar in figure, having a smooth annulated body, a hard brown head, and twenty legs; and by Reaumur called false or bastard caterpillar. This creature, when the gall is young, is blue; it afterwards becomes greenish; and finally, when the gall becomes red, it is white. This insect seems to eat in its prison more voraciously than any

any other gall-insect whatever; for while the gall grows in size, it becomes also thinner in every part; so that the creature, at the proper time, has but little difficulty to get out. *Reaum. Hist. Insect. vol. vi. p. 211.*

When the time of the last change of this insect draws nigh, it leaves the tree, and descending to the earth makes its way into it in a proper place, and then becomes a nymph, out of which at a proper time issues a four-winged fly.

The flies which are produced in April copulate almost as soon as freed from their exuvia of the chrysalis state, and the females soon after lodge their eggs in the leaves of the willows. This is all done before the end of April, and the young ones hatched of these eggs live but a short time before they pass into the chrysalis state, and living flies are hatched from these in June. The young ones of this brood pass their chrysalis state in the earth, and appear not during the whole winter, till the spring sun enlivens them again. There is, beside these, another kind of galls of the willow-leaves, which are of the class of those, each of which contains several cells; in each cell of these there is found a small white maggot, the offspring of the egg of a two-winged fly, which, after passing the chrysalis state in the earth, also comes out in the form of its winged parent. The cells in the galls are different in number in the several galls, and are from four or five to twenty: they have no communication with one another, but each worm lives in its own cell.

Beside these there is also sometimes found in these galls a worm of a brownish-white colour, having two hooks in its head, and no legs at all. This has all the appearance of a carnivorous animal, and probably was deposited there in the egg-state by its parent, not to feed on the gall, but on its defenceless inhabitant. This worm finally becomes a small blueish beetle, and is often found alone in the cavity of the gall, often in company with its proper inhabitant, sucking its juices as it feeds on those of the plant. There seem to be several species of these devourers common to these galls; since Vallisnieri observed, in the boxes where he kept these galls to produce the animals from thence, many species of small beetles, and several distinct kinds of flies, which were probably the last state of several kinds of carnivorous worms, which had preyed upon the proper inhabitant of the galls. *Vallisnieri, Dialog. des Insect.*

WILLOW-Herb, or *French WILLOW*, in *Botany*. See *EPILOBIUM*.

WILLOW-Herb is a name sometimes given to the *lythrum* or purple loose-strife. See *LYTHRUM*.

WILLOW, Sweet, Dutch WILLOW, GALE, or Candle-Berry MYRTLE, in *Botany*. See *CANDLE-Berry-Tree*, and *Candle-Berry MYRTLE*.

WILLOW-Weed, in *Agriculture*, a term provincially applied to smart-weed, or *perficaria*, which is a troublesome weed on many places in the corn-fields and other tillage-lands. See *WEED*.

WILLS, in *Geography*, a town of Ohio, in the county of Guernsey, with 659 inhabitants.

WILLSBOROUGH, a post-township of Essex county, in New York, with a post-office, 530 miles from Washington, erected in 1788, then in Clinton county, and very extensive; from which several towns have been since erected. It is bounded N. by Chesterfield, E. by Lake Champlain, in the state of Vermont, S. by Essex, and W. by Lewis. Along the lake the land is level and tolerably productive. A small well-drain affords many scites for water-works; and iron-ore of the best quality is found in great abundance. The population consists of 668 persons, and the senatorial electors are 57. Here are, one distillery, a forge for making

bar-iron, an anchor-shop, a carding-machine, and a clothiery, besides a considerable number of grain and saw mills.

WILLSBOROUGH, a township of New York, near Crown Point.

WILLSTADT, a town of Sweden, in the province of Smaland; 50 miles W. of Wexio.—Also, a town of Germany, in the county of Hanau Lichtenberg; 7 miles S.E. of Straßburg.

WILLUGHBEIA, in *Botany*, was so named by Schreber, in memory of our great English naturalist, Francis Willughby, esq. of Middleton-hall, Warwickshire, the friend of RAY, in our biographical account of whom the reader will find many particulars relating to Mr. Willughby and his family. This gentleman may well claim botanical distinction, on account of his enquiries into the philosophy of vegetation, in conjunction with his illustrious associate, during the spring of 1669.—*Schreb. Gen. 162. Willd. Sp. Pl. v. 1. 1231. Mart. Mill. Dict. v. 4. (Amelania; Aubl. Guian. 265. Juss. 148. Lamarck Dict. v. 1. 125. Illustr. t. 169. Pacouria; Aubl. Guian. 268. Juss. 148. Lamarck Dict. v. 4. 691. Illustr. t. 169.)—Class and order, Pentandria Monogynia. Nat. Ord. Contortæ, Linn. Apocinea, Juss.*

Gen. Ch. Cal. Perianth inferior, of one leaf, fleshy, in five deep acute segments, very small. *Cor.* of one petal, valver-shaped: tube cylindrical, enlarged at the bottom: limb horizontal, in five deep, oblique, acute, wavy segments, more dilated at one side than the other, lying over each other at the base. *Stam.* Filaments five, very short, inserted into the tube just above the base; anthers arrow-shaped. *Pist.* Germen superior, roundish; style quadrangular; stigma capitate, ovate, thick, friated, double-pointed, subtended by a flat orbicular disk. *Peric.* Berry ovate, coated, of one or two cells. *Seeds* numerous, angular, compressed, imbedded in pulp.

Ess. Ch. Corolla valver-shaped, contorted. Stigma capitate. Berry coated, with many angular seeds.

1. *W. acida.* Acid Willughbeia. Willd. n. 1. (*Amelania acida*; Aubl. Guian. 266. t. 104.)—Stem erect. Flower-stalks the length of the footstalks.—Native of extensive forests in Guiana and Cayenne, bearing flowers and fruit in September. The trunk of this tree is seven or eight feet high, and seven or eight inches in diameter, with a greyish bark, and soft white wood. The head consists of very numerous, straight, knotty branches, subdivided in an opposite manner. Leaves opposite, on short stalks, elliptical, somewhat pointed, entire, wavy, smooth and shining, with one rib, and many transverse parallel veins; their greatest length seven inches, by three in breadth. Flowers axillary, three or four together on one common stalk, which is hardly so long as the adjoining footstalk. Bractæe scaly, solitary at the base of each general as well as partial stalk. Corolla whitish, scarcely so large as that of *Vinca minor*. Fruit lemon-coloured, oval, corrugated or warty, two inches long, separated by a longitudinal fleshy partition, into two cells, filled with acid viscid pulp, and containing many brown rough seeds. This fruit, though milky, is wholesome. After the rind is taken off, the remainder is soaked for a while in water. The flavour is agreeably acid, notwithstanding a great degree of viscidness, by which the pulp adheres to the lips and teeth. This fruit, with or without its rind, is preserved in sugar. In the latter state it is cooling, slightly acid; in the former moderately purgative, and esteemed useful in dysenteries. The whole plant when wounded discharges a milky, very tenacious, juice.

2. *W. scandens.* Climbing Willughbeia. Willd. n. 2. (*Pacouria guianensis*; Aubl. Guian. 269. t. 105.)—Stem twining. Flower-stalks branched, as long as the leaves.—Native

Native of woods about the mouth of the creek of the Galibis in Guiana, bearing flowers, as well as fruit, in May. The *trunk* is about three inches in diameter, sending off long, knotty, trailing *branches*, which twine round the neighbouring trees to their very fummits, from whence the extremities hang down, clothed with opposite, oval, smooth, entire *leaves*, not unlike the foregoing, and about as large, on short stalks; their rib, as well as lateral veins, are prominent and reddish. The *flower-stalks* are axillary, solitary, wavy, alternately branched, resembling tendrils, terminating in several little tufts, or umbels, of yellow *flowers*, rather smaller than the first species. *Fruit* roundish or obovate, the size and colour of a quince, of an agreeable scent when ripe, pulpy, yielding but a small quantity of milky juice if cut, though all the other parts of the plant contain a great quantity of the same kind of glutinous milk as the preceding. Aublet does not mention any use to which this species, or its *fruit*, is applied.

WILLUGHBY, FRANCIS, in *Biography*, was born in 1635 of a good family in Lincolnshire, and educated in Trinity college, Cambridge, under the tuition and in habits of friendly intercourse with the excellent philosopher and natural historian, John Ray. They were intimate associates, and made a foreign tour together in the years 1663 and 1664. To birds and fishes Willughby paid particular attention, and he formed a rich museum of animal and fossil productions. In 1668 he married the daughter of sir Henry Bernard, and his family residence at Middleton, in Warwickshire, was the place of Ray's frequent resort, where he and his host prosecuted their philosophical experiments and observations, the result of which they communicated to the Royal Society, of which they were both members. This instructive and pleasant intercourse was, however, prematurely interrupted by the death of Willughby in 1672, at the age of 37. His confidence in Mr. Ray was manifested by appointing him one of his executors, and committing to him the charge of educating his two infant sons, bequeathing to him an annuity for life as a compensation. Ray ascribes to him, without any trace of adulation, singular moral excellence and high mental endowments. His posthumous work, published under the inspection of Mr. Ray, was entitled "Francisci Willughbei Arm. Ornithologiae Libri tres; in quibus Aves omnes haecenus cognitae, in methodum naturis suis convenientem reductae, accuratè describuntur. Descriptiones iconibus elegantissimis et vivarum avium simillimis aeri incisus illustrantur. Totum Opus recognovit, digestit, supplevit Johannes Raus;" Lond. fol. This work was also translated into English by Ray, and published in 1671 with large additions. Mr. Ray also collected and arranged Willughby's papers on Ichthyology. He added the two first books, and with the assistance of the Royal Society published them in 1686 under the following title: "Fran. Willughbei Arm. de Historia Piscium, Libr. quatuor, jussu et sumptu Soc. Regiae Lond. editi. Totum Opus recognovit, coaptavit, supplevit librum etiam primum et secundum integros adjecit J. Raius." Oxon. fol. The papers of Willughby in the Phil. Transf. relate to vegetation, plants, and insects. The collection of Ray contains some of his letters. Biog. Brit. Pulteney's Sketches of Botany:

WILLY, in *Geography*, a river of England, which runs into the Avon, near Salisbury.

WILLYKA, a town of Lithuania, in the palatinate of Wilna; 60 miles E. of Wilna.

WILMANSTRAND. See VILMANSTRAND.

WILMANTON, a town of New York; 50 miles N. of New York.

WILMINGTON, a sea-port town of the state of Delaware, on Brandy-wine Creek; 22 miles S.W. of Philadelphia. N. lat. 39° 45'. W. long. 75° 34'.—Also, a sea-port town of North Carolina, with about 250 houses, on a branch of Cape Fear river. In January 1781, this town was taken by the British troops; 76 miles S.S.W. of Newbern, N. lat. 34° 11'. W. long. 78° 5'.—Also, an island near the coast of Georgia, at the mouth of the Savannah. N. lat. 32°. W. long. 81° 6'.—Also, a post-town of Vermont, on Deerfield river, in Windham county, with 1193 inhabitants; 10 miles E.S.E. of Bennington.—Also, a town of Massachusetts, in the county of Middlesex, with 716 inhabitants; 16 miles N. of Boston.—Also, a town of New York; 53 miles N. of New York.

WILMOT, JOHN, in *Biography*, earl of Rochester, was the son of Henry, earl of Rochester, an eminent loyalist in the reign of Charles I., and was born in 1647, at Ditchley, in Oxfordshire. In 1659 he was entered at Wadham college, Oxford, and afterwards travelled into France and Italy under a tutor, who is said to have reclaimed him from his early licentiousness; but upon his return to the profligate court of Charles II., in which he was a gentleman of the bed-chamber, he relapsed into his former intemperance. In 1665 he went to sea, and, as it is said, behaved with great intrepidity in the attack of a castle at Bergen, in Norway, which character for courage he also maintained when he afterwards served under sir Edward Spragge. In some of his domestic adventures, however, he forfeited this kind of reputation. Welcomed in all companies on account of his wit and vivacity, he became habitually intemperate, inasmuch that, on a subsequent review of his conduct, he acknowledged that for five successive years he was never free from the inflaming effects of wine. His various adventures, in his real, or in a disguised character, have furnished many anecdotes, that have been circulated in conversation, or in books of mere amusement, but which are not worth recording in graver publications. His wit furnished in the societies which he frequented a kind of apology for his profaneness and licentiousness; and as for his poetical compositions, they were for the most part lampoons or amatory effusions, the titles of which would stain the page of biography. "In all his works, (says Dr. Johnson, meaning probably those which *can be read*,) there is sprightliness and vigour, and every where may be found tokens of a mind which study might have carried to excellence." The justice of Walpole's sentence, in his "Catalogue of Noble Authors," will be generally allowed: "Lord Rochester's poems have much more obscenity than wit, more wit than poetry, more poetry than politeness." His course of debauchery was of no long duration; for soon after the age of 30 he sunk into a state of debility and disease, which induced him to study physic, and this study permitted him to reflect on the course of his past life, the irremediable effects of which he learnt from experience. Towards the close of his short life, he became acquainted with bishop Burnet, who convinced him of the truth both of natural and revealed religion, and his mind was then impressed to such a degree, that he is said to have become a sincere penitent. His life terminated in July, 1680, soon after he had commenced his 33d year. He left a son and two daughters. Biog. Brit. Johnson. Burnet.

WILMOT, in *Geography*, a town of Nova Scotia, near Annapolis.—Also, a town of New Hampshire, in the county of Hillsborough, with 298 inhabitants.

WILNA, a city and capital of the duchy of Lithuania, on the Wilia, founded in the year 1305. This city lies in a mountainous country, on several little eminences. It is

very large, and has two considerable suburbs, called Antokolla and Rudaiſzka. In the old ruinous royal palace is the arſenal, and the hall where the court of juſtice is held; and over-againſt it is the magnificent church belonging to the caſtle, which was built in the year 1386. The treaſury belonging to this church is very rich; and it is alſo remarkable for the elegant marble chapel of St. Caſimir, whoſe ſilver ſhrine is ſaid to weigh thirty quintals. There are upwards of forty churches in this city, and among theſe are, one Lutheran and one Calviniſt church, a Jewish ſynagogue, a Tartarian church, and a Greek church; but all the reſt are Popiſh churches. Not to mention the devaſtation which Wilna formerly ſuffered from the Ruſſians in the years 1610 and 1655, and from fire in 1737, it was deſtroyed by a dreadful conflagration in the year 1748, when 13 churches, the Jewish ſynagogue, 25 palaces, 469 ſtone edifices, conſiſting of private houſes, hoſpitals, inns, baths, convents, and mills, with 146 tradeſmen's ſhops, and diſpenſaries, beſides a great number of granaries and warehouſes, were conſumed to aſhes. In 1749 another fire happened by lightning, which conſumed 6 churches, the council-houſe, 8 palaces, and 277 other ſtone buildings. The chapel of St. Caſimir was alſo burned, and the loſs ſuſtained by the deſtruction of this edifice only amounted to a vaſt ſum. The churches have been ſince rebuilt at a very great expence, and ſome of them in a more elegant manner than before; but the city has not recovered its former grandeur. Wilna is the ſee of a biſhop, founded in 1387. The univerſity was founded in 1570. It gives name to a palatinate. In 1794 it was taken by the Ruſſians, and with its territory annexed to that empire; 168 miles E. of Königſberg. N. lat. 54° 36'. E. long. 25° 18'.

WILRE, a town of France, in the department of the Ourthe; 4 miles E. of Fauquemont.

WILS, a town of the county of Tyrol, on the borders of Bavaria; 5 miles N.N.W. of Reutten.

WILSCOW, a river of Brandenburg, which empties itſelf into a large lake, communicating with the Rega, 4 miles S. of Treptow.

WILSDEN, a townſhip of England, in the Weſt Riding of Yorkſhire, near Halifax.

WILSDRUF, or **WILSDORF**, a town of Saxony, in the margravate of Meiſſen; 9 miles W. of Dresden. N. lat. 51°. E. long. 13° 8'.

WILSELMAUR, a town of Auſtria; 3 miles W. of Brugg.

WILSNACH, a town of Brandenburg, in the Mark of Prignitz. This town was anciently famous, there being no leſs than three hoſts worſhipped at this place, which hoſts they ſay, in 1383, remained untouched in the church when it was burned down, and upon each of them was ſeen a drop of blood. To theſe hoſts numerous pilgrimages were made from the remotest countries; by which means this place roſe from a village to a ſmall town. At length the hoſts were burned in the year 1552, by the Lutheran preacher, Joachim Ellefeldt; 8 miles S. of Perleberg.

WILSON, **RICHARD**, in *Biography*, the moſt eminent landſcape-painter of the Engliſh ſchool, was the ſon of a clergyman, and was born at Pineges, in Montgomeryſhire, in 1714.

Having received from his father a good claſſical education, in the courſe of which he had evinced a decided diſpoſition for drawing, he was ſent to London at the age of 15, and placed as a diſciple with an obſcure portrait-painter, named Wright. After a lapſe of ſix years, he commenced profeſſor, and under the patronage of Dr. Hayter, biſhop of Norwich, he ſoon afterwards had the honour to paint

portraits of his preſent majeſty and his brother, the late duke of York; both at that time under the tuition of the biſhop. He continued to praſtiſe portrait-painting ſome time in London, but with no great ſucceſs, and at length went to Italy to cultivate his taſte. Even there he continued to praſtiſe it, ſtill unacquainted with the genuine bias of his genius, although occaſionally exerciſing his talents and employing his time in ſtudies of landſcape. At Venice Wilſon painted a portrait of the late Mr. Lock, of Norbury-park, one of the moſt creditable of his performances in that branch of the art; and it was there that accident opened his eyes to his own peculiar gratifications, and led him into that path, by purſuing which he has obtained a name among the wortheiſt in art.

As a matter of relaxation and amuſement, he had painted a landſcape, which being ſeen by Zuccarelli, ſo warmly excited that eminent artiſt's admiration, that he adviſed Wilſon to purſue that line of art excluſively. From this time it is believed that he abandoned portraiture, and followed the judicious advice of a rival artiſt; and ſoon after he left Venice in company with Mr. Lock, and travelling ſlowly to Rome, made numerous ſtudies on the way, which are ſtill preſerved at Norbury-park. On his arrival at Rome, the advice of Zuccarelli was confirmed by Vernet and Mengs, both then in high repute. So much were they delighted with Wilſon's landſcapes, that they each offered to exchange a picture with him; a propoſal far too flattering for reſuſal. This liberality, as commendable as it is unuſual, was followed by Vernet in the handſomeſt manner, as he hung the picture by the Engliſhman in his exhibition-room, and recommended him to the particular attention of the *cognoſcenti*.

His progreſs in landſcape-painting muſt have been very rapid; indeed it muſt have had the character of being almoſt intuitive, ſince he obtained a very great degree of reputation during his ſtay in Italy, and painted many pictures there of known celebrity. He travelled with the late earl of Dartmouth to Naples, and made a number of very fine drawings for that nobleman, now preſerved by his grandſon; and for him alſo he painted two pictures, one a very fine one, a view of Rome, which has been beautifully engraved by Middiman. He was alſo employed by the late duke of Bridgewater to paint a landſcape with the ſtory of Niobe; but his grace had the bad taſte to employ Placido Conſtanza to repaint the figures. To preſerve his reputation, Wilſon painted another of the ſame ſubject, and both are now in England. He returned from Italy in 1755, and occupied apartments over the north piazza of Covent-Garden. He had merited, and here he alſo obtained celebrity, and for a while employment. Many of his principal performances appear to have been painted about this time, moſt of which are known by the fine prints engraved from them by Woollett and others; in which the grandeur, breadth, and purity of compoſition in maſs and in line, contend for admiration with the talents conſpicuous in the engravings.

Hitherto the life of Wilſon was honoured as his talents deſerved; the remainder of it exhibited a gradual declenſion, not ſo much of power as of patronage. 'Tis true he was often too free in his pencil, and too much mannered in his ſtyle; repeating himſelf, perhaps, till it became irkſome: 'tis ſaid, alſo, that he was not of the moſt tractable humour, and was low in his purſuits and aſſociations. Whenceſoever it aroſe, he was doomed to undergo indifference and neglect, and conſequently the inconveniences of lowneſs of purſe. Sometimes he was employed to paint views of gentlemen's ſeats, but probably the occupation ſuited the artiſt as little as the reſult gratified the patron. Wilſon's view of nature was far too broad for ſuitable adaptation

adaptation to such a purpose, and consequently there are not many pictures of this class to be met with which have proceeded from his pencil. The great characteristic of his works is grandeur, resulting from breadth, purity, and simplicity, united in fullness of colour and mellowness of touch. He was perfectly original in feeling and execution, more grand in general conception than Claude, though infinitely less perfect in detail; and far from travelling through his career in art, with so even a pace as his great predecessor and only rival in the more exalted style of landscape-painting before our time. Now a third shines in the same hemisphere, and Claude and Wilson find no ill-fuited associate in the name of Turner.

At the institution of the Royal Academy, Wilson was chosen one of the founders; and after the death of Hayman he was made librarian. That station he retained till his death, which happened in May 1782, in the 68th year of his age.

WILSON, THOMAS, an English prelate, was born in 1663, at Burton-in-Wirral, Cheshire, and finished his education in Dublin college, where he took his degree of arts. In 1689 he was ordained priest, and in 1692 became domestic chaplain to the earl of Derby, and attended his son, lord Strange, who was his pupil, on a tour to the continent. Upon the death of the young gentleman, he returned to England, and in recompence of his faithful services, was nominated to the bishopric of the Isle of Man, by the earl of Derby, who then possessed the sovereignty of the island. The nomination was approved by king William, and he was consecrated in January 1697-8, having received at Lambeth the degree of LL.D. The revenue of the bishopric did not amount to more than 300*l.* a year; but by some collateral advantages the bishop was enabled to exercise hospitality and charity, to repair his ruined palace, and to found a new chapel at Castletown. He also established parochial libraries, which he furnished with religious books, among which was a small tract, the first that was ever printed in the Manks language. He improved the agriculture of the island by introducing into it corn, horses, cattle, and sheep, from England; and he studied physic with a view of administering to the relief and comfort of the islanders. He published ecclesiastical constitutions, which were so much approved, that lord chancellor King said of them, that "if the ancient discipline of the church were lost, it might be found in all its purity in the Isle of Man." Bishop Wilson, chiefly with a view to the interest of religion and morality, was anxious to maintain a due regard to episcopal authority, and this anxiety led him in two instances to exceed the bounds of prudence and propriety. When some copies of the "Independent Whig" had found their way into the island, he ordered them to be seized, apprehending that they inculcated sentiments hostile to Christianity and the established church. He also involved himself in difficulties and incurred reproach by excluding from the communion the wife of the governor, on account of an act of defamation, for which she refused to ask pardon of the injured party. This led to a serious altercation with the governor, who fined both the bishop and his two vicars-general, for suspending his chaplain for disobedience in admitting the wife to communion, and who arrested them for refusing to pay the fine. Accordingly they were kept close prisoners in the castle for nine weeks, till the bishop, by application to the council in England, obtained their release. The pious and mild-tempered bishop afterwards declined prosecuting the governor for damages. From his piety and attachment to the church, he was honoured in 1707 with the degree of D.D. from the university

of Oxford, in full convocation, and in which he was afterwards aggregated at Cambridge.

Such was the bishop's zeal for doing good, that he would not quit the sphere assigned him for this purpose, though he was offered an English bishopric; in reference to which circumstance queen Caroline, directing her attention to Wilson, among a number of other prelates who happened to be at court at the same time with him, said to them, "Here, my lords, comes a bishop whose errand is not to apply for a translation, nor would he part with his spouse because she is poor." His character was in such estimation with the French minister, that he procured an order that no French privateer should commit ravages on the Isle of Man. In this retired situation his life was prolonged to his 93d year, when he calmly expired in March, 1755, leaving one surviving son, known in the political world as rector of St. Stephen's, Walbrook, and patron of the celebrated historian Mrs. Macaulay. After his death a collection of his works was published in two vols. 4to. 1781. His notes to Crutwell's Bible, which was published under the bishop's name in three vols. 4to. 1785, are of little value. The translation of the New Testament into the Manks language, which he had undertaken, was completed by his successor, Dr. Mark Hillesey. Biog. Brit. Life prefixed to his Works. Gen. Biog.

WILSON, Dr. JOHN, a native of Feversham, in Kent, was a gentleman of Charles the First's chapel, and servant in ordinary to his majesty, in the character of chamber-musician. His instrument was the lute, upon which he is said to have excelled all the Englishmen of his time; and, according to Ant. Wood, his royal master was so pleased with his talents, and had even such a personal regard for him, that he not only listened to him with the greatest attention, but frequently condescended to lean or lay his hand on his shoulder, while he was playing.

For the excellence of his performance we must now wholly depend on tradition, as the compositions he has left behind him for the lute are but feeble testimonies of a great hand. Nor will his vocal productions, or Fantasias, either in print or manuscript, generate very exalted ideas of his genius or abilities as a composer. That he was admired by his majesty, and by the lovers of music at Oxford, where he was honoured with the degree of doctor in music, 1644, and where he long resided, proves more the low state of the art at this time, before the ears of the public were rendered discriminative, by a variety of great and rival talents, than his own perfections. Little had been heard, and but little was expected. Swift says, "we admire a little wit in a woman, as we do a few words spoke plain by a parrot:" and it might more seriously be said, that the best music, during times of ignorance and inexperience, is perhaps more admired than the most exquisite productions and performance of a more enlightened period. Nothing can prove this more clearly than the unbounded and hyperbolic praises bestowed in France on the operas of Lulli, of which, at present, the whole nation is ashamed.

Dr. Wilson, indeed, seems to have set words to music more clumsily than any composer of equal rank in the profession; but as he was respected by his contemporaries, and held an exalted rank in his art, a list shall here be inserted of his works; not so much for their intrinsic worth, as to enable curious enquirers to judge for themselves of the progress which music had made in this kingdom, when such productions were in high favour, not only with the greatest personages but principal professors of the times.

"Psalterium Carolinum, the devotions of his sacred ma-

jestly in his solitude and sufferings, rendered in verse, set to music for three voices and an organ or theorbo." Folio, 1657.

"Cheerful Aires or Ballads, first composed for one single voice, and since set for three voices." Oxon. 1660.

"Aires to a voice alone, to a theorbo or bafs viol;" these are printed in a collection entitled "Select Aires and Dialogues." Folio, 1653.

"Divine Services and Anthems," the words of which are in Clifford's Collection. Lond. 1663.

He also composed music to several of the odes of Horace, and to some select passages in Aufonius, Claudian, Petronius Arbitrator, and Statius; these were never published, but are preserved in a manuscript volume curiously bound in blue Turkey leather, with silver clasps, which the doctor presented to the university, with an injunction that no person should be permitted to peruse it till after his decease. It is still among the archives of the Bodleian library.

The compositions of Dr. Wilson will certainly not bear a severe scrutiny either as to genius or knowledge. It is, however, not easy to account for the ignorance in counterpoint which is discoverable in many lutenists of these times; for having harmony under their fingers, as much as the performers on keyed instruments, it facilitates their study, and should render them deeper contrapuntists than the generality of flute-players, whose flimsy compositions are proverbial.

On the surrender of the garrison of the city of Oxford, 1646, Dr. Wilson left the university, and was received into the family of sir William Walter, of Sarfden, in Oxfordshire; but, in 1656, he was constituted music-professor, and had lodging assigned him in Baliol college, where, being assisted by some of the royalists, he lived very comfortably, exciting in the university, according to A. Wood, such a love of music, as in a great measure accounts for that flourishing state in which it has long subsisted there, and for those numerous private music-meetings, of which this writer, in his own life, has given such an amusing relation. At the Restoration, Dr. Wilson was appointed chamber-musician to Charles II.; and, on the death of Henry Lawes, 1662, was again received into the chapel-royal, when, quitting the university, he resided constantly in London, till the time of his decease, at near 78 years of age, in 1673. Burney.

WILSON, in *Geography*, a town of South Carolina; 15 miles S.W. of Queenborough.—Also, a town of Scotland, in the county of Lanerk, founded in the latter end of the 18th century, by Messrs. Wilson of London, to accommodate the workmen employed in an iron foundry there; 5 miles E. of Lanerk.—Also, a county of West Tennessee, with 11,952 inhabitants, including 2297 slaves.

WILSONIA, in *Botany*, received that appellation from Mr. R. Brown, who commemorates by it the remarkable zeal and perseverance of Mr. John Wilson, an inhabitant of Kendal, Westmoreland, author of a "Synopsis of British Plants in Mr. Ray's Method," published at Newcastle-upon-Tyne in 1744. This work, however, is incomplete, the grasses, trees, shrubs, and all the cryptogamic tribe, except Ferns, being omitted. The author, whom Dr. Pulteney supposes to have died about the year 1750, is said to have left these classes finished in MS.; but they were never published. His performance indeed is now altogether obsolete, being chiefly translated from Ray and Tournefort; though with some alterations of the system of the former, and much additional matter, respecting the stations of rare plants; all which evinces a considerable portion of practical knowledge. Copious medical information is interspersed,

and a botanical dictionary is prefixed. But the botanist of whom we are speaking is principally worthy of memory, for that indefatigable love of science, which even the most humble situation, and the most limited circumstances, could not counteract. Whether he was employed in the manufacture of knitted stockings, formerly very extensive in his native town, or whether he made shoes, his biographers are not agreed; but he contrived to attain more knowledge, and cultivation of mind, than perhaps a great majority of the gentry around him. He must have had a competent acquaintance with Latin, and he may rank as an English writer among the most respectable, upon scientific subjects, in his time. We cannot commend his prudence, if we compassionate his difficulties, when he would have sold his only cow, the support of his wife and family, to buy a copy of Morison's work. But we may be allowed to regret that his mental application did not tend to so ample a pecuniary reward, as that of the famous sir Richard Arkwright, who repeatedly incurred the censure of many a prudent friend, for neglect of business, while he was planning a scheme of unbounded profit for himself and family. We rejoice to read that the book so much desired, was presented to Wilson by a benevolent lady, who lived near him, and who by this act has afforded a lasting testimony to the worth of his character. An honest man may always hope for indulgence and assistance, if he smoothes the path of hard duty with a little mental excursion, instead of mere unprofitable recreation or dissipation, whatever may be his situation in life. Many a cow has been sold in consequence of evil propensities; few have been sacrificed to procure food for the mind.—Brown Prodr. Nov. Holl. v. 1. 490. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Convolvuli*, Juss. *Convolvulaceæ*, Brown.

Ess. Ch. Calyx pitcher-shaped, five-sided, five-toothed. Corolla funnel-shaped, of one petal; imbricated in the bud. Germen with two seeds. Style cloven. Stigmas capitate. Capsule . . .

1. *W. humilis*. Humble Wiltonia. Br. n. 1.—Discovered by Mr. Brown, in the south part of New Holland. A little, dwarf, shrubby, prostrate, much branched, downy plant. *Leaves* small, sessile, thickish, imbricated in two ranks. *Flowers* axillary, solitary, sessile, without bractæas. Mr. Brown remarks, that the natural affinity of this genus must be uncertain while its fruit continues unknown. He met with the plant after the flowers were faded, before the seed-vesel was formed, nor is he certain whether the germen consisted of one cell, or of two. He ranges *Wiltonia* next after *Cressa*, of whose place in the natural system Linnæus had formed no opinion, but which Jussieu well refers to his *Convolvuli*, notwithstanding the solitary seed.

WILSONVILLE, in *Geography*, a town of Pennsylvania; 120 miles N. of Philadelphia.

WILSTER, a town of the duchy of Holstein, on the river of the same name; 8 miles N. of Gluckstadt.

WILSUM, a town of Germany, in the county of Bentheim; 11 miles W.N.W. of Nienhuus.

WILTER, a town of the Tyrolse, on the Inn; 3 miles above Inspruck.

WILTON, an ancient market, borough, and county-town of Wiltshire, England, derives its name from the river on which it was originally built. By old writers, it was called Wile, or Wily-Vilodunum and Ellandunum; and according to Baxter it was a chief seat of the British prince, Carvilius, and thence denominated Caer-Guilou. Henry of Huntingdon says, it afterwards became the capital of the West-Saxon dominions; but Leland and Dr. Milner contend,

tend, that Winchester was the chief town of that monarchy. It is not improbable that both places were at different periods possessed and occupied by the West-Saxon kings.

Antecedent to the Norman Conquest, Wilton was certainly a place of distinguished consequence. It contained several religious establishments; and was the principal town of the county, as appears from its having given name to the shire. Leland states, that it possessed twelve parish-churches at the period of Henry III.; a statement, if fully authenticated, would afford decided proof both of its great extent and population. The West-Saxon monarchs most probably had a palace here, and conferred on this place many marks of their royal favour. During their dynasty, Wilton was a royal borough, and appears to have been the scene of several important historical events. In 823, Egbert gave battle to and defeated the Mercian army near this town, which army was commanded by their king, Beornwulf. Several other engagements between the Saxons and Danes took place at and near Wilton. One of these occurred in 871, when the valiant Alfred commanded the Saxon army against a vast horde of the Danish marauders, who having plundered and laid waste several other places, were checked in their sanguinary career near this town, and after a desperate battle were compelled to petition for mercy and peace. Again in 1003, Wilton was visited by the Danes, when part of the town was consumed. During the civil warfare between king Stephen and the empress Maud, this place was the scene of much slaughter.

Wilton continued for many centuries after the Conquest celebrated for its monastic institutions, and particularly for its abbey. This was instituted in 773 by Wulfstan, earl of Wiltshire, who, having defeated Ethelmund, king of the Mercians, repaired "a certain old church of St. Mary, at Wilton, which had been destroyed by the Danes, and placed in it a college of secular priests." After the Conquest, king William and several of his successors added greatly to the opulence of this abbey, which was dissolved in the thirty-fifth year of Henry VIII. The other monastic institutions in this town were, a house of black friars, an hospital dedicated to St. Mary Magdalen, a collegiate church, and an hospital dedicated to St. John.

Wilton, though much decayed, still retains many of its ancient privileges. It is a borough both by prescription and by charter, and is governed by a corporation of its own, consisting of a mayor, recorder, five aldermen, three capital burgesses, and eleven common-councilmen, with a town-clerk, and other officers, as fixed by the last charter granted in the reign of Henry VIII. The town sends two members to parliament, and has regularly done so since the twenty-third year of Edward I. In 1710, it was agreed that the elective franchise was vested "in the mayor and burgesses, who are to do all corporate acts and receive the sacrament." The number of voters is stated at twenty-four in the History of Boroughs, where it is also observed, that "the election of any person to be a burgess of Wilton, who has not taken the sacrament of the Lord's supper, according to the rites of the church of England, within one year before such election, is a void election." The mayor is the returning officer; and the patron of the borough is the earl of Pembroke, whose seat is in the vicinity of the town.

The county courts of justice are sometimes held here; as are likewise the elections for the county members. The precise spot where the electors meet to choose their representatives, is marked by a large stone in the Warren, at a short distance south of the town. The market-days here

were formerly Wednesday and Friday in every week; but a small one on the former day is now only continued. The fairs are held on the 4th of May and the 12th of September.

The principal public buildings in this town are the parish-church and the town-hall. The other buildings here appropriated to public purposes are two chapels, one belonging to the Methodists, and another to the Independents, a free-school, and eight alms-houses. Wilton, including the borough and parish, contains, according to the parliamentary returns of 1811, 393 houses, and a population of 1963 persons. It was formerly celebrated for its carpet manufactories, which gave employment to a large proportion of its inhabitants. The first carpet made in England was manufactured at Wilton. Fancy woollens and flannels are now the only articles of manufacture. At the eastern end of the town is,

Wilton-house, seated in a fine park. This edifice is a large, extensive pile, erected at different periods, and displays different styles of architecture. It was formerly an abbey, but the alteration of Mr. James Wyatt has destroyed every monastic part of the building. This architect (now no more) was employed by the present noble proprietor, to enlarge the mansion and adapt it for the better display of its rich stores of ancient sculpture and paintings. A principal feature in this alteration is the formation of a glazed cloister, round a central court, which contains nearly the whole collection of statues, busts, basso-relievos, &c. Another considerable novelty is a large court-yard on the north, surrounded by offices, a lodge, and a new side to the house. The approach is through a triumphal arch, which is surmounted by a bold equestrian statue of Marcus Aurelius. A vestibule leads to the cloister, both of which are filled with ancient marbles.

The collection of works of art at Wilton-house has long been highly celebrated, and different publications have been given to the world, with catalogues and accounts of the various subjects. These are, the "Ædes Pembrochianæ," by Mr. Richardson, 12mo. 1774; an eleventh edition of which was published in 1788. Gambarini of Lucca published a "Description of the Earl of Pembroke's Pictures," in 1731. Kennedy also produced a "New Description of the Pictures, &c." in 1764. Another volume in 4to., with several engravings of the sculpture, was published in 1786. Wilton-house was formerly exhibited to strangers, but the present nobleman has shut it up. Several persons of the Pembroke family have been particularly distinguished in the annals of the country; particularly in Clarendon's history. Philip Massinger, an eminent dramatic poet, was probably born at Wilton-house, as his father lived in the service of the earl of Pembroke. See Giffard's Life and Works of Massinger.

About a mile east of Wilton is Bemerton, the living of which is possessed by the Rev. William Cox, author of several valuable works of History, Travels, and Topography. It is rather singular that the rectory of Bemerton has been enjoyed by several eminent literary characters, among whom we find the names of Walter Curle, bishop of Winchester, &c. George Herbert, (commonly called the divine Herbert,) and John Norris.—*Beauties of England, Wiltshire*, 8vo. 1814; by John Britton, F.S.A.

WILTON, a town of the district of Maine, in the county of Kennebeck, containing 770 inhabitants; 60 miles N.N.E. of Portland.—Also, a town of New Hampshire, in Hillsborough county, with 1017 inhabitants; 30 miles E. of Chesterfield.—Also, a town of Connecticut, in the county

of Fairfield, with 1728 inhabitants.—Alfo, a town of South Carolina; 27 miles S.W. of Charlestown.

WILTOWN, a town of South Carolina; 21 miles W.S.W. of Dorcheſter.

WILTPERG, a town of Auſtria; 8 miles S.W. of Freyſtadt.

WILTSHIRE, an inland county, ſituated towards the ſouth-ſiſtern diſiſion of England, derives its name from the town of Wilton, which, according to ſome ancient hiſtorians, was the metropolis of the Anglo-Saxon kingdom of Weſſex. On the north and north-weiſt it is bounded by Glouceſterſhire, on the ſouth-weiſt by Dorſetſhire, on the ſouth and eaſt by Hampſhire, and on the north-eaſt by the county of Berks. Theſe boundaries are in general artificial, and form a figure approaching that of an ellipſe. Concerning the extent and ſuperficial area of this county, various are the ſtatements of different writers. In the Magna Britannia it is ſaid to be thirty-nine miles in length from north to ſouth, and thirty in breadth from eaſt to weſt. Gough, in his additions to Camden's Britannia, eſtimates its length at forty-nine miles, and its breadth at thirty-ſeven. Its circumference, according to the ſame author, is one hundred and fifty miles, and the number of acres it contains 876,000. Mr. Davis, whoſe authority on this ſubject is highly reſpectable, in his Agricultural Report on the County, ſtates it to be in length fifty-four miles, and in breadth thirty-four. The ſame writer computes the ſuperficial area to be 1372 ſquare miles, or 878,000 acres.

The county of Wilts is a diſtrict peculiarly intereſting to the topographer and antiquary. To the latter, indeed, it offers a wider and more varied field for reſearch than perhaps any other county in England. The grand and myſterious monuments of Stonehenge and at Avebury, and the numerous barrows which cover its plains, are relics of an age anterior to hiſtorical record, and of which the annals of the world do not furniſh a parallel example. Like the proud pyramids of Egypt, the former were calculated by their conſtruction to have remained entire to almoſt endless futurity, if the agency of the elements had not been aſſiſted by the deſtructive influence of man. In the Wanſdyke, Bokerly-ditch, and Grimſditch, and in the ſimpler intrenchments with which the county abounds, we behold the remains of Britiſh towns, and perceive the mode adopted by the Britons to mark boundaries and form communications. The caſtles of Old Sarum, Scratchbury, Battlesbury, and Bratton, diſplay the efforts of a more advanced period; and many other of the Wiltſhire intrenched works bear marks of ſucceſſive occupation by the Romans, the romanized Britons, the Saxons, and the Danes. This part of the kingdom, indeed, ſeems to have been the principal theatre of the military and civil events which were conſequent on the Saxon and Daniſh invaſions. Here the far-famed Arthur and the ſtill more illuſtrious Alfred contended at different periods for the liberties of their country, and checked for a time the tide of invading conqueſt. At Ludgerſhall, Devizes, Malmsbury, and Marlborough, the veſtiges of Norman fortrefſes may yet be traced; and in Clarendon-park ſtood a ſumptuous palace, erected by king John. Malmsbury yet preſerves the ruins of a magnificent abbey; and in the cathedral of Saluſbury, we behold an edifice ſurpaſſing every ſimilar ancient ſtructure in uniformity of ſtyle and ſymmetry of parts. Many of the parochial churches in the county are alſo objects worthy the examination of the antiquary, as ſpecimens of architectural ſkill and ſcience; and in Wilton-houſe, Longford-caſtle, Font-hill, Corſham-houſe, Bowood, Tottenham-park, Charlton-park, Stour-

head, and Longleat, we are preſented with manſions alike celebrated for magnificence and beauty of ſcenery, and for popular attractions to the connoiſſeurs and artiſts of the country.

At the period of the invaſion of our iſland by Julius Cæſar, a people called the Belgæ inhabited a portion of this county. The Hedui are ſaid to have occupied its north-ſiſtern diſiſion, near the ſource of the Avon and about Cricklade. Another diſtrict is mentioned by Carte, in his Hiſtory of England, as being ſubſequentlly poſſeſſed by the Carvili, ſo named from their prince Carvilius; but whether theſe people were ſome of the Belgæ, or a diſtinct tribe, does not appear. Other authors ſuppoſe that the Cangi inhabited the northern parts, if not at this era, at leaſt ſoon after it.

When the Romans, after the lapſe of nearly a century, from the final departure of Cæſar, again invaded Britain in the reign of Claudius (A.D. 44.), they found the political condition and relations of its ſeveral tribes very materially altered. The opinion of Camden, in his Britannia, is, that the Belgæ had ſubdued the whole of Wiltſhire, and alſo had poſſeſſed themſelves of all the territories of the Hedui.

It is very generally admitted, that the Belgæ were the moſt powerful people in the ſouth-ſiſtern diſiſion of England at the era of which we are now ſpeaking; and no doubt is entertained of their having occupied all the ſouthern diſtrict of this county, as far as the Wanſdyke, which is therefore designated by the appellation of 'The great Belgic Boundary.'

Under the Romans, Wiltſhire formed part of Britannia-Prima, and many ſtations, encampments, and other military veſtigia of that people can be traced in different parts of it.

Subſequent to the departure of the Romans, the earlieſt event of political importance which occurs in hiſtory relating to Wiltſhire is the maſſacre of three hundred Britiſh nobles, on the ſpot where Stonehenge is ſituated, by the orders of Hengiſt (leader of the firſt Saxon expedition to England), who had invited them here to a banquet under the pretence of effecting a reconciliation between the Britons and himſelf. The truth of this dreadful catastrophe, however, is extremely doubtful, as it does not appear to be mentioned by any of the Saxon writers, and ſeems to reſt ſolely upon the authority of Nennius, and a few of the Britiſh or Welſh bards, who were evidently intereſted in the propagation of ſtories calculated to excite feelings of enmity and revenge in the breaſts of their countrymen, againſt a people, once their allies, but afterwards their inveterate and barbarous enemies. Carte ſays, that this "ſtory was borrowed from Witkind, who relates it of the Thuringians, who were murdered by the Saxons on a like occaſion, and upon a ſignal given in the ſame words made uſe of by the Britiſh writers." Turner, in his Hiſtory of the Anglo-Saxons, regards it as an incident which can neither be authenticated nor diſproved; and Whitaker, in his Hiſtory of Mancheſter, aſſerts, that the conqueſts of Hengiſt never extended beyond the limits of Kent; a circumſtance which, if fully eſtabliſhed, would no doubt tend to invalidate our belief of the tranſaction. Hume, in his Hiſtory of England, calls it a ſtory "invented by the Welſh authors, in order to palliate the weak reſiſtance made at firſt by their countrymen, and to account for the rapid progreſs and licentious deſtroyations of the Saxons." About the year 520, Cerdic, founder of Weſſex, having received conſiderable reinforcements from Saxony, and cut off a body of Britons which had been diſpatched to intercept them, collected all his diſpoſable forces, and advanced to Mount Badon, Badbury-caſtle, a Britiſh poſt

WILTSHIRE.

then considered of great strength and importance, on account of its commanding situation, and its proximity to the concurrence of the Roman roads, which intersect the north-eastern division of this county. The distinguished Arthur, who so long upheld the falling fortunes of his country, relieved the garrison with a large army formed under his own inspection: Cerdic, apprized of his intention, abandoned the siege, and waited the approach of the enemy. The conflict was severe; the genius of Arthur, however, ultimately prevailed over the superior science of the Saxon general, and the more steady conduct of his veteran troops. The subjugation of Wiltshire was not again attempted till the year 552, when warfare was once more renewed. Kenric, the son of Cerdic, and his successor in the West-Saxon monarchy, again passed the frontiers of his dominions, and threatened Sorbiodunum or Old Sarum.

The British army took a position to secure its safety, and fought with their usual intrepidity, but were defeated by the superior discipline of the Saxons. At "Baranbyrig," Barbury-castle, in the vicinity of Marlborough, another decisive battle was fought, in which the invaders were again the conquerors; and Wiltshire in consequence became incorporated in the kingdom of Wessex.

After several skirmishes, a decisive battle was fought at Wodnesbury, in which the usurper of Wessex was defeated. The Danes made a descent on the island in the thirty-second year of Egbert's reign, and effected great ravages in Wiltshire. King Alfred afterwards attacked the Danes near Wilton, and routed them; but elated by success, he incautiously suffered them to rally when they gained a victory.

Alfred engaged them in several battles with varied success, and ultimately compelled them to sue for peace, which was granted; yet in the following year, regardless of their recent engagements, they suddenly advanced to Chippenham, then a royal residence, and established themselves in that town. They had gained such considerable reinforcements, that the king, with a part of his army, retired into Somersetshire. Here he remained several months, occasionally falling out upon the enemy, destroying their magazines, and carrying off their provisions. Having mustered a considerable army, Alfred quitted his retirement, and advanced to Æthandune, where the Danish forces lay encamped, attacked them by surprise, and gained a complete victory. No other particular event occurred in Wiltshire until 976, when a synod was held at Calne, in which the respective rights of the regular and secular clergy underwent a solemn discussion: the secular clergy would not relinquish their pretensions; another council was, therefore, convened the same year at Amesbury, in which it appears the canons were unsuccessful.

The next historical occurrence in Wiltshire happened in 1003, when the towns of Wilton and Sarum were plundered and nearly burned to the ground by the Danish monarch.

In 1006 another army of Danes visited Wessex, and retiring to the coast through Wiltshire, when some of its natives attacked it in the vicinity of Kennet; the Saxons were, however, defeated, and purchased peace by submitting to the tribute called Danegelt.

England now remained tranquil five years, when in 1011 king Swein and his son Canute again landed on the south coast, and entering this county, levied heavy contributions on the inhabitants. King Edward at this time being indisposed at Corsham, his son Edmund took the field, and put the invaders to flight. An obstinate battle was fought, about this time, at "Scearstan," or Sherston, on the north-western verge of the county, by Edmund (who had just succeeded his father, Edward) against the Danes; the decision of the battle turned in favour of king Edmund by the

unexpected flight of Canute. Subsequent to the Norman Conquest, Wiltshire retained a considerable share of political interest.

In the year 1086, the conqueror held a great council at Sarum; "where," says Blackstone, "all the principal landholders submitted their lands to the yoke of military tenure, became the king's vassals, and did homage and fealty to his person." Thus was the feudal system formally introduced into this country.

Clarendon, in this county, is remarkable for the laws passed there in the reign of Henry II.; "whereby," says Blackstone, "the king checked the power of the pope and the clergy, and greatly narrowed the total exemption they claimed from the secular jurisdiction;" though the completion of his wishes was prevented by the murder of the proud and arrogant prelate, archbishop Becket. These laws are still familiar to the antiquary, by the appellation of the 'Constitutions of Clarendon.' At Marlborough, in 1267, Henry III. held a parliament, or a general assembly of the 'Estates of England,' to provide for "the better state of the realm, and the more speedy administration of justice;" and here were consequently enacted those statutes for the suppression of tumults, which have ever since been denominated, 'The Statutes of Marlbridge.' In the contests between the houses of York and Lancaster, the inhabitants of Wiltshire were conspicuous for their attachment to the fortunes of the Henries. Many of them were present at the battle of Tewksbury, an event which tended to fix the crown on the brows of Edward.

In the deplorable events of the 17th century, this county was equally distinguished. Many actions between the parliamentary and royal forces were decided within its boundaries; particularly at Malmesbury, at Ludgerhall, and at Round-a-way-hill, in the neighbourhood of Devizes. Wardour and Longford castles were alternately besieged and taken by both parties within one year.

The remains of antiquity in Wiltshire, first entitled to notice in a collective view, are the stupendous monuments at Avebury and Stonehenge, both of which are regarded as druidical temples. In these structures we are presented with the most wonderful works of a rude but powerful people; works in which the bodily strength of associated numbers, with the science and customs of their age, are strongly manifested, and which are calculated not only to excite the astonished gaze and amazement of the multitude, but also to rouse curiosity and awaken inquiry in the minds of antiquaries and historians. See AVEBURY, and STONEHENGE.

Next to these immense temples, because resembling them in relative magnitude, though totally dissimilar in kind, the Wanfdyke may properly claim attention. This vast earthwork, which is supposed to have originally intersected the whole country, is now only distinctly visible in detached places, throughout the range of hills to the south and west of Marlborough, where it still remains tolerably entire, and in one place is seen in a bold and connected line for the space of ten or twelve miles.

Barrows, or Tumuli.—Of corresponding antiquity to the monuments already named, are the artificial hillocks or mounds of earth which abound in this county, and which appear to have an intimate connection with those temples, as they are more numerous around Stonehenge and Avebury than in any other places. These memorials were undoubtedly appropriated to sepulchral purposes. By the researches of Mr. Cunnington, sir Richard C. Hoare's "Ancient Wiltshire," the Rev. James Douglas's "Nennia Britannia," and a few other enlightened antiquaries, we are
made

WILTSHIRE.

made familiar with the contents of these sacred depositories. See **BARROW**, and **TUMULI**.

The Roman stations mentioned in the Itinerary of Antoninus, as being situated within the county, are three in number, *Sorbiodunum*, *Verlucio*, and *Cunetio*. The first of these is placed by all antiquaries at Old Sarum; but the situation of the other two has been much disputed. Camden fixes *Verlucio* at Westbury; *Horley*, at Lackham; and *Stukeley*, whose opinion is the most probable, in the neighbourhood of Heddington. *Cunetio* was formerly supposed by some writers to be at the village of Kennet, and by others at the present town of Marlborough; but it is now generally allowed to have been situated at a short distance east from the latter place, near the north-eastern boundary of Savernake forest. Besides these, the Romans had several other settlements in this county; particularly at Easton-Grey, at Wanborough, at Pitmead near Heytesbury, and at Littlecot, at each of which places tessellated pavements and other Roman remains have been found. Of the Roman roads which passed through Wiltshire, the principal was a continuation of the *Julia Strata*, which entering the county from Bath, left it near Hungerford on the east. The Fosse road branched off from the *Julia Strata* at Bathford, at the north-west corner of the county, where in many places it is still conspicuous. Several other roads connected *Sorbiodunum* with neighbouring stations; and of these, three are traced with considerable certainty: first, one which led to *Durnovaria*, or Dorchester; secondly, that to *Venta-Belgarum*, Winchester; and thirdly, another to *Vindonum*, or Silchester.

The numerous encampments and other intrenched earthen works with which Wiltshire abounds vary not only in size and shape, but in method of construction and peculiarity of situation. Some of these are doubtless the works of the Britons, others of the Belgæ, of the Romans, of the Saxons, the Danes, and the Normans. Many of them, however, have been in all probability successively occupied and altered by the armies of one or more of these nations, at different periods subsequent to their original formation. The immense fortifications of Old Sarum, Chisbury-hill, near Warminster, and Vespasian's camp, near Amesbury, constitute the most distinguished monuments in this class of antiquities.

Castles.—That this county, at an early period, contained a number of those baronial fortified structures, which are usually designated by the term castles, and which are supposed by several writers to have been first introduced by the Normans, is undoubted. Most of them, however, are now totally demolished, so that it is even difficult to ascertain their actual sites; and the rest have been so much altered in later times, as almost to efface every vestige of the original building. The more celebrated of these edifices, and those which most frequently occur in the ancient historians, are the castles of Marlborough, Devizes, Ludgershall, Wardour, Combe, and Malmsbury.

General Aspect.—In a geographical arrangement, Wiltshire may be said to be naturally divided into two portions, by an irregular range of hills, which extends transversely through the greater part of the county in a direction inclining from the north-east to the south-west. These districts are usually denominated South and North Wiltshire, and differ very materially from each other, not only in appearance, but in almost every distinguishing quality.

South Wiltshire, which claims priority of notice on account of its superior extent, forms the western division of a vast tract of chalk-hills, which extends into Hampshire, and having for its boundaries the rich lands of Berkshire, and

the extreme verge of the Marlborough hills on the north; the broken ground of Somersetshire on the west; the new forest of Hampshire on the south; and the heaths of Surrey and Suffex, together with the West Downs of the latter county, on the east. The surface of the higher downs, to use the words of Gilpin, is "spread out like the ocean, but it is like the ocean after a storm; it is continually heaving in large swells." In some parts, the hills assume the form of rotund knolls, and are separated by smoothly-sided hollows, which vary considerably both in depth and extent. At other places they range along for a short distance in connected ridges, shewing on one side of the range rather a rapid declivity, from the top of which, on the other side, the hills sink in irregular gradation, till at length they frequently shelve into a perfect flat. This effect, says Marshall in his "Observations on" what he terms "the Western District" of chalk hills, is of course more particularly distinguishable, "where the range of hills is narrow, *single*, than where a congeries of such ranges are crowded together disorderly." The whole of this district, generally speaking, is separated into two divisions, the one called Marlborough-Downs, and the other Salisbury-Downs or Plain.

The principal valleys in this division of the county lie along the banks of the rivers, the most remarkable of which diverge like irregular radii from the country around Salisbury and Wilton. These display rich meadow and corn lands, interspersed with seats and villages, and finely covered in various parts with plantations of wood.

North Wiltshire differs entirely from the southern division of the county in its general appearance. Instead of a constant series of "chalky waves," the aspect of this district, which extends from the verge of the Downs to the hills of Gloucestershire, is nearly that of a perfect flat; the few deviations from the ordinary level being so gradual as scarcely to be perceptible, on a cursory view. The country here is so close and well wooded, that when viewed from any of the surrounding hills, it appears like one vast plantation of trees. If examined in detail, however, it is found also to contain many extensive tracts of rich pasture land, situated on the banks of the Lower Avon and the Thames, and of smaller streams which flow into both of those rivers.

Rivers.—Wiltshire abounds with rivers, which either take their rise within the county, or on its immediate confines. Two of these, the Thames and the Lower Avon, are unquestionably important streams. All the others are much inferior both in extent and consequence; but several of them deserve to be particularly noticed, *viz.* the Upper or Salisbury Avon, the Nadder, the Willey, the Bourne, and the Kennet. See **THAMES**.

The Lower Avon rises in the hilly district of North Wiltshire, at a short distance from the town of Wootton-Basset.

The Upper Avon is formed by the confluence of several smaller streams, which take their rise among the hills near the centre of the county. The Kennet rises near Avebury, and running in an easterly direction, unites with the Thames at Reading. The Willey and the Nadder join their streams at Wilton, and unite with the Avon at Salisbury.

The *cheese* of North Wiltshire has long been deservedly celebrated; though for some time after it became the staple commodity here, it was sold in the London market as the manufacture of Gloucestershire. See **CHEESE**.

Waste Lands.—It is a common idea that the Wiltshire downs consist entirely of "waste land." This notion, however, is completely erroneous; for if the correct appropriation of land is to be estimated by its comparative utility

WILTSHIRE.

in different conditions, the application of the grounds in the chalk district cannot be very easily improved, or materially altered for the better.

In North Wiltshire the number of common fields is very great, but none of them are of any considerable extent. It is subject of regret, however, that they should exist at all, as many of them are dispersed over the richest soil in the district; and if brought under regular cultivation would be extremely productive.

The chaces within Wiltshire are supposed to have been numerous formerly, but only three woodland districts now retain that peculiar appellation: these are Cranbourn-chace, Verditch-chace, and Albourn-chace. The first and second join each other, and occupy a long narrow tract of country on the southern confines of Wiltshire. There are three canals which intersect parts of this county: first, the Thames and Severn; secondly, the Kennet and Avon; and thirdly, the Wiltshire and Berkshire. See CANALS.

The *manufactures* of Wiltshire are various, and of great extent. Salisbury is noted for its flannels and fancy woollens; and besides carries on a considerable manufactory of cutlery and steel goods, which are probably superior in workmanship to any in the kingdom. Wilton was celebrated for a large manufactory of carpets, and Mere for another of fancy woollens; and in its neighbourhood a great quantity of linen is made, chiefly dowlas and bed-ticks. Broad cloths, kerseymeres, and fancy cloths, are the principal produce of the towns of Bradford, Trowbridge, Warminster, Westbury, Melksham, Chippenham, and all the adjacent towns and villages from Chippenham to Heytesbury. At Albourn is an excellent manufactory of cotton goods, of which fustians and thicksets form the most valuable portion. Swindon and its vicinity has been long famed for its manufactory of gloves.

Ecclesiastical and Civil Division and Government.—The whole of this county is situated in the province of Canterbury; and, with exception of the parish of Kingswood, is in the diocese of Salisbury. It comprehends two archdeaconries, Sarum and Wilts; the former comprising the deaneries of Salisbury, Amesbury, Chalk, Pottern, Wilton, and Wily; and the latter, with the annexed rectory of Minety, those of Avebury, Cricklade, Malmesbury, and Marlborough.

As in the other counties of England, the chief civil magistrates of Wiltshire are, the lord-lieutenant, the custos rotulorum, and the high sheriff; which last is elected annually, and whose official business is chiefly conducted by a deputy-sheriff. The other local members of government are, justices of the peace, mayors and bailiffs of boroughs, and a variety of subordinate officers. The acting magistrates are seventy-three, and the petty sessions for the county thirteen.

Wiltshire is comprehended in the western circuit, and sends thirty-four members to parliament, *viz.* two knights of the shire, two citizens for Salisbury, and two burgesses for each of the following boroughs; Chippenham, Calne, Cricklade, Devizes, Heytesbury, Hindon, Downton, Great Bedwin, Marlborough, Malmesbury, Ludgerhall, Westbury, Wilton, Wootton-Basset, and Old Sarum. At an early period the whole county was divided into twenty-nine portions, called *hundreds*; and these are again subdivided into two hundred and ninety-five smaller districts, called parishes; with parts of fourteen others. In the county is one city, Salisbury; and twenty-three market-towns, *viz.* Amesbury, Bradford, Calne, Chippenham, Cricklade, Devizes, Downton, Great Bedwin, Heytesbury, Hindon,

Ludgerhall, Malmesbury, Marlborough, Market-Lavington, Melksham, Mere, Swindon, Trowbridge, Warminster, Westbury, Wilton, and Wootton-Basset.

The government, provincial management, number, and state of the poor in this county, as laid before parliament in the year 1804, and published by authority of the house of commons, are detailed in the following particulars. It is stated, "that returns were received from three hundred and thirty-six parishes, or places, in the county of Wilts, in the year 1803; in 1785, the returns were from three hundred and thirty-six; and from three hundred and twenty-five, in 1776." It is then further stated, "that forty-one parishes, or places, maintain all or part of their poor in workhouses; the number of persons so maintained, during the year ending Easter 1803, was one thousand six hundred and seven; and the expence incurred therein amounted to 14,547*l.* 2*s.* 0½*d.*, being at the rate of 8*l.* 19*s.* 8*d.* for each person maintained in that manner. By the returns of 1776, there were forty workhouses capable of accommodating two thousand and seventy-nine persons. The number of persons relieved out of workhouses was forty thousand five hundred and eleven, besides four thousand five hundred and thirty-six, who were not parishioners. The expence incurred in the relief of the poor, not in workhouses, amounted to 113,888*l.* 17*s.* 9½*d.* A large proportion of those who were not parishioners appear to have been vagrants; and, therefore, it is probable the relief given to this class could not exceed 2*s.* each, amounting to 453*l.* 12*s.* 0*d.* This sum being deducted from the above 113,888*l.* 17*s.* 9½*d.*, leaves 113,435*l.* 5*s.* 9¼*d.*; being at the rate of 2*l.* 16*s.* 0*d.* for each parishioner relieved out of any workhouse. The number of persons relieved in and out of workhouses was forty-two thousand one hundred and twenty-eight, besides those who were not parishioners. Excluding the expence supposed to be incurred in the relief of this class of poor, all other expences relative to the maintenance of the poor amounted to 131,864*l.* 19*s.* 9¼*d.*, being at the rate of 3*l.* 2*s.* 7*d.* for each parishioner relieved. The resident population of the county of Wilts, in the year 1801, appears from the population abstract to have been one hundred eighty-five thousand one hundred and seven; so that the number of parishioners relieved from the poor's rate appears to be twenty-three in a hundred of the resident population. The number of persons belonging to Friendly Societies appears to be six in a hundred of the resident population. The amount of the whole total money raised by rates is 16*s.* 0¾*d.* per head on the population. The amount of the whole expenditure on account of the poor appears to average at 14*s.* 3½*d.* per head on the population. The expenditure in suits of law, removal of paupers, and expences of overseers, and other officers, according to the present abstract, amounts to 3682*l.* 15*s.* 0*d.* The amount of such expenditure, according to the returns of 1785, was then 2501*l.* 13*s.* 9*d.* The expenditure in purchasing materials for employing the poor, according to the present abstract, amounts to 849*l.* 8*s.* 7½*d.* The amount of such expenditure, according to the returns of 1785, was 434*l.* 11*s.* 9*d.* It does not appear from the returns received, that the poor of any parish or place in this county are farmed or maintained under contract. The poor of six parishes are maintained and employed under the regulations of special acts of parliament. Thirty-six Friendly Societies have been enrolled at the quarter-sessions of this county, pursuant to the act of 33 & 35 Geo. III."—*Beauties of England and Wales, Wiltshire*, by J. Britton, F.S.A. 8vo. 1814. *Ancient Wiltshire*, by sir Richard C. Hoare, bart., folio, 1815.

WILTSHIRE or *Eleven-shared Plough*, in *Agriculture*, an implement of this kind invented and used in that district. In Oxfordshire it is employed for many different purposes; as for cleaning the land, and with shares contrived for furrowing the land previous to sowing. The crops principally sown, or put in after the use of this implement, are those of tares or vetches and turnips. See PLOUGH.

WILZ, in *Geography*, a town of France, in the department of the Forests; 6 miles N.W. of Dicrich.

WILZBURG, a fort of Germany, in the principality of Anspach; 23 miles S.E. of Anspach.

WIMACOMACK, a town of New York, in Long island; 44 miles E. of New York.

WIMBA, or WINIPA, a town of Africa, on the Gold Coast; 20 miles S.W. of Acra.

WIMBLE, in *Rural Economy*, a term provincially made use of to signify a boring auger. See AUGER.

WIMBLETON, in *Geography*, a village of England, in the county of Surrey; supposed by Camden and others to be the place where Ethelbert king of Kent was defeated by Ceaulin king of the West Saxons. According to history, the battle was fought in the year 586, at Wibandune. At the south-west corner of Wimbledon common is a circular encampment, with a single ditch, containing a space of about seven acres; 9 miles S. of London.

WIMBORNE or WINBOURNE *Minster*, a market-town of remote antiquity, in the hundred of Badbury, Shafton division of the county of Dorset, England, is situated on the river Allen, near its confluence with the Stour, at the distance of 28 miles E.N.E. from Dorchester, and 100 miles S.W. by W. from London. It was called by the Romans *Vindogladia*, alluding to its situation on a river. The appellation of *Wimbourne* is Saxon, derived from *Bourne*, a vale, and *Wim*, a small river which flows near the town. The term *Minster*, from the church, was added to distinguish it from other places of the same name. Camden states this town to have been a place of great consequence in the Saxon times, and that it then retained many marks of Roman grandeur. The present appearance indicates no vestiges of its former prosperity: though large and populous, it has little to recommend it to notice; the streets being irregular, and the houses deficient in uniformity. The trade carried on is chiefly confined to the woollen manufactory and the knitting of hosiery. The great object whence *Wimborne* derived its ancient reputation, and to which it is solely indebted for its modern celebrity, is the Nunnery, which was founded among the earliest of its kind in the kingdom. It was erected, as *Leland* informs us, in the beginning of the eighth century, by *St. Cuthburga*, daughter of *Kenred*, and sister of *Ina*, king of the West Saxons. In the reign of *Edward the Confessor*, or of one of the *Edwards* his predecessors, this edifice having been destroyed by the Danes, the establishment was dissolved, and converted into a college of secular canons, consisting of a dean, four prebendaries, three vicars, and other inferior officers. This college subsisted till the year 1547: on the dissolution the revenues were vested in the crown. Great part of the lands was granted to *Edward*, duke of *Somerfet*; and part was by queen *Elizabeth* vested in the corporation of the college towards the foundation of a grammar-school. In the reign of *Charles I.* all the possessions of the church and school were granted, in trust, to twelve governors, who, among other conditions, were to find for the service of the collegiate church three priests, three clerks, and subordinate members. This establishment, with some temporary obstructions, has been kept up ever since. The revenues at present amount to between

three and four hundred pounds. The church merits particular notice for its age and venerable appearance, and for the peculiarities of its architecture. *Mr. Gilpin* says, its form dates its antiquity, being of the heaviest and earliest Saxon style. *Dr. Stukeley*, however, and other antiquaries, were of opinion, that the eastern tower, and most part of the church, were built soon after the Conquest. Many parts are of early Norman architecture, particularly the femicircular arches in the eastern tower, the false windows in the south transept, and several others. The church is cruciform, with two quadrangular towers, one standing on the middle of the roof, and the other at the west end; the former was anciently ornamented with a spire, said to be of an extraordinary height. The whole edifice consists of a chancel, nave, choir, and side aisles, a transept, and three porches. Its length, from east to west, is 180 feet. Both chancel and choir are supported by eight pillars, over which are five windows on the north and three on the south side. The nave is supported on each side by six massy pillars of an irregular form, above which are pointed arches, with zig-zag mouldings: the whole enlightened by a similar number of windows, apparently of a more modern style. Many royal and noble persons have been interred in this church, most of whom were anciently commemorated by suitable monuments. Of these time has destroyed many, and the hand of violence more. Among those remaining, the most conspicuous is that of king *Ethelred*, who, as the inscription states, was slain by the Danes April 23, 872. This tomb stands in the choir on the north side of the altar. On the opposite side is that of the duke and duchess of *Somerfet* (parents of *Margaret*, countess of *Richmond*, mother of *Henry VII.*), with their effigies in alabaster. Within this church were once standing ten altars for the celebration of divine service, all of which were composed of alabaster and other costly materials, and suitably ornamented. The furniture of the high altar was particularly splendid; consisting of a variety of crosses and images, and other objects of worship, of silver-gilt, and adorned with precious stones.

Exclusive of the church, the public buildings of *Wimborne* are few and uninteresting. The town-hall was suffered to fall to decay; near its site is an open space, called the Square. Here are two meeting-houses for Presbyterians and Anabaptists; and a large commodious workhouse. Two annual fairs are held, and a weekly market on Fridays. The north part of the town has been long styled a borough, and consists of two streets, *East Borough* and *West Borough* streets. It was never incorporated, but is governed by two bailiffs annually chosen. The south part of the town, including all that is not in the borough, composes the tything of *Wimborne Minster*. The population of the whole, by the return of the year 1811, was enumerated at 3158; the houses at 701. About a quarter of a mile from the town is an hospital, or alms-house, with a chapel adjoining, called *St. Margaret's* hospital. The time of its foundation is entirely unknown; but by several curious deeds preserved in the chapel, it appears to be at least as old as the time of king *John*, when it was set apart for the relief and support of poor persons afflicted with the leprosy. It does not appear to have had any endowment, but to have been supported by voluntary donations, for which pope *Innocent IV.*, in the year 1245, granted special indulgences. Since the year 1688, the alms-people are not required to have the original qualification of leprosy, but only to be poor aged people. A second hospital, or alms-house, was founded and endowed by *Gertrude Courtney*, marchioness of *Exeter*, for the maintenance of six poor men and women; and a patent

was procured from queen Elizabeth for incorporating the "governor and poor persons:" they were invested with a common seal and other corporate privileges. But notwithstanding this parade, the charity has dwindled to nearly nothing; the six persons now on the foundation having only each a room, and the poor pittance of fifty-two shillings yearly.—Hutchins's History of Dorsetshire. Beauties of England and Wales, vol. iv. Dorsetshire. By J. Britton and E. W. Brayley.

WIMBREL, in *Ornithology*, the English name of a bird of the curlew kind, the *scelopax phaeopus* of Linnæus, and known among authors by the name of *arquata minor*, or the lesser curlew, and called in the Venetian markets *taraniola*.

It is much of the shape of the common curlew, but is not more than half its size. Its beak is about three fingers' breadth long, dusky above and red below; its feet are greenish; the feathers on the head and neck brown tinged with red, marked in the middle with an oblong black spot; the upper part of the back, coverts of the wings, scapulars, and farthest quill-feathers, of the same colour with the neck, but the black spots spread out transversely on each web; the quill-feathers dusky, their shafts white, and their exterior webs marked with large femicircular white spots; the breast, belly, and lower part of the back, are white; the coverts of the tail are of a pale whitish-brown, crossed with black bars. Its haunts and food are much the same with those of the curlew, but it is much less frequent on our shores. Pennant.

WIMES, in *Geography*, a town of France, in the department of the straits of Calais; 9 miles S.S.W. of St. Omer.

WIMMERBY, a town of Sweden, in the province of Smaland; 62 miles N. of Calmar.

WIMMIS, a town of Switzerland, in the canton of Berne, on the Sibuen; 18 miles S. of Berne.

WIMPEL, of the Dutch *wimpel*, a muffler, a plaited linen cloth, which nuns wear to cover their necks and breasts. The word is also sometimes used for a streamer, or flag.

WIMPFEN, in *Geography*, a town of Germany, on the Neckar, near which it is joined by the Jaxt. This place consists properly of two towns, the most considerable of which is called Wimpfen-auf-dem-berg, or Wimpfen on the hill; and the other Wimpfen-in-thal, or Wimpfen in the vale. In the former of these are a Lutheran parish-church and a grammar-school, as also a Roman Catholic hospital; but in the latter is a Roman Catholic abbey, with a convent of monks. The magistrates here are wholly Lutherans. The Huns are said to have ravaged this town; but an instrument of donation by king Henry VII. bearing date in the year 1228, shews it to have entirely recovered from that calamity. On the failure of the dukes of Swabia, it gradually procured its freedom, and the emperors Charles IV. and Wenceslaus promised to maintain it in its immediate dependency on the empire. In the years 1645 and 1688, it was taken by the French. In 1802, it was given to the duchy of Baden; 8 miles N. of Heilbronn. N. lat. 49° 15'. E. long. 9° 15'.

WIN, at the beginning or end of the names of places, signifies that some great battle was fought, or a victory gained there. The word is formed from the Saxon *winnan*, to win, or overcome.

WINANDER MERE, or *Winder Mere*, in *Geography*, a lake of England, in the county of Westmoreland, in which is an island, with a village. This is one of the largest lakes in England, being 15 miles long, and two broad, and from 90 to 200 feet deep, well furnished with fish of several sorts, VOL. XXXVIII.

but especially char; 17 miles S.S.E. of Kewick, and 270 N.N.W. of London.

WINBERG. See WINTERBERG.

WINCANTON, or WINCAUNTON, a market-town in the hundred of Norton-Ferris, and county of Somerset, England, is situated on the western slope of a hill near the river Cale, at the distance of 108 miles W. by S. from London. It is a place of remote antiquity; and was probably occupied by the Romans, as numerous coins of that people were discovered here in the early part of the last century. The Saxons were long in possession of it; and it is recorded in Domesday-Book to have been held by one Elfi in the reign of Edward the Confessor; but when William came to the throne he gave it to Walter de Dowcri. It afterwards passed to the Lovels, lords of Castle Cary, and through the families of St. Maur and Zouch, till by attainder it passed to the crown, 1 Henry VII., who granted it to Giles, lord Daubery. The town, in its present state, consists of four principal streets. A fire which occurred in 1747 opened a way towards the improvement of the buildings. The turnpike-road from Taunton to Salisbury runs through it. A considerable market is held on Wednesdays for cheese, butter, pigs, and flax-yarn for the linen manufactures, which are chiefly those of dowlas and ticking, in which most of the poorer inhabitants find employment. Here are also three annual fairs. The town-hall is a respectable brick structure, with a rustic stone basement: here is likewise a small old market-house, with a few shambles. At the west end of the town, in the road to Castle Cary, is a stone bridge of two arches over the Cale: there is another of one arch over the same stream in the road to Bruton. Wincanton church is a spacious edifice, and consists of a nave, chancel, and two aisles. The church is ancient; but the chancel was rebuilt, and the church new-roofed and windowed in the year 1748. At the west end is a plain square tower. The parish extends nearly seven miles from north to south, and three miles from east to west: it includes, besides the town, five small hamlets. The population return of the year 1811 states the whole to contain 380 houses, and 1850 inhabitants. Within this parish, at the distance of about three miles north-east from the town, are the remains of the priory of Stavordale, founded in the reign of Henry III., by Richard Lovel, then lord of the manor, for canons of the order of St. Augustine. The priory is now converted into a farm-house and barn, in which several arches and other parts of the original structure still remain.—Collinson's History of Somersetshire, vol. iii. 4to. 1791.

WINCH, a popular term for a windlass.

WINCH also denotes the crooked handle for turning round wheels, grind-stones, &c.

WINCH, a small windlass, with an iron axis, hung in rhodings or gudgeons, abast some vessels' masts to hoist the main-sail, &c. with a conical piece of timber at each end without the cheeks. It is hove round by two iron handles, formed by cranks or winches, from whence it takes its name.

WINCHES, the large iron handles by which the main-pumps in ships are worked.

WINCH, used by rope-makers, is made of wood, having four spokes at each end, connected together by four blades, to form the body. Through the centre of the spokes is a hole to receive an iron bolt, on which it turns by a handle in one of the spokes. Its use is to wind the yarn on as it is spun.

WINCH, to twist or make spun-yarn with, is similar to the former, but much less. The motion given to this winch is by the hand in twirling the yarn: on the edges of the spokes is a small iron hook to stop the yarn in twirling,

after which the spun-yarn is wound round the body of the winch.

WINCHCOMBE, in *Geography*, a market-town in the lower division of the hundred of Kiftsgate, Gloucestershire, England, is situated on the Cotswold-hills, 15 miles N.E. by E. from the city of Gloucester, and 95 miles W.N.W. from London. It was anciently a town of considerable importance, was written Wincelcumbe in *Domesday-Book*, and was there styled a borough when only Gloucester and Bristol, in the same county, were dignified with that title. It was the scite of a castle, and of a mitred abbey sufficiently capacious for the reception of 300 monks; but every vestige of these buildings has long been levelled with the dust, and the places where they stood are only conjectured. By whom the castle was erected is unknown; but the abbey was founded in 798, by Kenulph, king of Mercia, and was consecrated with great solemnity in the presence of three kings, and a great number of prelates and nobles. Being destroyed by the Danes, it was rebuilt in 981 by Oswald, bishop of Worcester, who converted it into a college of seculars, and restored it to great splendour. It was largely endowed; and in the reign of the Conqueror nineteen manors in this county were annexed to it, independently of Winchcombe itself. In 1265 its abbot was summoned to parliament, and the privilege was continued to all the succeeding abbots. The twenty-eighth abbot, Richard Ancelme, surrendered his abbey and its possessions to Henry VIII. in 1539. The edifice was soon after totally destroyed. Tradition reports it as very magnificent; but no description of it is now extant. Winchcombe, with a small territory adjoining, is said to have been, in the Anglo-Saxon time, a sheriffdom or county of itself; but in the reign of Canute, it was divested of its independence, and annexed to Gloucestershire. The town now consists chiefly of two streets, intersecting each other; the houses are low, and principally of stone. The difficulty of approaching it, through the badness of the roads, has prevented it from being much visited; but the new turnpike-roads have now opened a short and easy communication. The church is a spacious structure, with a nave, chancel, two aisles, and an embattled tower: the body of the church is also ornamented with battlements and pinnacles. The old church stood at the west end of the town; but having fallen to decay, the present fabric was begun in the reign of Henry VI. by the abbot, William Winchcombe, who completed the east part: the remainder was finished by the parishioners, assisted by the munificence of Ralph Boteler, lord Sudeley. The government of the town, which is a borough by prescription, is vested in two bailiffs and ten assistants; from the latter, the bailiffs are annually chosen. A weekly market is held on Saturdays, and here are three annual fairs, which are well attended; but from the reclusive situation of the town very little trade is carried on, a paper-mill and a tan-yard being the chief sources of employ. The workhouse is an ancient irregular building, in which the poor are employed in spinning and weaving linen. Here are also an alms-house for twelve poor women, and three charity-schools. The population of the town in the year 1811, according to the return to parliament, was 1256, occupying 299 houses: the parish extends twelve miles in circumference, and includes nine hamlets; the enumeration of the whole was 461 houses, and 1936 inhabitants.

About a quarter of a mile to the south-east of the town are the ruins of Sudeley-castle, erected by Ralph, lord Boteler, an eminent statesman in the reign of Henry VI., on the scite of a more ancient castle which appears to have been the residence of Herald, son to Radulf, earl of Hereford, in the time of the Norman conqueror. In this family, which assumed

the name of Sudeley, the manor continued till the 41st of Edward III., when it was conveyed by marriage. Sudeley was attached to the crown till the reign of Edward VI. when it was granted to sir Thomas Seymour, who settled here with Catharine Parr, the queen-dowager, whom he had married, and who died here in child-bed, not without suspicion of poison. Seymour being afterwards attainted, Sudeley was granted to William Parr, marquis of Northampton, who forfeited it soon afterwards. It now belongs to the marquis of Buckingham. Of this once-famed fortress, very little remains: parts of towers, the hall, and the chapel, serve to shew the style of architecture and character of the buildings.—See Williams's *History, &c. of Sudeley Castle*, folio. Also *Beauties of England and Wales*, vol. v. by J. Britton and E.W. Brayley.

WINCHELSEA, a borough and market-town on the coast of Suffex, England, situated about 3 miles W. from Rye, 8 E. from Haltings, and 67 from London. It is a member of the Cinque Ports, and an incorporated town, the officers of which consist, according to its charters, of a mayor and twelve jurats; but these are seldom composed of more than four or five persons. Winchelsea is a place of antiquity; but by the ravages of the sea, the scites of its houses, at different periods, have totally changed. The epoch of the rapid though gradual overthrow of the original town is fixed by Leland between 1280 and 1287. During that time the inhabitants petitioned Edward I. for ground to found another town, who accordingly granted them the scite of the present town, which he surrounded with walls, and to it the inhabitants gradually removed. The new town afterwards fell into decay, from a cause just the reverse of that which ruined the old; for the sea deserted its neighbourhood, and left in its place a dreary marsh. This began to be sensibly felt in the end of the reign of queen Elizabeth. The channel leading to the harbour was choked, the coast was deserted, and the town, abandoned by the trader, soon declined. The houses and churches fell to ruin, so that a town, once covering a surface two miles in circuit, is now reduced to comparatively a few houses in a corner of its ancient scite, now a mile and a half from the sea. Of the ancient church, the lofty and spacious chancel, now used for divine service, and three aisles, alone remain entire. In it are two monuments, with effigies of knights templars. Some fragments of the walls and of three gates of the town still exist. From the situation of Winchelsea, and the spacious vaults frequently discovered, it is probable that the town was the principal mart for French wines, imported into England before the wine-trade with Portugal was established. Winchelsea sends two members to parliament, who are elected by about forty freemen. The houses in this parish, in 1811, were 126, containing 131 families, and 652 persons.—*Beauties of England*, vol. xiv. 8vo. 1813, Suffex, by F. Shoberl.

WINCHELSEA *Island*, an island in the Pacific ocean; 30 miles S.E. of sir Charles Hardy's island.

WINCHENDON, a town of the state of Massachusetts, in the county of Worcester, with 1173 inhabitants; 56 miles N.W. of Boston.

WINCHESTER, an ancient and eminent city in Hampshire, or the county of Southampton, in England, 11 miles N.N.E. from Southampton, and 62½ W.S.W. from London. The buildings are disposed on the eastern declivity of a low hill, which gently slopes to the valley of the river Itchen, the chalky cliffs of which, and the chalky soil of the surrounding heights, in the opinion of Camden, occasioned the ancient name of the city, *Caer-Gwent*, signifying the 'white city.' The latter portion of the name, under

WINCHESTER.

under the Romans, became *Venta*, with the addition of *Belgarum*, from its situation in the country occupied by the *Belgæ*, by which it was distinguished from *Venta Silurum*, now Caerwent, in Monmouthshire, and *Venta Icenorum*, now Caistor, near Norwich, in Norfolk. From *Gwent* or *Venta* we have the first part of the name, and *chester*, the last part, is a corruption of *castra*, the Roman term for encampments of different kinds; a frequent name, or appendage of a name, of various places in England, and perhaps invariably an indication that such places owe both their origin and their primitive form to the military stations of the earliest conquerors of Britain.

Historic Events.—The origin of Winchester, remote as it unquestionably is, has been carried back to an epoch far beyond belief, even a century and half anterior to the foundation of Rome. Without referring to such remote and uncertain time, we may safely infer that this spot was occupied by the Belgæ, a Germanic tribe, who passing from Gaul, took possession of the country bordering the southern coast of England. (Cæsar's *Bel. Gal.* ii. 4.) Previous to their occupancy, it is conjectured that Winchester was the *Caer-Gwent*, or white city, of the aboriginal Britons. After the Romans had subdued the Belgæ and the Britons, they took possession of this town, and fortified it with ramparts and walls. These were disposed on the sloping side of a hill, and in the usual form of a parallelogram. Within this inclosure the town was constructed and arranged; and from the importance of this station, and its connection with other stations by military roads, there can be little doubt that *Venta Belgarum*, the Roman name, was a place of considerable importance. Among the antique relics of the Romans, which have been discovered at Winchester, are several coins, urns, &c.; also some fine coins of Caractacus, called the first British emperor. After the Romans left the island in 446, Gortheryn, or Vortigern, was elected chief of the western district, and he fixed his seat of government at Winchester. This town, as well as the whole island, was soon destined to experience a total change of polity, customs, and manners, by the introduction and domination of the Saxons in 519. On this occasion, the name of the city was changed from the British *Caer-Gwent* and the Roman *Venta* to another of equal import, *Wintan-cestre*, from which the modern name, Winchester, has gradually been formed. In 635 an important event occurred in Winchester, the arrival there of Birinus, deputed by pope Honorius to preach the gospel in those parts of the country still involved in paganism. Favoured by king Kinegils, Birinus's apostolic labours were eminently successful; for the king founded a new cathedral on the site of that destroyed under Diocletian, which was consecrated under his son and successor, Kenewalch, in 648. Egbert, king of the West-Saxons, succeeding in the subjection of all the other Saxon princes, was in 827 crowned king of all England in the cathedral of Winchester, thus created or considered to be the metropolis of the whole kingdom; and there, about 854, Egbert's successor, Ethelwolf, granted his famous charter, establishing a general system of tythes. About this period the commerce of the city is recorded to have greatly increased, and the principal inhabitants are stated to have constituted a guild, under the royal protection; the earliest association of the kind, by a century, recorded in history. During the greater part of this and the succeeding reign, the see of Winchester was filled by the celebrated St. Swithun, by whose advice king Ethelbald raised fortifications for the defence of the cathedral against the Danes. Landing at Southampton, they advanced to Winchester, where they committed horrible

excesses; but the cathedral escaped their fury. About 871, however, that greatly suffered by them, and all the clergy belonging to it were massacred. On the ultimate success of the great Alfred, Winchester resumed a portion of its former splendour; it became again the seat of government; there the public records of the kingdom were deposited, in particular the general survey, called, from this circumstance, *Codex Wintoniensis*, afterwards imitated by William the Conqueror in 1086, in the famous Roll of Winchester, or *Domesday-book*. (See *DOMESDAY*.) The succession of Edgar the Peaceable increased the importance of Winchester. Among the judicious laws which he established was one to prevent frauds arising from the diversity of measures used in the country, by providing a standard legal measure for the whole of his dominions. This was the origin of the established *Winchester measures*; the standard vessels for measurement made by Edgar's orders being deposited in that city, where the original bushel is still preserved. In the reign of this prince, in 980, the cathedral, having been partly rebuilt, was solemnly re-consecrated. About the same time the married canons of the cathedral were, at the suggestion of St. Dunstan, removed, to make room for Benedictine monks. In Winchester, in 1002, and in the reign of Ethelred, furnished the Unready, commenced the general massacre of the Danes, in merciless vengeance for the atrocities they had committed on the inhabitants of the country. Thence arose the noted *bock-tide sports*, of which some traces may still be observed in remote corners of England. But this vengeance remained not long unrequited by Swayne the Dane, who obtained possession of Winchester eleven years afterwards. St. Elphage II., then bishop, is said to have first introduced organs into the cathedral. Canute, obtaining the sovereignty of England by the death of Edmund Ironside in 1016, chose Winchester for his capital, and, with other rich gifts, bestowed on the cathedral his crown, which was placed over the crucifix on the high altar: for Canute had vowed never more to wear that ensign of royalty, from the day when, by commanding in vain the flowing tide not to approach his feet, he proved to his flatterers the emptiness of their adulation, in hailing him lord of the ocean. Winchester cathedral is described to have been the scene of a legendary tale relating to queen Emma, mother of Edward the Confessor, who is said, but very improbably, there to have established the purity of her character, by walking unhurt over nine burning plough-shares. In the reign of the same Edward, the broad seal of the chancellor of England was first made and kept in Winchester.

The Norman invasion produced many changes in the state of the city: there king William I. founded a castle, as he did in many other parts of the kingdom, with the view of overawing, under the pretence of protecting, the inhabitants. It continued, however, to be a principal royal residence, although London then began to assume the pre-eminence. The politic monarch knew the influence of the clergy over the people; he consequently assigned all or most of the chief offices in England to his relatives, dependants, and offensive friends. Councils were held in Winchester, in which the new clergy, with the primate Lanfranc at their head, drew up canons or laws levelled at the Saxons, and framed to protect or justify themselves. Winchester, the residence of the court, was of course filled with the priests, the officers, and the followers of the king. The curfew (*couvre-feu*), or eight-o'clock-bell, was first rung in Winchester. The year 1079 is memorable in the history of Winchester, for then was commenced the present spacious and magnificent cathedral church. In the reign of Henry I. a singular

transaction is recorded to have taken place in Winchester. The current coin of the realm having been greatly debased by the different mint-masters, the king in 1125 assembled them in this city, when all, except three who dwelt in Winchester, were found guilty and severely punished. The base money was cried down, and an entirely new coinage ordered to be made by the three masters who had preserved their honesty. About the same period Henry caused to be made a standard yard, from the length of his own arm, in order to prevent frauds in the measurement of cloth. This standard is supposed to have been deposited with other measures, &c. in Winchester. The city suffered greatly in the dissensions consequent on the death of Henry, by the struggle between his nephew Stephen and his daughter, the empress Matilda, or Maud. Stephen's party held the bishop's palace, the cathedral, and adjoining quarters, while Maud's possessed the castle and the remainder of the city. By fire from Stephen's party, the whole north portion, then the most populous, the royal palace, the abbey of St. Mary, and twenty churches, the magnificent monastery of St. Gribald, the suburb of Hyde, &c. were destroyed. Many privileges were conferred on Winchester by Henry II., in particular, in 1184, that of being governed by a mayor, with a subordinate bailiff. His successor, Richard Cœur-de-lion, was solemnly re-crowned in the cathedral in 1194, on his return from captivity under the duke of Austria. In the end of 1207 was born in Winchester Henry III.; and soon afterwards his father John, for the sum of 200 marks paid at once, and 100 marks *per annum*, conferred on the city all the great and unprecedented privileges of a corporation. Thus Winchester became the first of all the corporate cities or towns in the kingdom, nearly two years before London had even obtained the privilege of being governed by a mayor. The dignity of the city was in some measure restored by the residence of Henry III. during his minority; but it again severely suffered in the contests between the king and the barons. A heavy blow on Winchester proceeded from the removal of the royal residence, in the reign of Edward I.; who nevertheless held several parliaments there. Under Edward III. it was constituted one of the fixed markets, or staples for wool; but by the removal of the staple in 1363, the decline of Winchester from commerce and wealth was sensible and uniform. In this reign the rebuilding of the nave of the cathedral was begun by bishop Edington; but the honour of completing it, with material alterations, was reserved for his celebrated successor, William of Wykeham. To Winchester Henry VI. was a considerable benefactor; for in his reign it was so reduced in trade and population, that the inhabitants, in a petition to the king, represented 997 houses to be unoccupied, and 17 churches shut up. The see of Winchester was held for a short time by cardinal Wolsey; but in the time of his successor, Gardiner, the final dissolution of the monasteries, and the consequent destruction of religious houses, reduced the city to be little more than the skeleton of what it had formerly been. It revived for a short time in the reign of Mary, who there solemnized her union with Philip of Spain, and restored to the see many lands which had been alienated by her father and brother. The city itself, however, had, as appears by a charter of Elizabeth, fallen "into great ruin, decay, and poverty." The commencement of 1603 was distinguished by the proclamation of James I. in Winchester, by the sole authority of the sheriff of the county, without waiting for the orders of the privy council in London, who had passed several hours in deliberation on the subject. In the civil wars of Charles I.'s time, Winchester was successively held by the

opposite parties; but after the fatal battle of Naseby in 1645, it was finally reduced by Cromwell. The works of the castle were blown up, the fortifications of the city were destroyed, together with the bishop's castle of Wolvesey, and several churches, and other public buildings. During the latter part of the reign of Charles II. Winchester had a prospect of recovering some portion of its former splendour; for he chose it for his usual residence, when not required by presence in the capital. In imitation of his example, many of the nobility and gentry likewise erected mansions in the city; but by Charles's death in 1685, the project was laid aside; the palace was left unfinished; and so completely has its original destination since been changed, that, after being frequently used as a prison of war, it is now converted into military barracks for the district.

Fortifications: Palace.—The ancient walls of Winchester form an irregular parallelogram, inclosing a portion of the slope of the western hill, and of the level valley watered by the Itchen. But the walls are now nearly destroyed, and the foss in many places filled up. The four gates seemed to have been constructed where those of the Roman intrenchment were opened. Through two of them, on the north and south sides, passed the great Roman road communicating between *Vindonum*, now Silchester, and *Clautentum*, near Southampton. Through the gate in the west side of the inclosure, corresponding to the Prætorian gate of the intrenchment, ran the road communicating with *Sorbiodunum*, where now stand the remains of Old Sarum. This gate still exists, but much altered from its ancient state: part of it is supposed to be coeval with the city walls, but the whole western face displays workmanship of much later date. The east or Decuman-gate opened access to the lively and wholesome waters of the Itchen.

The castle, now entirely destroyed, overlooking the city from the west, owes its origin to the system of dominion adopted by William of Normandy. Within its boundary, of an elliptic form, 850 feet from north to south, and in its greatest breadth 250 feet from west to east, stands the original chapel dedicated to St. Stephen, and apparently erected by the king of that name. It is in length 110 feet, divided into a nave and side-aisles. At the east end is suspended the antique curiosity called king Arthur's round-table; but with more accuracy attributed to king Stephen, and probably introduced by him to prevent disputes for precedence, during their entertainments, among the chivalrous champions of that age. It is 18 feet in diameter, composed of stout oaken planks, painted with the figure of the renowned Arthur, and the names of his twenty-four knights, as collected from the romances of the 14th and 15th centuries. The costume is, however, of the time of Henry VIII., when the table was painted. This chapel was, in Cromwell's time, converted into a county-hall, a destination to which it continues to be applied. In the year 1792, several thousands of French ecclesiastics sought refuge on the British shores. In their destitute situation, they were generously succoured by the state and the people; and at one time one thousand of them were accommodated with lodgings, and all other necessaries, in this deserted abode of royalty.

Winchester possessed also another fortress at the opposite end of the city: this was Wolvesey castle, the episcopal residence erected by the powerful bishop Henry de Blois, brother of king Stephen.

Cathedral.—The grand object of attraction in Winchester is its cathedral, one of the most interesting structures of its kind in England, whether considered with respect to the antiquity of its foundation, to the importance of the transactions

WINCHESTER.

actions of which it has been the scene, or to the characters of the personages whose mortal remains it contains. This magnificent and venerable structure has been called, and not without some propriety, a school of ecclesiastical architecture; for it displays to the student an interesting and varied series of examples of the ancient architecture of England, from an early age down to a recent period. If the student fail to satisfy himself as to Roman remains, or genuine Saxon work; if, after careful examination, he retire either doubtful or persuaded that no such architecture is there to be discovered; still he will have ample evidence and examples of Norman works. The plans and magnificent designs of those proud invaders and innovators are in that fabric amply displayed. There he will see that the Normans built not for themselves only, but for posterity; that their edifices were solid and substantial, simple in their forms, and large in their parts; that as their system of religion was intended to awe, terrify, and soothe the mind, so its primary temple in England was calculated most essentially to promote those ends.

The cathedral of Winchester is of great extent, its extreme external length being 556 feet, that of the cross or transepts 230 feet; the external breadth of the whole body and choir 118 feet, and that of the transepts 88 feet. The body of the church is divided by ranges of clustered columns into a nave and two side-aisles, as are also the transepts, with the unusual addition of aisles at the extremities. The great central tower rests upon four piers of great solidity, and rises 140 feet from the pavement. The present fabric may be considered as the foundation of bishop Walkelyn, a chaplain and relative of William of Normandy, who began it in 1079, constructing the crypts, the transepts, and tower; also the internal parts of the piers and walls of the nave. The work was continued under succeeding prelates, in particular by bishop de Lucy, who built part of the east end; by Edington, who erected the west front about 1330; and above all by Wykeham, who, between 1370 and 1400, brought the nave to completion. The exterior of the cathedral presents but few beauties, or attractive features. Its length of nave, plainness of masonry, shortness and solidity of tower, width of east end, and boldness of transepts, furnish, however, so many peculiar and specific characteristics. The interior of the cathedral will amply compensate for any defects or deficiencies of the outside. While the fine and sublime architecture of Wykeham, in the nave and aisles, produces the most impressive effect, and claims general admiration; the large, plain, and substantial works of Walkelyn, in the tower and transepts, are simply grand and imposing. The transepts and tower are entitled to attention, as unrivalled specimens of Norman architecture. The choir and eastern end are elevated above the nave and aisles, by an ascent of several steps; the choir itself occupying the space mostly beneath the Norman tower, and fitted up with stalls of elaborate workmanship. On the north side stands the pulpit, curiously carved in the time of Silkeste, who became prior in 1498. On the same side of the choir is placed the organ, in an unusual situation, under one of the lofty arches of the tower. The choir is separated from the nave by a screen of the Composite or Roman order of architecture, said to have been designed by Inigo Jones. The lofty stone screen erected behind the high altar is an elaborate and sumptuous work, covered with niches, canopies, buttresses, pinnacles, crockets, pediments, &c.; and when in its original colour and condition, with statues and costly ornaments, must have been peculiarly splendid and beautiful. On entering the church by the west door, the attention is first arrested by the vast and lofty

columns of the nave, which have been made to assimilate with the pointed style, by surrounding them with clustered shafts and other ornaments. Between the fifth and sixth columns, on the south side, stands the chantry or mortuary chapel, containing the tomb of bishop William of Wykeham, erected in his life-time, or prior to the close of the year 1404. On an altar-tomb within the chapel is the marble effigy of the founder. On the same side of the nave is the chantry of bishop Edington, who died in 1366; within an open screen is an altar-tomb supporting his effigy. Immediately behind the altar-screen in the south aisle is placed the sumptuous chantry of bishop Fox, containing neither tomb, statue, nor inscription, to commemorate the founder, or to explain his works in the church. In a recess beneath is the effigy of an emaciated human figure, the head ornamented with a mitre, but the feet resting on a skull. Opposite to this chantry in the north aisle stands that of bishop Gardiner, who died in 1555. Towards the eastern extremity of the church are the chantries of cardinal-bishop Beaufort on the south side, and of bishop Waynflete, the munificent founder of St. Mary's college, Winchester, and Magdalen college, Oxford, on the north side; each containing the tombs and figures of the respective prelates. The eastern extremity of the church is terminated by the spacious Lady-chapel, with a smaller inclosed on each side. In the middle of the presbytery, between the choir and the altar, lies a coffin-tomb, said to cover the remains of William Rufus, who was killed while hunting in the New Forest, and buried in this cathedral in 1100. On the top of the side-screens, between the present choir and the aisles, are placed six wooden chests, the work of bishop Fox, containing memorials and relics of Saxon monarchs, princes, and other illustrious personages, former protectors and benefactors of the cathedral. Another object of undoubted antiquity is the curious font, now placed between two columns on the north side of the nave. It is a large square block of black marble, charged on each side with sculptures, the whole supported by small columns at the corners. The subject of the sculptures is a matter of dispute; and although as productions of art they are beneath criticism, yet as representations of costume, manners, implements, &c. they deserve particular attention.

Episcopal Castle, or Palace.—Of this structure, better known by the name of Wolvesey castle, the ruins shew it to have been an imperfect parallelogram of about 250 feet by 160. What still remains belonged to the keep. Much was removed to make way for the new palace erected by bishop Morley, under the superintendance of sir Christopher Wren, after its destruction by Cromwell. The front of Morley's palace was pulled down by the present bishop, who never occupies the present house.

College.—One of the most celebrated institutions of Winchester is the college, founded by bishop Wykeham, and completed in 1393, on the site of an ancient grammar-school; intending it as preparatory for his establishment of New college, Oxford. The establishment in Winchester consists of a warden, 70 scholars, 10 secular priests, who are perpetual fellows, 3 priests' chaplains, 3 clerks, 16 choristers, and a first and a second master. So judicious and complete were the statutes drawn up by Wykeham for the government of his college in Winchester, as to be adopted, with very little alteration, by Henry VI., for his own splendid institutions at Eton and King's college, Cambridge. On the confirmation, by Edward VI., of the general dissolution of colleges, &c. introduced by his father, Winchester college, with those of Eton and the universities, were specially excepted. The buildings of the college occupy a considerable extent of ground, and consist principally

WINCHESTER.

cipally of two courts, with a cloister. The entrance to the first court is under a spacious gateway, having the mutilated busts of a bishop and a king, to represent the founder and his royal patron, Edward III. The second court is also entered by a tower gateway. The chapel and hall form the fourth wing of the quadrangle, and are enlightened by lofty windows. The interior of the chapel has a fine and lofty vaulting, ornamented with tracery. In the centre of the cloister is the library, originally constructed for a chantry in 1430, but converted to its present use in 1627. In the south-west corner of the second court is the hall or refectory, between which and the passage to the chapel is the school, a plain brick building, erected by subscription in 1687; over the door is the statue of the founder in bronze, by Cibber.

City.—The present city of Winchester consists chiefly of one main street, extending from the west to the east, with a number of collateral streets and lanes branching off on each side. Towards the middle of the High-street stands the city cross, an elegant specimen of the style of the age of Henry VI., consisting of three stories adorned with open arches, niches, pinnacles, and small crosses. The ecclesiastical buildings in Winchester, and its suburbs, were once very numerous, and, according to some writers, amounted to upwards of ninety. Scarcely twelve now remain. St. Laurence's church, near the cross, is considered as the mother-church of the city, and by a solemn entry into it the bishop takes possession of his see; but the principal parochial church is now that of St. Maurice. The town-hall, or more properly the hall of the guild of merchants of Winchester, rebuilt in 1713, occupies the place of one erected about 1112. There the city archives, the original Winchester bushel of king Edgar, and other measures of length and capacity fixed as standards by succeeding princes, and various curious memorials of antiquity, are now preserved. The front of the building is ornamented with a statue of queen Anne. A neat market-house was erected in 1772. The ancient building on the north side of the High-street, called St. John's House, was originally founded as an hospital, apparently so early as in the 10th century; but falling into the possession or the administration of the knights templars, or of St. John of Jerusalem, it was on the suppression of their order granted by Edward II. to a citizen of Winchester, who refounded the institution for the sick and lame soldiers, pilgrims, and wayfaring men, to have their lodging and diet there gratis for one night or longer, as their inability to travel might require. At the general dissolution of hospitals and monasteries, the revenues and moveable property were seized by Henry VIII.; but the corporation of the city reserved the building itself to be used for municipal business. In 1554 it again became a charitable foundation, being endowed by Richard Lamb, esq. for the support of six widows. The principal chamber or hall, which is 62 feet in length, 38 in breadth, and 28 in height, has been handsomely fitted up, chiefly by a donation from the late colonel Brydges of Avington. Among the decorations of this hall, in which public feasts, music-meetings, and assemblies are held, is a whole-length picture of Charles II. by Lely, presented to the city by that king himself. In the adjoining council-chamber are suspended the city tables, as they are called, containing a chronological arrangement of the most remarkable occurrences relating to Winchester. The ancient chapel of the hospital is now used as a free-school. The celebrated monastery founded by the great Alfred, called the 'Newen Mynstre,' and afterwards Hyde abbey, occupied nearly the whole space between the cathedral and the High-street. Completed under his son Edward, it was first filled by canons regular, who, in 963, gave place

to Benedictine monks. Alwyn, the eighth abbot, with twelve of his monks, fell in the battle of Hastings, in supporting the cause of his nephew, Harold, which drew upon the abbey the vengeance of William of Normandy. But the position being unhealthy and inconvenient, a new and magnificent church and monastery were erected just without the north wall of the city, on the spot called Hyde-meadow, to which the monks removed in 1110, carrying with them the remains of several illustrious personages who had been buried in the former abbey, among which were those of Alfred himself and some of his descendants. The annual revenues of Hyde abbey, of which the abbot sat in parliament, were at the dissolution valued at 865*l.* 18*s.* The church and monastery were soon afterwards demolished, and even the tombs of Alfred and other eminent persons were despoiled. What now remains of this institution is the small and mutilated parish-church of St. Bartholomew. Precisely on the space occupied by the abbey-church was some time ago erected a bridewell, or house of correction, on the plan of the benevolent Howard. In digging the foundations, stone coffins, rings, and vessels for the service of the church, were discovered, together with fragments of architectural sculpture. But between fifty and sixty years ago, among the remains of the buildings, was found a stone with this inscription in Saxon characters, 'Alfred Rex DCCCLXXXI.' Another remarkable religious establishment in Winchester was the Nunna Mynstre, or abbey of St. Mary, founded by Alfred's queen, Alswitha, and the place of her retirement after his death. Scarcely any vestige of the conventual buildings now remain, excepting in a modern mansion built out of the ancient materials, and the name of the abbey still applied to the inclosure where it stood.

Winchester, besides the numerous churches of the establishment, contains meeting-houses for dissenters of various denominations, among which the principal building is the Roman Catholic chapel, rebuilt by Dr. Milner in 1792, on the foundations of one more ancient. A large and commodious county-gaol, from the designs of Mr. Money penny, has been lately erected on the north side of the city.

Many privileges have at various times been bestowed on Winchester by English sovereigns. Its chief magistrate, as was before noticed, received the title of mayor in 1184, some years before the title was granted to the chief magistrate of London. The first charter was conferred by king John; but that under which the city is now governed was the gift of Elizabeth, "in consideration," as it is stated, "of the city of Winchester having been most famous for the celebration of the natiivities, coronations, sepulchres, and for the preservation of other famous monuments of the queen's progenitors." By this charter, the government is vested in a mayor, recorder, six aldermen, a town-clerk, two coroners, two constables, and a council of twenty-four of the "better, discreeter, and more honest sort" of inhabitants. The first return of representatives to parliament for Winchester took place in the twenty-third year of Edward I. The right of election is vested in the corporation.

Winchester possesses very little trade but what arises from its situation in the centre of an extensive and populous county. An ancient wool-combing manufactory, however, is still in existence, and of late years the silk manufacture has been introduced. All the public business of Hampshire is transacted in Winchester, which occasions a frequent and ample influx of strangers from all quarters. The cathedral and the college secure to the city the residence of a number of superior clergy. When in the height of its prosperity, and possessing the benefit of the wool-staple, the wealth of the inhabitants was greatly increased by the multitudes

tudes resorting to its fairs, the principal of which was held on the neighbouring hills of St. Giles and St. Mary Magdalen. St. Giles's fair was, at one time, by far the greatest in England. By a grant from William the Conqueror, it was originally to be held for one day only; but by Henry II. its duration was enlarged to sixteen days; and in that time no mercantile business was permitted to be transacted in Southampton, nor in any other place within seven leagues of St. Giles's hill. This fair has long become very insignificant; that of St. Mary Magdalen is still, however, much frequented. Since the year 1770, various improvements have been made in the general appearance of the city, by paving, repairing, and cleansing. As early as 1736 was established in Winchester an hospital or infirmary for the county, a very useful institution, conducted on a plan judicious in itself, and honourable to those entrusted with its administration. According to the parliamentary returns of 1811, the number of houses composing the city and suburbs was 1134, and the inhabitants 6705.

Hospital of St. Cross.—About a mile south from Winchester, in the valley watered by the Itchen, stands the venerable hospital of the holy cross; an institution still retaining more of its original character. "The lofty tower," observes Dr. Milner, "with the grated door and porter's lodge beneath it, the retired ambulatory, the separate cells, the common refectory, the venerable church, the flowing black drefs, and the silver crosses worn by the members, the conventual appellation 'brother' with which they address one another, the silence, the order, the neatness, in short, that reign here, seem to recall the idea of a monastery to those who have seen one, and will give no imperfect idea of such an establishment to those who have not had that advantage." But this establishment was never a monastery, being only an hospital originally founded by bishop Henry de Blois, between 1132 and 1136, for the residence and maintenance of thirteen poor men, and the relief of a hundred others of the most indigent of the city, but of creditable character. Each of these was to be provided daily with a loaf of bread, three quarts of small beer, and two messes for his dinner, in a hall appointed for the purpose. In the hospital was an endowment for a master, a steward, four chaplains, thirteen clerks, and seven choristers. Before the time of William of Wykeham, bishop of Winchester in 1366, the revenues of St. Cross had been employed in a way very different from the intentions of the founder; but that munificent prelate succeeded, after long litigation, in restoring the institution to its original uses, re-establishing it on a secure and well-ordered foundation. The plan was afterwards resumed and enlarged by cardinal-bishop Beaufort, for the additional support of two priests and thirty-five resident poor men: he also rebuilt a considerable portion of the hospital. The present establishment of St. Cross is but the wreck of its ancient institutions, having been severely sinned, though not quite destroyed, like many other charitable establishments, at the Reformation. Instead of seventy residents, clergy and laity, entirely supported in the place, and one hundred out-pensioners, the institution at present consists of but ten residing brethren, and three out-pensioners, with one chaplain and the master. Certain doles of bread, it is true, continue to be distributed to the poor of the neighbourhood; and, as perhaps the only vestige remaining in the kingdom of the simple hospitality of ancient days, the porter is daily furnished with a certain quantity of good bread and beer, of which every traveller, or other person whatever, who knocks at the lodge and calls for relief, is entitled to partake gratuitously. The buildings of the hospital once composed two courts; but the south side of the interior quadrangle

has been of late years pulled down. On the east side of the outer court is the 'hundred-menne's hall,' about forty feet long, now converted into a brewhouse; on the south side is the handsome tower-gateway, with the statue of the founder, Beaufort, in the upper part. In the second, or inner court, is the church, built in the cathedral form, with a nave and transepts, and a low massive tower at their intersection. The architecture of the edifice is singularly curious, as it throws some light on the progress, if not on the origin, of the pointed, or English style. The whole edifice seems to be a collection of architectural essays, with respect to the form and the disposition, of both the essential parts and the subordinate ornaments. It presents the ponderous pillar of a height equal to its circumference, but supporting an incipient pointed arch. The lower part of the nave contains massive Norman pillars; and the portal of the west front is an elegant specimen of the time of king John, or beginning of that of Henry III. The west wing of the remaining buildings contains the apartments of the Brethren, each of whom has for his own use three chambers and a separate garden. Adjoining to the hall on the north side are the apartments of the master, which are spacious and convenient; and on the east side is the ambulatory or open portico for exercise.

St. Catherine's Hill, or College Hill, separated from the meadows of St. Cross by the branches of the Itchen, is remarkable for the intrenchment carried round its summit: the former name it acquired from an ancient chapel on it, deprived of its endowments by cardinal Wolsey; the latter, because it is a frequent place of resort for the students of the college.

About three miles north-east from Winchester is Avington, anciently Abyngton, a seat and manor of the present marquis of Buckingham, in consequence of his marriage with the sole daughter and heiress of James, the last duke of Chandos. The manor, originally a royal demesne, was granted, in 961, by king Edgar to the monastery of St. Swithun, in Winchester; but in consequence of the dissolution, it became, in the reign of Elizabeth, the property of the ancient family of Bruges, or Brydges, first settled in Shropshire at the Conquest. Inter-marrying with the family of lord Chandos, renowned in the wars in France under Edward III., the honours of the two families have ever since continued united. Avington is situated in a secluded valley, well planted and nearly inclosed by high downs. The present mansion is mostly of brick, and has been greatly improved by the present possessor, having been previously dismantled by the late duke, for the purpose of adding two wings. Some of the apartments are fitted up with great elegance, and enriched by a selection of excellent paintings. The park formed by the late duke, about three miles in circumference, contains a piece of water supplied by the river Itchen.—History, &c. of Winchester, by the Rev. John Milner, D.D. F.S.A., 2 vols. 4to. 2d edit. 1809. Beauties of England, vol. vii. Hampshire, by J. Britton and E. W. Brayley. History, &c. of Winchester Cathedral, by J. Britton, 1 vol. 4to. with 30 Prints.

WINCHESTER, a town of New Hampshire, in the county of Cheshire, with 1478 inhabitants; 13 miles S.E. of Chesterfield.—Also, a town of the state of Connecticut, in Litchfield county, with 1466 inhabitants; 22 miles N.W. of Hartford.—Also, a town of the state of Kentucky, with 4 churches, and 2000 inhabitants.

WINCHESTER, or *Fredericktown*, a town of Virginia; 56 miles W.N.W. of Washington. N. lat. 39° 15'. W. long. 78° 22'.

WINCING, in the *Manege*, is said of a horse when he kicks, spurs, or throws out his hind feet.

WINCKHEIM, in *Geography*, a town of the duchy of Wurzburg; 4 miles N.N.W. of Lauringen.

WINCRANTUM, in *Natural History*, a name given by the people of the East Indies to a fossil substance resembling, in some degree, the plated lead ores of Europe, but containing very little of that metal; it is properly a species of blende, or mock-lead, of a talcky appearance; it is considerably hard, and is usually found in other stones. It is given in medicine in the Indies as a provocative to venery, being first calcined and beat to powder.

WIND, VENTUS, a sensible agitation of the air, by which a large quantity of it flows in a current or stream out of one place, or region, into another. See METEOROLOGY.

The winds are divided into *perennial*, *stated*, and *variable*.

They are also divided into *general* and *particular*.

WINDS, *Perennial* or *Constant*, are such as always blow the same way.

Of these we have a very notable one between the two tropics, blowing constantly from east to west; called the *general trade-wind*.

WINDS, *Stated* or *Periodical*, are such as constantly return at certain times. Such are the sea and land breezes, blowing from sea to land in the evening; and from land to sea in the morning.

Such also are the *shifting* or *particular* trade-winds, which, for certain months of the year, blow one way, and the rest of the year the contrary way. See *TRADE-Winds*.

WINDS, *Variable* or *Erratic*, are such as blow now this, now that way; and are now up, now hushed, without any rule or regularity, either as to time or place.

Such are all the winds observed in the inland parts of England, &c. though several of these claim their certain times of the day. Thus, the *west* wind is most frequent about noon; the *south* wind in the night; the *north* in the morning, &c.

WIND, *General*, is such a one, as at the same time blows the same way, over a very large tract of ground, almost all the year. Such only is the *general* trade-wind.

But even this has its interruption: for, 1. At land it is scarcely sensible at all, as being broken by the interposition of mountains, valleys, &c. 2. At sea, near the shore, it is disturbed by vapours, exhalations, and particular winds, blowing from landward; so that it is chiefly considered as *general*, only at mid-sea: where, 3. It is liable to be disturbed, by clouds driving from other quarters.

WINDS, *Particular*, include all others, excepting the *general* trade-winds; which see.

Those peculiar to one little canton, or part, are called *topical* or *provincial* winds. Such is the north wind, on the western side of the Alps, which does not blow above one or two leagues lengthwise, and much less in breadth: such also is the pontias in France, &c.

WINDS, *Physical Cause of*. Some philosophers, as Des Cartes, Rohault, &c. account for the general wind, from the diurnal rotation of the earth, and from this general wind derive all the particular ones. The atmosphere, say they, investing the earth, and moving round it; that part will perform its circuit soonest which has the smallest circle to describe: the air, therefore, near the equator, will require a somewhat longer time to perform its course in, from west to east, than that nearer the poles.

Thus, as the earth turns eastward, the particles of the air near the equinoctial, being exceedingly light, are left behind; so that, in respect of the earth's surface, they move eastwards, and become a constant easterly wind.

This opinion seems confirmed by this, that these winds

are found only between the tropics, in those parallels of latitude where the diurnal motion is swiftest. But the constant calms in the Atlantic sea near the equator, the westerly winds near the coast of Guinea, and the periodical westerly monsoons under the equator in the Indian seas, declare the insufficiency of this hypothesis.

Besides, the air, being kept close to the earth by the principle of gravity, would, in time, acquire the same degree of velocity that the earth's surface moves with, as well in respect of the diurnal rotation, as of the annual, about the sun, which is about thirty times swifter. See *TRADE-Winds*.

Dr. Halley, therefore, substitutes another cause, capable of producing a like constant effect, not liable to the same objections, but agreeable to the known properties of the elements of water and air, and the laws of the motion of fluid bodies. Such a one is the action of the sun's beams upon the air and water, as he passes every day over the ocean, considered together with the quality of the soil, and the situation of the adjoining continents.

According to the laws of statics, the air, which is less rarefied or expanded by heat, and consequently is more ponderous, must have a motion towards those parts of it which are more rarefied, and less ponderous, to bring it to an equilibrium; also, the presence of the sun continually shifting to the westward, that part towards which the air tends, by reason of the rarefaction made by his greatest meridian heat, is, with him, carried westward; and, consequently, the tendency of the whole body of the lower air is that way.

Thus a general easterly wind is formed, which being impressed upon the air of a vast ocean, the parts impel one the other, and so keep moving till the next return of the sun, by which so much of the motion as was lost is again restored; and thus the easterly wind is made perpetual.

From the same principle it follows, that this easterly wind should, on the north side of the equator, be to the northward of the east, and in south latitudes to the southward of it; for, near the line, the air is much more rarefied than at a greater distance from it; because the sun is twice in a year vertical there, and at no time distant above $23\frac{1}{2}$ degrees; at which distance, the heat, being as the sine of the angle of incidence, is but little short of that of the perpendicular ray; whereas under the tropics, though the sun stay longer vertical, yet he is a long time 47 degrees off, which is a kind of winter, in which the air so cools, as that the summer heat cannot warm it to the same degree with that under the equator. Wherefore, the air towards the north and south being less rarefied than that in the middle, it follows, that from both sides it ought to tend towards the equator.

This motion, compounded with the former easterly wind, accounts for all the phenomena of the general trade-winds, which, if the whole surface of the globe was sea, would undoubtedly blow quite round the world, as they are found to do in the Atlantic and the Ethiopic oceans. But seeing that so great continents do interpose, and break the continuity of the ocean, regard must be had to the nature of the soil, and the position of the high mountains, which are the two principal causes of the variations of the wind from the former general rule; for if a country lying near the sun prove to be flat, sandy, and low land, such as the deserts of Lybia are usually reported to be, the heat occasioned by the reflexions of the sun's beams, and the retention of it in the sand, is incredible to those who have not felt it; by which the air being exceedingly rarefied, it is necessary that the cooler and more dense air should run thitherwards, to restore the equilibrium. This is supposed to be the cause, why,
near

WIND.

near the coast of Guinea, the wind always sets in upon the land, blowing westerly instead of easterly, there being sufficient reason to believe that the inland parts of Africa are prodigiously hot, since the northern borders of it were so very intemperate, as to give the ancients cause to conclude that all beyond the tropics was uninhabitable by excess of heat.

Mr. Clare, in his *Motion of Fluids*, p. 302. mentions a familiar experiment, that serves to illustrate this matter, as well as the alternate course of land and sea breezes. Fill a large dish with cold water, and in the middle of it place a water-plate, filled with warm water: the first will represent the ocean, the other an island, rarefying the air above it. Then holding a wax-candle over the cold water, blow it out, and the smoke will be seen, in a still place, to move toward the warm plate, and rising over, it will point the course of the air (and also of vapour) from sea to land. And if the ambient water be warmed, and the plate filled with cold water, and the smoking wick of a candle held over the plate, the contrary will happen. (See BREEZE.) For the phenomena of the wind observed by Dr. Halley, and explained by his theory, see WIND, in *Navigation*.

From the same cause it happens, that there are so constant calms in that same part of the ocean, called the *rains*; for this tract being placed in the middle, between the westerly winds blowing on the coast of Guinea, and the easterly trade-winds blowing to the westward of it; the tendency of the air here is indifferent to either, and so stands in equilibrium between both; and the weight of the incumbent atmosphere being diminished by the continual contrary winds blowing from hence, is the reason that the air here holds not the copious vapour it receives, but lets it fall in so frequent rains.

But, as the cold and dense air, by reason of its greater gravity, presses upon the hot and rarefied, it is demonstrable that this latter must ascend in a continued stream as fast as it rarefies; and that, being ascended, it must disperse itself, to preserve the equilibrium; that is, by a contrary current, the upper air must move from those parts where the greatest heat is: so, by a kind of circulation, the north-east trade-wind below will be attended with a south-westerly wind above; and the south-east, with a north-west wind above.

That this is more than a bare conjecture, the almost instantaneous change of the wind to the opposite point, which is frequently found in passing the limits of the trade-winds, seems strongly to assure us; but that which above all confirms this hypothesis, is the phenomenon of the monsoons, by this means most easily solved, and without it hardly explicable. See MONSOONS.

Supposing, therefore, such a circulation as above, it is to be considered, that to the northward of the Indian ocean there is every where land, within the usual limits of the latitude of 30° ; viz. Arabia, Persia, India, &c. which, for the same reason as the Mediterranean parts of Africa, are subject to insufferable heats when the sun is to the north, passing nearly vertical; but yet are temperate enough when the sun is removed towards the other tropic, because of a ridge of mountains at some distance within the land, said to be frequently, in winter, covered with snow, over which the air, as it passes, must needs be much chilled. Hence it happens, that the air coming, according to the general rule, out of the north-east, to the Indian sea, is sometimes hotter, sometimes colder, than that which, by this circulation, is returned out of the south-west; and, by consequence, sometimes the under-current, or wind, is from the north-east, sometimes from the south-west.

That this has no other cause is clear from the times in
VOL. XXXVIII.

which these winds set, viz. in April; when the sun begins to warm these countries to the north, the south-west monsoons begin, and blow, during the heats, till October, when the sun being retired, and all things growing cooler northward, and the heat increasing to the south, the north-east winds enter, and blow all the winter till April again. And it is, undoubtedly, from the same principle, that to the southward of the equator, in part of the Indian ocean, the north-west winds succeed the south-east, when the sun draws near the tropic of Capricorn. Phil. Transact. N^o 183. or Abridg. vol. ii. p. 139.

Some philosophers, dissatisfied with Dr. Halley's theory above recited, or not thinking it sufficient for explaining the various phenomena of the wind, have had recourse to another cause, viz. the gravitation of the earth and its atmosphere towards the sun and moon, to which the tides are confessedly owing. See TIDES.

From the laws of universal attraction it has been inferred, that these celestial bodies must act upon the atmosphere, or that they must occasion a flux and reflux of the atmosphere, as well as of the ocean. Hence it has been alleged, that though we cannot discover aerial tides, of ebb or flow, by means of the barometer, because columns of air of unequal height, but different density, may have the same pressure or weight; yet the protuberance in the atmosphere, which is continually following the moon, must, they say, of course produce a motion in all parts, and so produce a wind more or less to every place, which, conspiring with or counteracted by the winds arising from other causes, makes them greater or less. Several dissertations to this purpose were published, on occasion of the subject proposed by the Academy of Sciences at Berlin, for the year 1746.

Although the atmospherical air is much more variable than water, and the action of the sun and moon upon it becomes much less apparent to us, because they must frequently concur with or be counteracted by the much more powerful effects of heat and cold, of dryness and moisture, of winds, &c. so that their action upon the barometer has been long disputed and even denied, (see MOON, *Influence of*;) yet that the moon in particular, as well as the sun, has such an action has been for a considerable time furnished; and of late years it has been in a degree observed and rendered sensible by means of very accurate and long-continued barometrical observations, and perceived only by taking a mean of the observations of many years.

Toaldo, the learned astronomer of Padua, after a variety of observations made in the course of several years, found reason to assert, that, *ceteris paribus*, at the time of the moon's apogee, the mercury in the barometer rises the 0.105 of an inch higher than at the perigee; that at the time of the quadratures, the mercury stands 0.008 of an inch higher than at the time of the syzygies; and that it stands 0.022 of an inch higher when the moon in each lunation comes nearest to our zenith, (meaning the zenith of Padua, where the observations were made,) than when it goes farthest from it. Journal des Sciences Utiles.

In the seventh volume of the Philosophical Magazine, there is a paper of L. Howard, esq. which contains several curious observations relative to this subject. This gentleman found, both from his own observations, and from an examination of the Meteorological Journal of the Royal Society, which is published annually in the Philosophical Transactions, that the moon had a manifest action upon the barometer. "It appears," he says, "to me evident, that the atmosphere is subject to a periodical change of gravity, by which the barometer, on a mean of ten years, is depressed at least one-tenth of an inch while the moon is passing from the
3 P quarters

quarters to the full and new; and elevated, in the same proportion, during the return to the quarter." A great fall of the barometer generally takes place before high tides, especially at the time of new or full moon.

The causes, it is said, which render the diurnal tide of the atmosphere insensible to us, may be the elasticity of the air, and the interference of the much more powerful effects of heat, cold, vapours, &c.

It has been calculated by D'Alembert, from the general theory of gravitation, that the influence of the sun and moon in their daily motions is sufficient to produce a continual east wind about the equator. So that, upon the whole, we may reckon three principal daily tides, *viz.* two arising from the attractions of the sun and moon, and the third from the heat of the sun alone: all which sometimes combine together, and form a prodigious tide.

In corroboration of the opinion of the influence of the sun, and principally of the moon, in the production of wind, we must likewise mention the observations of Bacon, Gassendi, Dampier, Halley, &c.; namely, that the periods of the year most likely to have high winds are the two equinoxes; that storms are more frequent at the time of new and full moon, especially those new and full moons which happen about the equinoxes; that, at periods otherwise calm, a small breeze takes place at the time of high water; and that a small movement in the atmosphere is generally perceived a short time after the noon and the midnight of each day.

M. Muschenbroeck, however, will not allow that the attraction of the moon is the cause of the general wind; because the east wind does not follow the motion of the moon about the earth; for in that case there would be more than twenty-four changes, to which it would be subject in the course of a year, instead of two. *Introd. ad Phil. Nat. vol. ii. p. 1102.*

Some action in the production of wind may also be derived from volcanoes, fermentations, evaporations, and especially from the condensation of vapours: for we find that, in rainy weather, a considerable wind frequently precedes the approach of every single cloud, and that the wind subsides as soon as the cloud has passed over our zenith.

Wherever any of the above-mentioned causes are constantly more predominant, as the heat of the sun within the tropics, there a certain direction of the wind is more constant; and where different causes interfere at different and irregular periods, as in those places which are considerably distant from the torrid zone, there the winds are more changeable and uncertain.

In short, whatever disturbs the equilibrium of the atmosphere, *viz.* the equal density or quantity of air at equal distances from the surface of the earth; whatever accumulates the air in one place, and diminishes it in other places, must occasion a wind both in disturbing and in restoring that equilibrium, as above stated.

Mr. Henry Eeles, apprehending that the sun's rarefying of the air cannot simply be the cause of all the regular and irregular motions which we find in the atmosphere, ascribes them to another cause, *viz.* the ascent and descent of vapour and exhalation, attended by the electrical fire or fluid; and on this principle he has endeavoured to explain at large the general phenomena of the weather and barometer. *Phil. Transf. vol. xlix. art. 25. p. 124.*

M. Briffon (*Principes de Physique*) also is of opinion that electricity is the principal and more general cause which produces winds; but Mr. Cavallo is of a different opinion.

After making various observations on the nature and theory of winds, Dr. Darwin recapitulates his opinions in the following manner. 1. The north-east wind consists of

air flowing from the north, where it seems to be occasionally produced; and has an apparent direction from the east, owing to its not having acquired in its journey the increasing velocity of the earth's surface. These winds are analogous to the trade-winds between the tropics, and frequently continue in the vernal months for four or six weeks together, with a high barometer, and fair and frosty weather. They sometimes consist of south-west air, which had passed by us or over us, driven back by a new accumulation of air in the north; and they continue but a day or two, and are attended with rain.

2. The south-west wind consists of air flowing from the south, and seems occasionally absorbed at its arrival to the more northern latitudes. It has a real direction from the west, owing to its not having lost in its journey the greater velocity it had acquired from the earth's surface from whence it came. These winds are analogous to the monsoons between the tropics, and frequently continue for four or six weeks together, with a low barometer, and rainy weather. They sometimes consist of north-east air, which had passed by us, and which becomes retrograde by a commencing deficiency of air in the north. These winds continue but a day or two, attended with severe frost, with a sinking barometer; their cold being increased by their expansion as they return into an incipient vacancy.

3. The north-west wind consists first of south-west winds which have been passed over, been bent down, and driven back towards the south by newly-generated northern air. They continue but a day or two, and are attended with rain or clouds. They consist of north-east winds bent down from the higher parts of the atmosphere, and having there acquired a greater velocity from the earth's surface are frosty and fair. They consist of north-east winds formed into a vertical eddy, not a spiral one, with frost or fair.

4. The north winds consist first of air flowing slowly from the north, so that they acquire the velocity of the earth's surface as they approach it; they are fair or frosty, but seldom occur. They consist of retrograde south winds; these continue but a day or two, are preceded by south-west winds, and are generally succeeded by north-east winds, cloudy or rainy weather, the barometer rising.

5. The south winds consist first of air slowly flowing from the south, losing their previous westerly velocity by the friction of the earth's surface as they approach it; they are moist, but seldom occur. They consist of retrograde north winds; these continue but a day or two, and are preceded by north-east winds, and are generally succeeded by south-west winds, colder, and the barometer sinking.

6. The east winds consist of air brought hastily from the north, and not impelled farther southward, owing to a sudden beginning absorption of air in the northern regions; they are very cold, the barometer high, and are generally succeeded by south-west winds.

7. The west winds consist of air brought hastily from the south, and checked from proceeding farther to the north, by a beginning production of air in the northern regions; they are warm and moist, and generally succeeded by north-east winds. They consist of air bent downwards from the higher regions of the atmosphere; if this air be from the south, and brought hastily, it becomes a wind of great velocity, moving perhaps 60 miles in an hour, and is warm and rainy: if it consists of northern air bent down it is of less velocity, and cooler.

Various other interesting remarks and reflections on winds may be seen in the notes to the Botanic Garden, by the same writer.

WIND.

The industry of some late writers having brought the theory of the production and motion of winds to somewhat of a mathematical demonstration; we shall here give it the reader in that form.

WINDS, Laws of the Production of. If the spring of the air be weakened in any place, more than in the adjoining places; a wind will blow through the place where the diminution is.

For, 1. Since the air endeavours, by its elastic force, to expand itself every way; if that force be less in one place than another, the effort of the more against the less elastic, will be greater than the effort of the latter against the former. The less elastic air, therefore, will resist with less force than it is urged by the more elastic: consequently, the less elastic will be driven out of its place, and the more elastic will succeed.

If, now, the excess of the spring of the more elastic above that of the less elastic air, be such as to occasion a little alteration in the baroscope; the motion both of the air expelled, and that which succeeds it, will become sensible, *i. e.* there will be a wind.

2. Hence, since the spring of the air increases, as the compressing weight increases, and compressed air is denser than air less compressed; all winds blow into rarer air, out of a place filled with a denser.

3. Wherefore, since a denser air is specifically heavier than a rarer; an extraordinary lightness of the air in any place must be attended with extraordinary winds or storms.

Now, an extraordinary fall of the mercury in the barometer, shewing an extraordinary lightness of the atmosphere, it is no wonder if that foretels storms. See **BAROMETER.**

4. If the air be suddenly condensed in any place, its spring will be suddenly diminished: hence, if this diminution be great enough to affect the barometer, there will a wind blow through the condensed air.

5. But since the air cannot be suddenly condensed, unless it have before been much rarefied, there will a wind blow through the air, as it cools, after having been violently heated.

6. In like manner, if air be suddenly rarefied, its spring is suddenly increased: wherefore, it will flow through the contiguous air, not acted on by the rarefying force. A wind, therefore, will blow out of a place, in which the air is suddenly rarefied; and on this principle, in all probability, it is, that,

7. Since the sun's power in rarefying the air is notorious, it must necessarily have a great influence on the generation of winds.

8. Most caves are found to emit wind, either more or less. M. Muschenbroeck has enumerated a variety of causes that produce winds, existing in the bowels of the earth, on its surface, in the atmosphere, and above it. See *Intr. ad Phil. Nat. vol. ii. p. 1116, &c.*

The rising and changing of the wind are determined experimentally, by means of weather-cocks, placed on the tops of houses, &c. But these only indicate what passes about their own height, or near the surface of the earth: Wolfius assures us, from observations of several years, that the higher winds, which drive the clouds, are different from the lower ones, which move the weather-cocks. And Dr. Derham observes something not unlike this. *Phys. Theol. lib. i. cap. 2.*

The author last-mentioned relates, upon comparing several series of observations made of the winds in divers countries; *viz.* England, Ireland, Switzerland, Italy, France, New England, &c. that the winds in those several places seldom agree; but when they do, it is com-

monly when they are strong, and of long continuance in the same quarter; and more, he thinks, in the northerly and easterly than in other points. Also, that a strong wind in one place is oftentimes a weak one in another, or moderate, according as the places are nearer, or more remote. *Phil. Transf. No 267 and 321.*

WIND, Laws of the Force and Velocity of. Wind being only air in motion, and air being a fluid subject to the laws of other fluids, its force may be regularly brought to a precise computation: thus, "The ratio of the specific gravity of any other fluid to that of air, together with the space that fluid, impelled by the pressure of the air, moves in any given time, being given; we can determine the space through which the air itself, acted on by the same force, will move in the same time." By this rule:

1. As the specific gravity of air is to that of any other fluid; so, reciprocally, is the square of the space, which that fluid, impelled by any force, moves in any given time, to the square of the space which the air, by the same impulse, will move in the same time.

Supposing, therefore, the ratio of the specific gravity of

that other fluid to that of air, to be $= \frac{b}{c}$; the space de-

scribed by the fluid to be called s ; and that which the air will describe by the same impulse, x . The rule gives

$$\text{us } x = \sqrt{\frac{b s^2}{c}}$$

Hence, if we suppose water impelled by the given force, to move two feet in a second of time, then will $s = 2$; and since the specific gravity of water to the air is as 800 to 1, we shall have $b = 800$, and $c = 1$; consequently, $x = \sqrt{800 \times 4} = \sqrt{3200} = 57$ feet nearly. The velocity of the wind, therefore, to that of water, moved by the same power, will be as 57 to 2; *i. e.* if water move two feet in a second, the wind will fly 57 feet.

2. Add, that $s = \sqrt{\frac{c x^2}{b}}$; and therefore the space

any fluid, impelled by any impression, moves in any time, is determined, by finding a fourth proportional to the two numbers that express the ratio of the specific gravities of the two fluids, and the square of the space the wind moves in, in the given time. The square root of that fourth proportional is the space required.

Mr. Mariotte, *e. gr.* found, by various experiments, that a pretty strong wind moves 24 feet in a second of time, which is at the rate of 1440 in a minute; *i. e.* at the rate of somewhat more than 16 miles in an hour: wherefore, if the space which the water, acted on by the same force as the air, will describe in the same time, be required; then will $c = 1$, $x = 24$, $b = 800$; and we shall find $s =$

$$\sqrt{\frac{576}{800}} = \frac{24}{\sqrt{800}} \text{ nearly.}$$

Derham estimated the velocity of the wind in very great storms at 66 feet *per* second; and de la Condamine at 90½ feet *per* second.

3. "The velocity of wind being given, to determine the pressure required to produce that velocity;" we have this rule. The space the wind moves in one second of time, is to the height a fluid is to be raised in an empty tube, in order to have a pressure capable of producing that velocity, in a ratio compounded of the specific gravity of the fluid to that of the air, and of quadruple the

WIND.

altitude a body descends in the first second of time, to the aforesaid space of the air.

Suppose, *e. gr.* the space through which the air moves in a second, $a = 24$ feet, or 288 inches; call the altitude of the fluid x ; and the ratio of mercury to air,

$$\frac{b}{c} = \frac{800 \times 14}{1} = \frac{11200}{1};$$

and the altitude through which a body descends in the first second of time, 16 feet 1 inch; then, by the theorem, we shall have $288 : x ::$

$$11200 \times 762 : 288, \text{ and consequently } x = \frac{288 \times 288}{11200 \times 762}$$

$= .01$, &c. of an inch. Hence we see why a small but sudden change in the barometer is followed with violent winds. See an account of the principle upon which these calculations are founded under the article WATER.

When the direction of the wind is not perpendicular, but oblique to the surface of the solid, then the force of the former upon the latter will not be so great as when the impulse is direct, and that for reasons which are easily derived from the theory of the resolution and composition of forces, and from the theory of direct and oblique impulses. In short, the general proposition for compound impulses is, that the effective impulse is as the surface, as the square of the air's velocity, as the square of the sine of the angle of incidence, and as the sine of the obliquity of the solid's motion to the direction of the impulse, jointly; for the alteration of every one of those quantities will alter the effect in the same proportion. But these general rules, as we have already more than once observed, are subject to great variations; so that their results seldom coincide with those of actual experiments.

Philosophers have used various methods for determining the velocity of the wind, which is very different at different times. The method used by Dr. Derham was that of letting light downy feathers fly in the wind, and accurately observing the distance to which they were carried in any number of half seconds. This method he preferred to that of Dr. Hooke's *mola alata*, or *pneumatica*. (See Phil. Transf. N^o 24. and Birch's Hist. Roy. Soc. vol. iv. p. 225.) He tells us, that he thus measured the velocity of the wind in the great storm of August, 1705, and by many experiments found, that it moved at the rate of thirty-three feet *per* half-second, or of forty-five miles *per* hour: whence he concludes, that the most vehement wind (as that of November, 1703) does not fly at the rate of above fifty or sixty miles *per* hour, and that at a medium the velocity of wind is at the rate of twelve or fifteen miles *per* hour. Phil. Transf. N^o 313. or Abr. vol. iv. p. 411.

Mr. Brice observes, that experiments with feathers are subject to uncertainty: as they seldom or ever describe a straight line, but describe a sort of spirals, moving to the right and left, and rising to very different altitudes in their progress. He, therefore, considers the motion of a cloud, or its shadow, over the surface of the earth, as a much more accurate measure of the velocity of the wind. In this way he found, that the wind, in a considerable storm, moved at the rate of 62.9 miles *per* hour; and that, when it blew a fresh gale, it moved in the same time about twenty-one miles; and that in a small breeze, the wind moved at the rate of 9.9 miles *per* hour. Phil. Transf. vol. lvi. p. 226.

But it has been observed by Cavallo and others, that this method is very fallacious, partly because it is not known whether the clouds do or do not move exactly with the air in which they float; and partly because the velocity of the air in the region where the clouds float is by no means the

same with that of the air which is nearer to the surface of the earth, and is sometimes quite contrary to it, as indicated by the motion of the clouds themselves. Others have estimated the velocity of the wind by the changes effected by it upon the motion of sound, which must of course be very inaccurate. A very simple method of determining the velocity of the wind is that which M. Coulomb (Mem. de l'Acad. Roy. 1781, p. 70.) employed in his experiments on wind-mills, because it requires neither the aid of instruments nor the trouble of calculation. Two persons were placed on a small elevation, at the distance of 150 feet from one another, in the direction of the wind; and, while the one observed, the other measured the time which a small and light feather employed in removing through this space. The distance between the two persons, divided by the number of seconds, gave the velocity of the wind *per* second. The best method, says Cavallo, of measuring the velocity of the wind, is by observing the velocity of the smoke of a low chimney, or by estimating the effect it produces upon certain bodies, and thus may be determined its force as well as its velocity. We shall here observe, that from the concurrence of experiments made with various instruments, and different modes of calculation, it has been inferred, that in currents of air, of the denomination which are expressed in the 4th column of the annexed table, the air moves at the rate of so many feet *per* second as are expressed in the 2d column, or of so many miles *per* hour as are expressed in the 1st column.

A TABLE of the different velocities and forces of the winds, constructed by Mr. Rouse with great care, from a considerable number of facts and experiments, and communicated to Mr. Smeaton, and first published by him in the 51st volume of the Philosophical Transactions.

Velocity of the Wind.		Perpendicular Force on one square Foot, in Avoirdupois Pounds.	Common Appellations of the Forces of Winds.
Miles in one Hour.	= Feet in one Second.		
1	1.47	.005	Hardly perceptible.
2	2.93	.020	
3	4.40	.044	Just perceptible.
4	5.87	.079	
5	7.33	.123	Gentle pleasant wind.
10	14.67	.492	
15	22.00	1.107	Pleasant brisk gale.
20	29.34	1.968	
25	36.67	3.075	Very brisk.
30	44.01	4.429	
35	51.34	6.027	High wind.
40	58.68	7.873	
45	66.01	9.963	Very high.
50	75.35	12.300	
60	88.02	17.715	A storm or tempest.
80	117.36	31.490	A great storm.
			A hurricane.
100	146.70	49.200	{ A hurricane that tears up trees, and carries buildings, &c. before it.

The force of the wind is as the square of its velocity; as Mr. Ferguson has shewn by experiments on the whirling-table; and in moderate velocities this will hold very nearly. Upon

WIND.

Upon this principle the numbers in the third column are calculated. The proposition upon which this column has been formed seems to be, that the impulse of a current of air, striking perpendicularly upon a given surface, with a certain velocity, is equal to the weight of a column of air which has that surface for its base, and for its height the space through which a body must fall, in order to acquire that velocity of the air.

It is observed, with regard to this table, that the evidence for those numbers, where the velocity of the wind exceeds fifty miles an hour, does not seem of equal authority with that of those of fifty miles, or under. Phil. Trans. vol. li. p. 165.

Dr. Hales found (Statical Ess. vol. ii. p. 326.) that the air rushed out of a pair of smith's bellows, at the rate of 68.73 feet in a second of time, when compressed with a force equal to the weight of one inch perpendicular depth of mercury, lying on the whole upper surface of the bellows. The velocity of the air, as it passed out of the trunk of his ventilators, was found to be at the rate of three thousand feet in a minute; which is at the rate of thirty-four miles in an hour. Dr. Hales says, that the velocity with which impelled air passes out at any orifice may be determined by hanging a light valve over the nose of a bellows, by pliant leathern hinges, which will be much agitated and lifted up from a perpendicular to a more than horizontal position by the force of the rushing air. There is another more accurate way, he says, of estimating the velocity of air, viz. by holding the orifice of an inverted glass siphon full of water, opposite to the stream of air, by which the water will be depressed in one leg, and raised in the other, in proportion to the force with which the water is impelled by the air. Descript. of Ventilators, 1743, p. 12, &c.

The velocity and force of the wind are determined experimentally by a peculiar machine, called an *anemometer* or *wind-measurer*. Of these there have been many, variously constructed. See ANEMOMETER, ANEMOSCOPE, and WIND-GAGE.

WIND, *Qualities and Effects of*. 1. "A wind blowing from the sea is always moist; in summer, it is cold; and in winter, warm, unless the sea be frozen up." This is demonstrated thus: there is a vapour continually rising out of all water, (as appears even hence, that a quantity of water, being left a little while in an open vessel, is found sensibly diminished,) but especially if it be exposed to the sun's rays; in which case, the evaporation is beyond all expectation. By this means, the air incumbent on the sea becomes impregnated with a quantity of vapour. But the winds, blowing from off the sea, sweep these vapours along with them; and consequently they are always moist.

Again, water in summer, &c. conceives less heat than terrestrial bodies, exposed to the same rays of the sun, do; but in winter, sea-water is warmer than the earth covered with frost and snow, &c. Wherefore, as the air contiguous to any body is found to partake of its heat and cold, the air contiguous to sea-water will be warmer in winter, and colder in summer, than that contiguous to the earth. Or thus: vapours raised from water by the sun's warmth in winter, are warmer than the air they rise in, (as appears from the vapours condensing, and becoming visible, almost as soon as they are got out into air.) Fresh quantities of vapour, therefore, continually warming the atmosphere over the sea, will raise its heat beyond that of air over the land. Again, the sun's rays reflected from the earth into the air, in summer, are much more than those from the water into air: the air, therefore, over the earth, warmed by the re-

fection of more rays than that over water, is warmer. Hence, *sea-winds* make thick, cloudy, hazy weather.

2. "Winds, blowing from the continent, are always dry; in summer, warm; and cold in winter." For there is much less vapour arising from the earth, than from water; and, therefore, the air over the continent will be impregnated with much fewer vapours. Add, that the vapours, or exhalations, raised by a great degree of heat out of the earth, are much finer, and less sensible, than those from water. The wind, therefore, blowing over the continent, carries but little vapour with it, and is therefore dry.

Farther, the earth in summer is warmer than water exposed to the same rays of the sun. Hence, as the air partakes of the heat of contiguous bodies, that over the earth in summer will be warmer than that over the water: therefore, the winds, &c.

After the like manner it is shewn, that the land-winds are cold in winter. Hence, we see why land-winds make clear cold weather.

Our northerly and southerly winds, however, which are commonly esteemed the causes of cold and warm weather, Dr. Derham observes, are really rather the effect of the cold or warmth of the atmosphere. Hence it is, that we frequently see a warm southerly wind, on a sudden, changed to the north, by the fall of snow or hail; and that in a cold frosty morning, we see the wind north, which afterwards wheels about toward the southerly quarter, when the sun has well warmed the air; and again, in the cold evening, turns northerly, or easterly. See Darwin's Observations *supra*.

For the manner in which north-easterly winds contribute to blights, see BLIGHT. For the effect of winds on the barometer and thermometer, see BAROMETER, &c.

The utility of winds has been universally acknowledged. The ancient Persians, Phœnicians, Greeks, and Romans, sacrificed and erected temples to the winds; as we learn from Vossius, Theolog. Gentil. lib. iii. part i. cap. i. Besides their use in moving bellows, mills, and other machines, applied in various ways to the service of mankind, and the benefits resulting from them to navigation and trade, they serve to purify and refresh the air, to convey the heat or cold of one region to another, to produce a regular circulation of vapours from the ocean to countries remote from it, and to supply, by wafting them in their progress against hills, &c. springs and rivers.

Wind has been, by many authors, made the basis of many different diseases: among others, Dr. Reyn has given it as his opinion, in a Treatise on the Gout (De Arthritid.), that flatules, or wind inclosed between the periosteum and the bone, are the true cause of that disease; and accordingly, that all the methods of cure ought to tend to the expelling of that wind.

He is also of opinion, that head-aches, palpitations of the heart, tooth-ache, pleurisy, convulsions, colics, and many other diseases, are originally owing to the same cause, and only differ in regard to the place affected, and to the various motions and determinations of the wind. The moveableness of the pain in gouty persons from one part to another, he looks on as a proof of this, and thinks that the curing of the gout by burning moxa, or the cotton of the mugwort leaves, upon it, is owing to its giving way to the wind in the part to evaporate itself.

That these winds are cold, appears from the shivering fits which generally precede a paroxysm of the gout; and that the shiverings in the beginning of fevers, and before all fits of agues, are owing to the same cause, is supposed by
this

this author a natural conclusion from the former observations.

Their differences, he says, principally proceed from the various ferments producing in us a variety of humours; which acting upon one another, do in their effervescences create winds of various effects, and denominate diseases from the places which are the scenes of their action. It is on this account that the *acupunctura*, or pricking with long needles, among the Chinese, is of use: the Japanese, and other neighbouring nations, having no other cure for most diseases than the pricking with the needle, and the burning of the moxa on the part.

The husbandman often suffers extremely by high winds in many different respects. Plantations of trees, at a small distance from the barns and houses, are the best safeguard against their suffering by winds; but they must not be planted so near as that their fall, if it should happen, would endanger them. Yews grow very slowly, otherwise they are the best of all trees for this defensive plantation. Trees suffer by winds, being either broken or blown down by them: but this may be in a great measure prevented by cutting off great part of the heads and branches of them, in places where they stand most exposed.

Hops are the most subject to be injured by winds of any crop; but this may be in a great measure prevented by a high pale, or very thick thorn-hedge; this will both keep off the spring wind, which nips the young buds, and be a great safeguard against other winds that would tear the plants from their poles. The poles should always be very firm in the ground; and the best security to be added to this, is a row of tall trees all round the ground.

Winds, attended with rain, do great injury to the corn, by laying it flat to the ground. The best method of preventing this, is to keep up good enclosures; and if the accident happens, the corn should be cut immediately, for it never grows at all afterwards. It should be left on the ground, in this case, some time after the cutting, to harden the grain in the ear. Mortimer's Husbandry, p. 302.

WIND, in *Navigation*, is the same agitation of the air, considered as serving for the motion of vessels on the water.

If the wind blows gently, it is called a *breeze*; if it blows harder, it is called a *gale*, or a stiff gale; and if it blows very hard, it is called a *storm*.

The following observations on the wind have been made by skilful seamen, and particularly by Dr. Halley.

1. Between the limits of 60° , *viz.* from 30° of north latitude to 30° of south latitude, there is a constant, or almost constant, east wind through the year, blowing in the Atlantic and Pacific oceans, called the *trade-wind*; which see.

2. The trade-winds, near their northern limits, blow between the north and east; and near their southern limits they blow between the south and east.

The trade-wind seems to depend principally upon the rarefaction of the air, which is occasioned by the heat of the sun progressively from the east towards the west. The air which is rarefied, and, of course, elevated by the heat of the sun immediately over it, is condensed, and descends as soon as the sun is gone over another place to the west of the former; then the air of the latter place is rarefied, and the condensed air of the former rushes towards it, &c. From the northern and southern parts of the world, the air likewise runs to the place which is immediately under the sun; but those directions, combining with the easterly wind, which blows nearer to the equator, form the above-mentioned

north-easterly and south-easterly winds on the borders of the trade-wind.

3. These general motions of the wind are disturbed on the continents, and near their coasts.

In places that are farther from the equator, the rarefaction which arises from the heat of the sun, and from the attraction of the sun and moon, is less active; and is besides influenced by a variety of local and accidental circumstances, such as extensive continents, mountains, rains, islands, &c. which disturb, interrupt, or totally change the direction of the wind. Hence, in those latitudes north and south, which are beyond the limits of the trade-wind, or near the coasts, the winds are very uncertain; nor has any good theory been as yet formed respecting them.

4. In some parts of the Indian ocean there are periodical winds, which are called *Monsoons*; which see.

For the explication of these, it is said, that as the air, which is cool and dense, will force the warm rarefied air in a continual stream upwards, there it must spread itself to preserve the equilibrium. Therefore the upper course or current of air must be contrary to the under current; for the upper air must move from those parts where the greatest heat is; and so, by a kind of circulation, the N.E. trade-wind below will be attended with a S.W. above; and a S.E. below, with a N.W. above.

5. In the Atlantic ocean, near the coasts of Africa, at about a hundred leagues from the shore, between the latitudes of 28° and 10° north, seamen constantly meet with a fresh gale of wind blowing from the N.E.

6. Those bound to the Caribbee islands, across the Atlantic ocean, find, as they approach the American side, that the said N.E. wind becomes easterly; or seldom blows more than a point from the east, either to the northward or southward. These trade-winds, on the American side, are extended to 30° , 31° , or even to 32° of N. latitude; which is about 4° farther than they extend on the African side: also to the southward of the equator, the trade-winds extend three or four degrees farther toward the coast of Brasil, on the American side, than they do near the Cape of Good Hope, on the African side.

7. Between the latitudes of 4° N. and 4° S., the wind always blows between the south and east: on the African side, the winds are nearest the south; and on the American side, nearest the east. In these seas, Dr. Halley observed, that when the wind was eastward, the weather was gloomy, dark, and rainy, with hard gales of wind; but when the wind veered to the southward, the weather generally became serene, with gentle breezes, approaching to a calm. These winds are somewhat changed by the seasons of the year; for when the sun is far northward, the Brasil S.E. wind turns to the south, and the N.E. wind to the east; and when the sun is far south, the S.E. wind gets to the east, and the N.E. winds on this side of the equator veer more to the north.

8. Along the coast of Guinea, from Sierra Leone to the island of St. Thomas, under the equator, which is above five hundred leagues, the southerly and south-west winds blow perpetually; for the S.E. trade-wind, having passed the equator, and approaching the Guinea coast within eighty or a hundred leagues, inclines toward the shore, and becomes south, then S.E., and by degrees, as it comes near the land, it veers about to south, S.S.W., and in with the land it is S.W. and sometimes W.S.W. This tract is subject to frequent calms, violent sudden gusts of winds, called tornadoes, blowing from all points of the horizon.

The westerly wind on the coast of Guinea is probably owing

owing to the nature and situation of the land, which, being greatly heated by the sun, rarefies the air exceedingly; hence the cooler and heavier air from over the sea will keep rushing in to restore the equilibrium.

9. Between the fourth and tenth degrees of north latitude, and between the longitudes of Cape Verd, and the easternmost of the Cape Verd isles, there is a tract of sea subject to perpetual calms, attended with frequent thunder and lightning, and rains; whence this part of the sea is called 'The Rains.' Ships in sailing these six degrees are said to have been sometimes detained whole months.

The cause of this seems to be, that the westerly winds setting in on this coast, and meeting the general easterly wind in this tract, balance each other, and cause the calms; and the vapour carried thither by the hottest wind, meeting the coolest, is condensed, and occasions the very frequent rains.

The three last observations account for two circumstances which mariners experience in sailing from Europe to India, and in the Guinea trade.

The *first* is the difficulty which ships, in going to the southward, especially in the months of July and August, find in passing between the coast of Guinea and Brasil, although the breadth of this sea is more than five hundred leagues. This happens, because the S.E. winds at that time of the year commonly extend some degrees beyond the ordinary limits of four degrees north latitude; and besides coming so much southerly, as to be sometimes south, sometimes a point or two to the west; it then only remains to ply to windward: and if, on the one side, they steer W.S.W. they get a wind more and more easterly; but then there is a danger of falling in with the Brasilian coast, or shoals; and if they steer E.S.E. they fall into the neighbourhood of the coast of Guinea, from whence they cannot depart without running easterly as far as the island of St. Thomas; and this is the constant practice of all the Guinea ships.

Secondly, With regard to all ships departing from Guinea for Europe, their direct course is northward; but on this course they cannot go, because the coast bending nearly east and west the land is to the northward: therefore, as the winds on this coast are generally between the S. and W.S.W., they are obliged to steer S.S.E. or S., and with these courses they run off the shore; but in so doing they always find the winds more and more contrary; so that when near the shore they can lie south, at a greater distance they can make no better than S.E., and afterwards E.S.E.; with which courses they commonly fetch the island of St. Thomas and Cape Lopez, where, finding the winds to the eastward of the south, they sail westerly with it, till coming to the latitude of four degrees south, they there find the S.E. winds blowing perpetually.

On account of these general winds, all those that use the West India trade, even those bound to Virginia, reckon it their best course to get as soon as they can to the southward, that so they may be certain of a fair and fresh gale to run before it to the westward; and for the same reason, those homeward-bound from America endeavour to gain the latitude of thirty degrees, where they first find the winds begin to be variable; though the most ordinary winds in the North Atlantic ocean come from between the south and west.

10. Between the southern latitudes of ten and thirty degrees in the Indian ocean, the general trade-wind about the S.E. by S. is found to blow all the year long in the same manner as in the like latitude in the Ethiopic ocean; and during the six months from May to December, these winds reach to within two degrees of the equator; but

during the other six months, from November to June, a N.W. wind blows in the tract lying between the third and tenth degrees of southern latitude, in the meridian of the north end of Madagascar; and between the second and twelfth degree of south latitude, near the longitude of Sumatra and Java.

11. In the tract between Sumatra and the African coast, and from three degrees of south latitude quite northward to the Asiatic coasts, including the Arabian sea and the gulf of Bengal, the monsoons blow from September to April on the N.E., and from March to October on the S.W. In the former half year the wind is more steady and gentle, and the weather clearer than in the latter six months; and the wind is more strong and steady in the Arabian sea than in the gulf of Bengal.

12. Between the island of Madagascar and the coast of Africa, and thence northward as far as the equator, there is a tract, in which, from April to October, there is a constant fresh S.S.W. wind; which to the northward changes into the W.S.W. wind, blowing at that time in the Arabian sea.

13. To the eastward of Sumatra and Malacca on the north of the equator, and along the coasts of Cambodia and China, quite through the Philippines as far as Japan, the monsoons blow northerly and southerly; the northern setting in about October or November, and the southern about May: these winds are not quite so certain as those in the Arabian seas.

14. Between Sumatra and Java to the west, and New Guinea to the east, the same northerly and southerly winds are observed; but the first half-year monsoon inclines to the N.W., and the latter to the S.E. These winds begin a month or six weeks after those in the Chinese seas set in, and are quite as variable.

15. These contrary winds do not shift from one point to its opposite all at once: in some places, the time of the change is attended with calms; in others, by variable winds; and it often happens on the shores of Coromandel and China, towards the end of the monsoons, that there are most violent storms, greatly resembling the hurricanes in the West Indies; in which the wind is so very strong, that hardly any thing can resist its force.

All navigation in the Indian ocean must necessarily be regulated by these winds; for if mariners should delay their voyages till the contrary monsoon begins, they must either sail back, or go into harbour, and wait for the return of the trade-wind.

16. The irregularities of the wind in countries which are farther from the equator than those which have been mentioned above, or nearer to the poles of the earth, are so great that no particular period has as yet been discovered, excepting that in particular places certain winds are more likely to blow than others. Thus at Liverpool the winds are said to be westerly for near two-thirds of the year; in the southern part of Italy, a south-east wind (called the *schirocco*) blows more frequently than any other wind, &c.

17. The temperature of a country with respect to heat or cold is increased or diminished by winds, according as they come from a hotter or colder part of the world. The north and north-easterly winds, in this country and all the western parts of Europe, are reckoned cold and drying winds. They are cold, because they come from the frozen region of the north pole, or over a great tract of cold land. Their drying quality is derived from their coming principally over land, and from a well-known property of the air; namely, that warm air can dissolve, and keep dissolved, a

greater quantity of water than colder air: hence the air which comes from colder regions, being heated over warmer countries, becomes a better solvent of moisture, and dries up with greater energy the moist bodies it comes in contact with; and, on the other hand, warm air coming into a colder region deposits a quantity of the water it kept in solution, and occasions mists, fogs, clouds, rains, &c. "In short," says colonel Roy, "the winds seem to be drier, denser, and colder, in proportion to the extent of land they pass over from the poles towards the equator; but they appear to be more moist, warm, and light, in proportion to the extent of ocean they pass over from the equator towards the poles. Hence the humidity, warmth, and lightness, of the Atlantic winds to the inhabitants of Europe. On the east coasts of North America the severity of the N.W. wind is universally remarked; and there can scarcely be a doubt, that the inhabitants of California, and other parts on the west side of that great continent, will, like those on the west of Europe, feel the strong effects of a N.E. wind."

18. In warm countries, sometimes the winds, which blow over a great tract of highly-heated land, become so very drying, scorching, and suffocating, as to produce dreadful effects. These winds, under the names of *Blooms*, *Samiel*, and *Solanos*, are often felt in the deserts of Arabia, in the neighbourhood of the Persian gulf, in the interior of Africa, and in some other places. There are likewise in India, part of China, part of Africa, and elsewhere, other winds, which deposit so much warm moisture as to soften, and actually to dissolve glue, salts, and almost every article which is soluble in water.

19. It is impossible to give any adequate account of irregular winds, especially of those sudden and violent gusts as come on at very irregular periods, and generally continue for a short time. They sometimes spread over an extensive tract of country, and at other times are confined within a remarkably narrow space. Their causes are by no means rightly understood, though they have been vaguely attributed to peculiar rarefactions, to the combined attractions of the sun and moon, to earthquakes, to electricity, &c. They are called in general *hurricanes*, or they are the principal phenomenon of a hurricane, that is, of a violent storm.

Almost every one of those violent winds is attended with particular phenomena, such as droughts, or heavy rains, or hail, or snow, or thunder and lightning, or several of those phenomena at once. They frequently shift suddenly from one quarter of the horizon to another, and then come again to the former point. In this case they are called *tornadoes*.

In mountainous countries, the wind sometimes rages with extreme violence, and the mountains generally exhibit signs of the approaching storm. Thus, at the Cape of Good Hope, there are four remarkable mountains, called *Table Land*, or *Mountain*; *Sugar-Loaf*, or the *Lion's Head*; *James Mount*, or the *Lion's Rump*; and *Charles Mount*, called also the *Devil's Tower*, or *Devil's Head*, from the violent squalls of wind which come from it. In the summer season *Table Mountain* is sometimes suddenly covered with a white cloud, called the *Table-cloth*; when this cloud seems to roll down the steep face of the mountain, it is a sure indication of an approaching gale of wind from the S.E., which generally blows with great violence, and sometimes continues a day or more, but in common is of short duration. On the first appearance of this cloud, the ships in *Table bay* begin to prepare for it, by striking yards and top-masts, and making every thing as snug as possible. If, in the morning, the cloud extends from the *Table* to *Mount Charles*, or the *Devil's Tower*, which are almost contiguous,

it is a general saying among seamen, that the old gentleman is going to breakfast; if in the middle of the day, that he is going to dinner; and if in the evening, that the cloth is spread for supper.

There are various other periodical winds: of these, however, that generally known by the name of *Limat*, which is common in the island of Cyprus, shall only be mentioned here. The period of this wind is five days: on the first day, it begins to blow at eight in the morning, and increases till noon; from thence it gradually weakens, and ceases entirely about three P.M. On the second day, it arises at the same hour; but it does not attain its greatest strength till about one in the afternoon, and ceases at four. On the third day, it begins as before; but it falls an hour later. On the remaining days, it follows the same progression as on the third; but it is remarked, that a little before it ceases, it becomes extremely violent. Upon the N.W. side of the above island, this wind is considered as a sea-breeze; and upon the S.E. as a land-breeze. See *WIND, Qualities of, supra*. See also *HURRICANES, TORNADOES, and WHIRL-Wind*. See *Phil. Trans. N° 183, or Abr. vol. ii. p. 133, &c.* Robertson's *Elem. of Nav. b. vi. f. 6.* Cavallo's *Philos. vol. ii.*

The winds are divided, with respect to the points of the horizon from which they blow, into *cardinal* and *collateral*.

WINDS, Cardinal, are those blowing from the four cardinal points; east, west, north, and south.

Thus, a wind that blows from the E. towards the W. is called *east wind*; when it blows from the W. towards the E., *west wind*; when it blows from the N. to the S., it is called *north wind*; and when it blows from the S. towards the N., it is called *south wind*.

WINDS, Collateral, are the intermediate winds between any two cardinal winds. The number of these is infinite, as the points from which they blow are; but only a few of them are considered in practice; *i. e.* only a few of them have their distinguishing names.

Those winds which deviate a little from the cardinal points are called *northerly, easterly, southerly, and westerly* winds. But for the sake of greater distinction, the space or arch which lies between any two contiguous cardinal points, is supposed, by the mariners, to be divided into eight equal parts, or *points*, and each point into four equal parts, called *quarter-points*. So that the horizon is supposed to be divided into thirty-two principal points, which are called *rhumbs*, or *winds*, to each of which a particular name is assigned; and those names are derived from the names of the adjacent cardinal points. See *COMPASS*.

The ancient Greeks, at first, only used the four cardinal ones; at length they took in four more. Vitruvius gives us a table of twenty, besides the cardinals, which were in use among the Romans.

The moderns, as their navigation is much more perfect than that of the ancients, have given names to twenty-eight collateral winds, which they range into *primary* and *secondary*; and the secondary they subdivide into those of the *first* and *second order*.

The English names of the primary collateral winds and points are compounded of the names of the cardinal ones, north and south being still prefixed.

The names of the secondary collateral winds of the first order are compounded of the names of the cardinals, and the adjacent primary one. Those of the second order are compounded of the names of the cardinal, or the next adjacent primary; and the next cardinal, with the addition of the word *by*. The Latins have distinct names for each; all which are expressed in the following Table.

WIND.

Names of the Winds and Points of the Compass.		Distances of the Points, &c. from the North.
English.	Latin and Greek.	
1. North.	<i>Septentrio, or Boreas.</i>	0° 0'
2. North by east.	{ <i>Hyperboreas.</i> <i>Hypaquilo.</i> <i>Gallicus.</i> }	11 15
3. North-north-east.	<i>Aquilo.</i>	22 30
4. North-east by north.	{ <i>Mefoboreas.</i> <i>Mefaquilo.</i> <i>Supernas.</i> }	33 45
5. North-east.	{ <i>Aræapeliotes.</i> <i>Borapeliotes.</i> <i>Græcus.</i> }	45
6. North-east by east.	<i>Hypocæfias.</i>	56 15
7. East-north-east.	<i>Cæfias, Hellefpontius.</i>	67 30
8. East by north.	{ <i>Mefocæfias.</i> <i>Carbas.</i> }	78 45
		From the E.
9. East.	{ <i>Solanus, subfolanus,</i> <i>apeliotes.</i> }	0° 0'
10. East by south.	{ <i>Hypeurus, or hy-</i> <i>pereurus.</i> }	11 15
11. East-south-east.	<i>Eurus, or voltarnus.</i>	22 30
12. South-east by east.	<i>Mefeurus.</i>	33 45
13. South-east.	<i>Notapeliotes, curaster.</i>	45
14. South-east by south.	<i>Hypophænix.</i>	56 15
15. South-south-east.	{ <i>Phænix, phœnicias,</i> <i>leuco-notus, gan-</i> <i>geticus.</i> }	67 30
16. South by east.	<i>Mefophænix.</i>	78 45
		From the S.
17. South.	<i>Aufter, notus, meridiæ.</i>	0° 0'
18. South by west.	{ <i>Hypolibonotus, al-</i> <i>fanus.</i> }	11 15
19. South-south-west.	{ <i>Libonotus, notoliby-</i> <i>cus, auftro-africus.</i> }	22 30
20. South-west by south.	<i>Mefolibonotus.</i>	33 45
21. South-west.	{ <i>Noto-zephyrus.</i> <i>Noto-libycus.</i> <i>Africus.</i> }	45
22. South-west by west.	{ <i>Hypolibs.</i> <i>Hypafricus.</i> <i>Subvefperus.</i> }	56 15
23. West-south-west.	<i>Libs.</i>	67 30
24. West by south.	{ <i>Mefolibs.</i> <i>Mefozephyrus.</i> }	78 45

Names of the Winds and Points of the Compass.		Distances of the Points, &c. from the West.
English.	Latin and Greek.	
25. West.	{ <i>Zephyrus, favonius,</i> <i>occidens.</i> }	0° 0'
26. West by north.	{ <i>Hypargeftes.</i> <i>Hypocorus.</i> }	11 15
27. West-north-west.	{ <i>Argeftes.</i> <i>Caurus, corus,</i> <i>iapyx.</i> }	22 30
28. North-west by west.	{ <i>Mefargeftes.</i> <i>Mefocorus.</i> }	33 45
29. North-west.	{ <i>Zephyro-boreas, boro-</i> <i>libycus, olympias.</i> }	45
30. North-west by north.	{ <i>Hypocircius.</i> <i>Hypothrafcias.</i> <i>Scirem.</i> }	56 15
31. North-north-west.	<i>Circius, thrafcias.</i>	67 30
32. North by west.	<i>Mefocircius.</i>	78 45

Note.—The ancient names are here, after Ricciolus, adapted to the modern ones; not that the winds formerly denoted by those were precisely the same with these, (for the ancient number and division being different from the modern, the points they refer to will necessarily be somewhat different,) but these are what come the nearest. Thus, Vitruvius, only reckoning twenty-four winds, difposes the points they refer to in a different order; as in the following Table.

Names of the Winds.	Distance from North.	Names of the Winds.	Distance from East.
1. <i>Septentrio.</i>	0°	7. <i>Solanus.</i>	0°
2. <i>Gallicus.</i>	15	8. <i>Ornithias.</i>	15
3. <i>Supernas.</i>	30	9. <i>Cæfias.</i>	30
4. <i>Aquilo.</i>	45	10. <i>Eurus.</i>	45
5. <i>Boreas.</i>	60	11. <i>Voltarnus.</i>	60
6. <i>Carbas.</i>	75	12. <i>Euronotus.</i>	75
Names of the Winds.	Distance from South.	Names of the Winds.	Distance from West.
13. <i>Aufter.</i>	0°	19. <i>Favonius.</i>	0°
14. <i>Alfanus.</i>	15	20. <i>Etefæ.</i>	15
15. <i>Libonotus.</i>	30	21. <i>Circius.</i>	30
16. <i>Africus.</i>	45	22. <i>Caurus.</i>	45
17. <i>Subvefper.</i>	60	23. <i>Corus.</i>	60
18. <i>Argeftes.</i>	75	24. <i>Thrafcias.</i>	75

WIND.

The following Table shews the angles which every rhumb or point of the compass makes with the meridian: by means of which the direction of the wind, &c. may be determined.

NORTH.	SOUTH.	Points.	D.	M.	NORTH.	SOUTH.
		$\frac{1}{4}$	2	49		
		$\frac{1}{2}$	5	$37\frac{1}{2}$		
		$\frac{3}{4}$	8	26		
N. by E.	S. by E.	1	11	15	N. by W.	S. by W.
		$1\frac{1}{4}$	14	4		
		$1\frac{1}{2}$	16	$52\frac{1}{2}$		
		$1\frac{3}{4}$	19	41		
N.N.E.	S.S.E.	2	22	30	N.N.W.	S.S.W.
		$2\frac{1}{4}$	25	19		
		$2\frac{1}{2}$	28	$7\frac{1}{2}$		
		$2\frac{3}{4}$	30	56		
N.E. by N.	S.E. by S.	3	33	45	N.W. by N.	S.W. by S.
		$3\frac{1}{4}$	36	34		
		$3\frac{1}{2}$	39	$22\frac{1}{2}$		
		$3\frac{3}{4}$	42	11		
N.E.	S.E.	4	45	0	N.W.	S.W.
		$4\frac{1}{4}$	47	49

For the use of the winds in navigation, &c. see SAILING.
WIND, a disease in sheep of a very dangerous and distressing kind.

It is observed in the Shepherd's Guide, that in this complaint, the sheep, immediately after being clipped or shorn, appear to be in violent pain, their sides are somewhat extended, and their breathing very short, the head is hung down drooping, and they have a great aversion to moving or walking. These symptoms continue to increase until the sheep dies, which is in a very few hours, unless a violent purging comes on, which generally gives immediate relief. On inquiring for the name of this affection, the writer says, he found it was called the wind, but where the seat of it lay few could tell him; some thought it was in the head, others in the lungs; and the remedies they applied were as various as their opinions of the nature of the disease.

Not being satisfied with these accounts, he endeavoured, by inspecting the carcases of sheep that died of the disease, to discover the cause and seat of the complaint. On opening four sheep that died of the disease, he found all

the intestines rather distended with flatus, but not in any great degree. Their blood-vessels were very turgid, and of a deep red, particularly those of the large intestines, excepting the rectum, or what is called the *bum-gut*, which had a healthy appearance, as likewise had the stomach, milt, caul, liver, heart, lungs, and in short all the viscera contained in the cavity of the trunk. From these appearances he will venture to say, that the disease in question is a violent inflammation of the intestines, perhaps in some measure arising from bruises in shearing, but more so from losing a warm clothing, and being suddenly exposed to cold air and cold feeding.

He therefore recommends to farmers, that on the first appearances of the complaint they put the sheep into a stable or other warm place, and immediately bleed it freely. Then to bruise a quarter of an ounce of some carminative seed, such as carraway, anise, cummin, or fennel, and to mix these with two ounces of Glauber's purging salts, in a pint of water, placing it on a fire, and making it boil for a few minutes, then to strain it off. Then to add a quarter of an ounce

ounce of powdered jalap, and while lukewarm to give the sheep a quarter of a pint of this liquor, well shaken together, every half hour till it dungs. It should have no food or cold water until recovered, but a little warm water might be of service in some cases.

This is a disorder which is in general so suddenly fatal, that recourse should be instantly had to any remedy that may have been found beneficial; but bleeding is probably that on which the greatest dependence may be placed, with calomel in some instances.

WIND, among *Animals*, is another name for the breath, or rather for the power with which the lungs are endowed in the exercise of their functions, which in many cases is a sort of morbid affection of them, especially in horses, swine, calves, and some others. Horses are often thick-winded and purfise, which is this state, and require much exercise and management, and the other two are sometimes affected in much the same way.

WIND, in *Rural Economy*, a term applied to a winch or wince in some places.

WIND, *Fresh*. See FRESH.

WIND, *To haul the*. See HAUL.

WIND, *Large*, in the *Sea Language*. See LARGE.

WIND, *Quarter*, at *Sea*. See QUARTER.

WINDS, *Reigning*. See REIGNING.

WINDS, *Tropic*. See TRADE-WINDS, and WIND *supra*.

WIND, *Side*, at *Sea*, that which blows on the side of the ship.

To WIND a Ship or Boat, in *Sea Language*, is to change her position, by bringing the stern to lie in the situation of the head, or directly opposite to its former situation.

WIND, in the *Manege*. A horse that carries in the wind, is one that tosses his nose as high as his ears, and does not carry handsomely.

The difference between carrying in the wind and beating upon the hand is, that a horse who beats upon the hand shakes his head, and resists the bridle; but he who carries in the wind, puts up his head without shaking, and only sometimes beats upon the hand. The opposite to carrying in the wind is arming and carrying low.

WIND, *Whirl*. See WHIRL-WIND.

WIND, *Colic*. See COLIC.

WIND-*Dropsy*. See TYMPANITES.

WIND-*Egg*, an addle egg, or an egg that has taken wind. See EGG.

WIND-*Fall* denotes fruit blown off the tree by the wind.

WIND-*Flower*, in *Botany*. See ANEMONE.

WIND-*Furnace*. See FURNACE.

WIND-*Gage*, in *Pneumatics*, an instrument serving to determine the velocity and force of the wind. See ANEMOMETER, ANEMOSCOPE, and *Laws of the Force, &c. of the Wind supra*.

Dr. Lind, of Edinburgh, has contrived an apparatus of this kind, which is simple and easy of construction, and which seems to be well adapted for measuring the force of the wind with a sufficient degree of accuracy. This instrument consists of two glass tubes A B, C D, (*Plate XV. Pneumatics, fig. 9.*) five or six inches in length, and about four-tenths of an inch in bore; which are connected together like a siphon, by a small bent glass tube *a b*, the bore of which is one-tenth of an inch in diameter. On the upper end of the leg A B there is a tube of latten brass, which is kneed or bent perpendicularly outwards, and has its mouth open towards F; on the other leg C D is a cover, with a round hole G in the upper part of it, two-tenths of an inch in diameter. This cover and the kneed tube are connected

together by a slip of brass, *c d*, which strengthens the whole instrument, and serves to hold the scale H I. The kneed tube and cover are fixed on with hard cement, or sealing-wax. To the same tube is soldered a piece of brass, *e*, with a round hole in it, to receive the steel spindle K L, and at *f* another such piece of brass is soldered to the brass hoop *g h*, which surrounds both legs of the instrument. There is a small shoulder on the spindle at *f*, upon which the instrument rests, and a small nut *i*, to prevent it from being blown off the spindle by the wind. The whole instrument is easily turned round upon the spindle by the wind, so as always to present the mouth of the kneed tube toward it. At the end of the spindle there is a screw, by which it may be screwed to the top of a post or stand: it has also a hole at L, to admit a small lever for screwing it into wood with greater facility. A thin plate of brass *k* is soldered on the kneed tube, about half an inch above the round hole G, so as to prevent rain from falling into it. There is also a crooked tube A B (*fig. 10.*), to be put occasionally upon the mouth of the kneed tube F, in order to prevent rain from being blown into the mouth of the wind-gage, when it is left exposed to the rain.

This instrument serves to ascertain the force of the wind, by filling the tube half full of water, and pushing the scale a little up or down, till *o* upon the scale, when the instrument is held perpendicularly, be on a line with the surface of the water, in both legs of the wind-gage. The instrument being thus adjusted, hold it up perpendicularly, and turning the mouth of the kneed tube toward the wind, observe how much the water is depressed by it in one leg, and how much it is raised in the other. The sum of the two is the height of a column of water, which the wind is capable of sustaining at that time; and every body that is opposed to that wind, will be pressed upon by a force equal to the weight of a column of water, having its base equal to the surface that is opposed, and its height equal to the altitude of the column of water sustained by the wind in the wind-gage. Hence the force of the wind upon any body, where the surface opposed to it is known, may be easily found; and a ready comparison may be made betwixt the strength of one gale of wind, and that of another, by knowing the heights of the columns of water which the different winds were capable of sustaining. The heights of the column in each leg will be equal, provided that the legs are of equal bores; but unequal if their bores are unequal. For suppose the legs equal, and the column of water sustained by the wind to be three inches, the water in the leg which the wind blows into will be depressed $1\frac{1}{2}$ inch below *o*, and raised as much in the other leg. But if the bore of the leg which the wind blows into be double that of the other, the water in that leg will be depressed only one inch, whilst it is raised twice as much, or two inches, in the other, and *vice versa*.

The force of the wind may likewise be measured with this instrument, by filling it till the water runs out at G. For if it be then held up to the wind as before, a quantity of water will be thrown out; and if both legs of the instrument are of the same bore, the height of the column sustained will be equal to double the column of water in either leg, or the sum of what is wanting in both legs. But if the legs are of unequal bores, neither of these will give the true height of the column of water which the wind sustained. For, obtaining in this case the true height, Dr. Lind has subjoined the requisite formulæ. The use of the small tube of communication *a b* (*fig. 9.*), is to check the undulation of the water, so that the height of it may be read off from the scale with ease and certainty; and also to prevent the

water from being thrown up to a much greater or less altitude than the true height of the column which the wind is able at that time to sustain. The author has calculated a table, by means of which, having the height of the column of water sustained in the wind-gage, the force of the wind upon a foot square may be determined.

Height of the Water in the Gage.	Force of the Wind on One Foot Square in Pounds Avoirdupois.	Common Designations of such Winds.
Inches.		
12	62.500	
11	57.293	
10	52.083	Most violent hurricane.
9	46.875	
8	41.667	Very great hurricane.
7	36.548	Great hurricane.
6	31.750	Hurricane.
5	26.041	Very great storm.
4	20.833	Great storm.
3	15.625	Storm.
2	10.416	Very high wind.
1	5.208	High wind.
0.5	2.604	Brisk gale.
0.1	0.521	Fresh breeze.
0.05	0.260	Pleasant wind.
0.025	0.030	A gentle wind.

When the height of the water is not exactly mentioned in the table, then that height may be separated into such parts as are mentioned in the table, and the sum of the forces answering to such parts will be the force of the wind correspondent to the height in question: thus, if the height of the water be 4.6 inches; then this height is equal to 4 + 0.5 + 0.1, which parts are all in the table; therefore,

Inches.	Pounds.
4	20.833
0.5	2.604
0.1	0.521

The sum is 23.958, which expresses the force of the wind when the height of the water in the gage is 4.6 inches.

Any alteration that can usually take place in the temperature of the water, makes no sensible difference in this instrument.

In frosty weather this gage cannot be used with common water. At that time some other liquor must be used, which is not so subject to freeze; and, upon the whole, a saturated solution of common salt in water is the most eligible: but in that case, (since the specific gravity of a saturated solution of salt is to that of pure water, as 1.244 to 1,) the forces which are stated in the preceding table must be multiplied by 1.244. Thus, if in the preceding example the saturated solution of salt had been used instead of water only, the force of the wind on a square foot would have been 29.8 pounds.

When salt-water is used, the force of the wind, which is stated in the table, must be increased in the proportion of the specific gravity of salt-water to that of common water; thus, using the preceding example, we must say, as 1 : 1.244 : : 23.958 to a fourth proportional, which must be found by

multiplying the second term by the third, and then dividing the product by the first term; but, the first term being unity, we need only multiply 23.958 by 1.244.

On the 9th of May, 1775, Dr. Lind observed, that the wind supported a column of water in his wind-gage 6 $\frac{7}{10}$ inches in height; and from his table it appeared, that the force of the wind in this hurricane, which did great damage to the gardens in his neighbourhood, was equal to 34.921 pounds avoirdupois, on every square foot.

If the velocity and density of the wind in any particular case were accurately determined, this instrument, which gives its force or momentum, would enable us to ascertain the velocity in every other case, the density being known: for the force of the wind is as the square of its velocity. Phil. Trans. vol. lxxv. part ii. art. 34. p. 353, &c.

Mr. Martin, from a hint first suggested by Dr. Burton, contrived an anemoscope, or wind-gage, of the following construction. A B C D E F G H I (fig. 11.) is an open frame of wood, firmly supported by the shaft or postern I. In the two cross pieces H K, L M, is moved an horizontal axis Q M, by means of the four sails *a b, c d, e f, g h*, in a proper manner, exposed to the wind. Upon this axis is fixed a cone of wood M N O, upon which, as the sails move round, a weight S is raised by a string on its superficies, proceeding from the small to the largest end N O. Upon the great end or base of the cone is fixed a ratchet-wheel *i k*, in whose teeth falls the click X, to prevent any retrograde motion from the depending weight.

From the structure of this machine, it is easy to understand, that it may be accommodated to estimate the variable force of the wind, because the force of the weight will continually increase, as the string advances on the conical surface, by acting at a greater distance from the axis. And, therefore, if such a weight be put on, on the smallest part at M, as will just keep the machine in equilibrio with the weakest wind; then as the wind becomes stronger, the weight will be raised in proportion, and the diameter of the base of the cone N O may be so large in comparison of that of the smaller end or axis at M, that the strongest wind shall but just raise the weight to the great end.

Thus, for example, let the diameter of the axis be to that of the base of the cone N O as 1 to 28; then if S be a weight of one pound at M on the axis, it will be equivalent to twenty-eight pounds, or $\frac{1}{4}$ of an hundred, when raised to the greatest end. If, therefore, when the wind is weakest, it supports one pound on the axle, it must be twenty-eight times as strong to raise the weight to the base of the cone. Thus may a line or scale of twenty-eight equal parts be drawn on the side of the cone, and the strength of the wind will be indicated by that number therein from which the string shall at any time hang.

Furthermore, the string may be of such a size, and the cone of such a length, that there shall be sixteen revolutions of the string between each division of the scale on the cone; so will the strength of the wind be expressed in pounds and ounces. And if greater exactness be required, let the periphery of the cone's base be divided into sixteen equal parts; then whenever the equilibrium happens, the string will leave the conic surface against one of those divisions, and thus shew the force of the wind to a drachm avoirdupois weight. Martin's Phil. Brit. vol. ii. p. 211, &c.

M. Bouguer contrived a very simple instrument, by means of which we may immediately discover the force which the wind exerts on a given surface. This is a hollow tube A A B B (fig. 12.), in which a spiral string C D is fixed, that may be more or less compressed by a rod F S D, passing

passing through a hole within the tube at A A ; then having observed to what degree different forces or given weights are capable of compressing the spiral, mark divisions on the rod in such a manner, that the mark at S may indicate the weight requisite to force the spring into the situation C D ; afterwards join at right angles to this rod at F, a plane surface E F E of a given area, either greater or less, at pleasure ; then let this instrument be opposed to the wind, so that it may strike the surface in the directions V E, V E, parallel to that of the rod, and the mark at S will shew the weight to which the force of the wind is equivalent.

The ingenious professor Leslie (Enquiry into the Nature and Propagation of Heat) having found, in the course of his experiments on heat, that the refrigerant, or cooling power of a current of air, is exactly proportional to its velocity, derives from this principle the construction of a new and simple anemometer. "It is in reality nothing more," says he, "than a thermometer, only with its bulb larger than usual. Holding it in the open still air, the temperature is marked: it is then warmed by the application of the hand, and the time is noted which it takes to sink back to the middle point. This I shall term the fundamental measure of cooling. The same observation is made on exposing the bulb to the impression of the wind, and I shall call the time required for the bisection of the interval of temperatures, the occasional measure of cooling. After these preliminaries, we have the following easy rule: Divide the fundamental by the occasional measure of cooling, and the excess of the quotient above unit, being multiplied by $4\frac{1}{2}$, will express the velocity of the wind in miles *per* hour. The bulb of the thermometer ought to be more than half an inch in diameter, and may, for the sake of portability, be filled with alcohol, tinged, as usual, with archil. To simplify the observation, a sliding scale of equal parts may be applied to the tube. When the bulb has acquired the due temperature, the zero of the slide is set opposite to the limit of the coloured liquor in the stem; and after having been heated, it again stands at 20° in its descent, the time which it thence takes until it sinks to 10° is measured by a stop-watch. Extemporaneous calculation may be avoided, by having a table engraved upon the scale for the series of occasional intervals of cooling."

WIND-Gall, a disease in horses and some other animals. It is a puffy kind of swelling or tumour, which yields to the pressure of the finger, but upon removing the pressure recovers itself, and pushes out as before. These swellings have been thus named from a false notion of their containing nothing but air or wind. These tumours are often seated on both sides of the back-sinew of a horse, above the fetlock on the fore-legs, but most frequently on the hind-legs. They are quite loose and detached from the parts on which they grow, and exhibit the same signs wherever they are met with, whether in the hocks or about the knees; for these swellings are not confined to the lower limbs only, but appear in any of those parts of a horse's body where the cellular membrane can be easily separated; and they exist, for the most part, without occasioning any pain. They are usually caused by riding on very hard roads, or on dry hilly grounds. Sometimes travelling horses, when they are worked too young, before the limbs are grown firm and vigorous, will have them. And Gibson observes, that they sometimes proceed from constitutional weakness, especially in bulky horses, that are somewhat under-limbed and fleshy about the fetlock-joint. These, it is said, have been known to have wind-galls without any strain, hard riding, or other ill usage of any kind.

It has been observed too, that when these tumours appear upon the hind-legs they never cause lameness, though such horses are often stiff behind after riding. When on the fore-legs they always make a horse go lame at first; but afterwards that tenderness goes off in a great measure, and they seldom go lame, but stiff, and inclinable to stumble. They generally recover, however, with a day's rest. Those flatulent swellings indeed that come in the ligaments of the hocks are always troublesome, disfigure the animal, and, unless speedily assisted, will cause incurable lameness. At first they are but small, but in time they grow to the size of a pullet's egg, perhaps, and push out on each side of the hollow of the hock. Swellings of the same kind also appear before the knee, where they often precede a diseased joint. Very small similar swellings under the fore part of the knee, in the interstices of both sides of the joint, are also dangerous; but these seldom happen, and are usually caused by some violent strain, especially when a horse falls down upon a descent with his whole weight upon his knees. The other flatulent swellings which horses are subject to seldom cause lameness, but are, for the most part, easily cured. We mean those that arise in the interstices of the large muscles of the hips and thighs, which are distended like little bladders filled with air. These come by strains and over-exertion; for draught-horses are the most subject to them.

Wind-galls that proceed from mere weakness are seldom curable, unless the constitution can be improved; but we often see horses that were subject to wind-galls when young, get the better of them as they advance in age. The methods of cure in these cases is by means of blistering, firing, and the use of astringent applications.

As these are enlargements of the capsules, or *bursæ mucose*, situated between the tendons, that contain an oily lubricating fluid for the prevention of friction and to facilitate motion, arising from long exertion producing inflammation of them, and an increased secretion of the contained fluid, they are capable of being easily removed in their beginning states, by rest and the use of blisters to the parts composed of cantharides and corrosive sublimate with olive oil; afterwards turning the animals out to grass or the straw-yard. Or where this cannot be permitted, the parts may be strengthened by the use of a flannel roller, made and continued wet by a wash composed of equal parts of strong vinegar and Goulard water, or the latter alone in some cases. If, however, the disease may have been neglected, recourse must be had to the hot iron; after which the blistering should be practised as before advised.

WIND-Gun. See **AIR-Gun**.

WIND-Hatch, in *Mining*, a term used to express the place at which the ore is taken out of the mines.

The word *hatch* is the general term used by the miners to express an opening from the surface into the mine, or in the attempting to find a mine.

Thus the word *essay-hatches* signifies the openings made in search of the trains of shoad-stones; and the *tin-hatch* in Cornwall is the name of the opening by which they descend into a tin-mine.

The word *wind-hatch* seems to be a corruption of *winder-hatch*; for at these places they have a winder conveying two buckets, the one constantly up, the other constantly down; the man below fills the bucket that descends; and when that which ascends full is emptied at the mouth of the hatch, the person who has the care of that part of the work, delivers it empty to go down again. Phil. Trans. N^o 69.

WIND-Hover, in *Ornithology*, the name of a species of hawk,

WIND-MILL.

hawk, called also by some the *flannel*, but more usually the *kefrel*, and known among authors by the names of the *tinnunculus* and *cenchris*.

WIND-Instruments, in *Music*, are instruments played by wind, chiefly by the breath; in contradistinction to stringed-instruments, and instruments of the *pulsative* kind.

The wind-instruments known to the ancients were, the *tibia*, *fistula*, or *syringa* of Pan, consisting of seven reeds, joined sidewise; also, *organs*, *tuba*, *cornua*, and the *lituus*. Those of the moderns are, the *flute*, *bagpipe*, *hautboy*, *trumpet*, &c. See INSTRUMENT, and MUSIC.

WIND-Mill, in *Mechanics*, a machine which is put in motion by the force of the wind. Wind-mills are in general applied to the purpose of grinding corn, but are occasionally used to give motion to machines for raising water, sawing-mills, or for other purposes. We shall in this article consider the wind-mill as a first mover, or *primum mobile*, which may be applied to many purposes.

The invention of wind-mills is not of very remote date. According to some authors they were first used in France in the sixth century; while others maintain that they were brought to Europe in the time of the crusades, and that they had long been employed in the East, where the scarcity of water precluded the application of that powerful agent to machinery.

The wind-mill, though a common machine, has some things in it more ingenious than is usually imagined. Add, that it is commonly allowed to have a degree of perfection, which few of the popular engines have attained to, and which the makers are but little aware of: though the aid of mathematics has furnished ample matter for its improvement.

The vertical wind-mill, which is the kind in most common use, consists of an axis or shaft A B, (*fig. 1. Plate II. Wind-Mill*), placed in the direction of the wind, and usually inclining a little upwards from the horizontal line. At one end of this, four long arms or yards, S, T, V, W, are fixed perpendicular to the axis, and cross each other at right angles; into these arms small cross-bars are mortised at right angles; and other long bars are joined to them, which are parallel to the length of the arms; so that the bars intersect each other in the manner of lattice-work, and form a surface, on which a cloth can be spread to receive the action of the wind. These are called the sails; they are in form of a trapezium, and are usually nine yards long and two wide.

The circular motion is produced by the obliquity of the planes of these surfaces, from the plane in which all the four arms are situated; by these means, when the wind blows in the direction of the axis, it does not impinge upon the sails at right angles to their surfaces, but strikes obliquely; hence the effort of the sail to recede from the wind, causes it to turn round with the common axis, and the four sails are all made oblique in the same direction, so as to unite their efforts for the common object.

That the wind may act with the greatest efficiency upon the sails, the wind-shaft must have the same direction as the wind. But as this direction is perpetually changing, some apparatus is necessary for bringing the wind-shaft and sails into their proper position: this is done by turning the axis and sails round in an horizontal direction. There are two methods of effecting this. In the old mills, like *fig. 1*, the whole of the mill or building which contains the machinery is sustained upon a vertical post, firmly fixed as a stand or foot, upon which the whole machine can be turned by a lever, to present the sails to any quarter of the horizon from whence the wind blows; and hence these are called post wind-mills, and are necessarily made of wood. The other kind, *fig. 2*, is called a

smock-mill, in which only the dome-cap or head, which contains the axis of the sails, and covers the great cog-wheel, turns round horizontally; the other parts of the machinery being contained in a fixed building, which rises up in form of a conical tower of masonry, and is surmounted by this moveable cap or dome, which is supported on rollers, so as to turn round easily.

As both the common methods of adjusting the wind-shaft require human assistance, it would be very desirable that the same effect should be produced solely by the action of the wind. This may be done by fixing a large wooden vane or weathercock at the extremity of a long horizontal arm, which lies in the same vertical plane with the wind-shaft.

By these means, when the surface of the vane and its distance from the centre of motion are sufficiently great, a very gentle breeze will exert a sufficient force upon the vane to turn the machinery, and will always bring the sails and wind-shaft to their proper position. This weathercock, it is evident, may be applied either to machines which have a moveable roof, or to those which revolve upon a vertical arbor. This method is practised in small machines; but a vane of sufficient power to turn a large mill about would be unwieldy. A much better method is therefore practised in the best mills, as we shall soon describe.

In a *post-mill* the building must necessarily be of small size, and it can only contain one pair of mill-stones. For this purpose, a large cog-wheel is fixed upon the main-shaft or axis of the sails; the cogs are placed in the face or flat surface of the wheel, and act upon the teeth of a pinion, which is fixed upon the vertical axis or spindle of the mill-stones. The mill-house is of a rectangular figure, but narrow in the direction which is presented to the wind: it is two stories high, the main-shaft and mill-stones being in the upper chamber, whilst the lower is only used to contain sacks of flour, and also to receive the post on which the mill turns round horizontally to face the wind. This post is a very strong tree, and is held perpendicularly by fixing it upon the middle of long timbers, which form a large cross on the ground, and are the basement of the whole mill. The post is fixed perpendicularly by means of several oblique braces, extending from the ground-cross to the middle part of the post; but ten or twelve feet of the upper end of the post must be round, and clear from the obstruction of the braces. This part of the post rises up through the middle of the lower chamber, in the floor of which a circular collar is formed, to surround the lower part of the post exactly. At the upper end of the post is a pivot or gudgeon, which enters into a socket fixed in the middle of the upper floor, and to one of the strongest cross-beams, because this beam must sustain the whole weight of the mill. In this manner, the whole mill can turn about upon the vertical post, but remains always in equilibrio. To make it firm, and prevent it from turning about at every moment, a strong framing is united by joints to the back part of the mill-house, and descends in a sloping direction till it touches the ground: this is furnished with steps, so that it serves as a broad ladder to ascend to the mill; but another use is to steady the mill, because the end of this frame, which is very heavy, rests on the ground, and short posts are fixed in a circle round the mill at regular intervals, to which the end of the ladder is fastened with cords. In order to turn the mill about, a rope is fastened to the end of the sloping ladder, and is carried up to the top of the mill in an inclined direction. By means of a strong lever, or a tackle of pulleys, this rope can be shortened, so as to lift up the ladder clear of the ground; and then, by pushing it like a long lever, the whole mill is turned round. To obtain more force, a small capstan is often provided to draw a rope

WIND-MILL.

a rope attached to the end of the ladder. This capstan is moveable, and is fastened at pleasure to any one of the posts which are fixed in the ground.

The internal mechanism of a post wind-mill is exhibited in *fig. 3. Plate II. Wind-Mill.* A H O is the upper room; H o z the lower one; A B the axis passing through the mill; S, T, V, W, the sails, covered with canvas, set obliquely to the wind, and turning round in the order of the letters in *fig. 1*; C the cog-wheel, having about forty-eight cogs, which carry round the lantern E, having eight or nine rounds, together with its spindle G N; K is the upper mill-stone, and L the lower one; Q R is the bridge supporting the axis or spindle G N; this bridge is supported by the beams c and X Y, wedged up at c and Q; z Y is the lifting-tree, which stands upright; a b and e f are levers, whose centres of motion are a and u; f g h i is a cord, with a stone, i: it goes about the pins g and h, to wind up and raise the stone at pleasure. The spindle t N is fixed to the upper mill-stone K, by a piece of iron called the rynd, and fixed in the lower side of the stone, which is the only one that turns about, and its whole weight rests upon a hard stone, fixed in the bridge Q R at N. The trundle E, and axis G t, may be taken away; for it rests by its lower part at t by a square socket, and the top runs in the edge of the beam w. By bearing down the end f of the lever f e, b is raised, which raises z Y, and this raises Y X, which lifts up the bridge Q R, with the axis N G, and the upper stone K; and thus the stones are set at any distance. The lower immovable stone is fixed upon strong beams, and is broader than the upper one: the flour is conveyed through the tunnel n o into a chest; P is the hopper, into which is put the corn, which runs along the spout r into the hole t, and so falls between the stones, where it is ground. The axis G t is square, which shaking the spout r, as it goes round, makes the corn run out; r s is a string going about the pin s, and serving to move the spout nearer to or farther from the axis, so as to make the corn run faster or slower, according to the velocity and force of the wind. And when the wind is great, the sails S, T, V, W, are only in part or one side covered; or perhaps only one half of two opposite sails. Toward the end B of the axis another cog-wheel may be fixed, with a trundle and mill-stones, like that already described; so that the same axis moves two stones at once; and when only one pair is to grind, the trundle E, and axis G t, are taken out from the other; x y l is a girt or gripe of pliable wood, fixed at the end x; and the other end l is tied to the lever k m, moveable about k; and the end m being put down, draws the gripe x y l close to the cog-wheel; and thus the motion of the mill is stopped at pleasure; p q is a ladder for ascending to the higher part of the mill; and the corn is drawn up by means of a rope, rolled about the axis A B, when the mill is at work.

The structure of the mill-stones, or grinding parts, is the same as the water-mills. See MILL.

It is plain that this construction confines all the machinery to the two chambers, or that part of the mill which is poised upon the vertical post; hence this kind of wind-mill is unfit for any other purposes than that of grinding corn, and for expressing oil, because there is so little room for the machinery. The Dutch, who are famous for wind-mills, make them sometimes with a very large post, which has a hole down the centre of it, like a trunk, and through this, a perpendicular axis passes to convey the power of the mill down into a building below, and upon the top of which, as a roof, the foundation-beams of the

post are fixed. (See *fig. 4.*) In this way, the mill is applied to saw wood, or to make paper, or any other purpose; but the construction is complicated, and less effective than the other kind of mill, in which only the head or top turns round, as we shall now describe.

The Smock-Mill.—This is the best kind of mill, because the building which contains the machinery may be made of any required dimensions, the sails and turning cap being all at the top of the house. *Fig. 3. in Plate I. Wind-Mill,* is a vertical section of one of these mills. K K are the walls of the house, and O O strong timbers forming a roof to it; upon these eight principal timbers H are erected, to form an octagonal pyramid of carpentry, the sides of which are filled up by diagonal bracing, and small uprights to nail the boarding to.

The four sails are fixed on an iron axis B N, by screwing them to an iron cross formed at one end of it. Two of these sails are marked A A; but the other two are endways, and cannot be seen. Upon the axis within the mill the cog-wheel C is fixed; and this turns a trundle or lantern D, fixed on the upper end of a strong vertical shaft, E E, extending from the top to the bottom of the mill, to turn the machinery: on the lower end of it is a large wheel, f f, which turns two pinions, g g, upon the spindles of the mill-stones h h. These are on the same construction as those described in our article MILL, to which we refer. At l is a wheel upon the main axis, giving motion to a pinion on a horizontal shaft or roller, k, which has a rope wrapped upon it, to wind up the sacks of corn. The wheel l also turns a similar horizontal axis with several wheels, to receive endless ropes for turning the bolting and dressing machines.

We will now enter more fully into the mechanism of the upper part of the mill, which is called its head or cap, marked G, and contains the axis B N. This is supported upon bearings, one being near its sails, and the other at its extreme end, as is shewn in *fig. 5. Plate II. Wind-Mill,* which is an horizontal section of the head, shewing the circular kirk, or wooden ring, K, and the framing which is bolted upon it to support the axis.

The construction of the axis is shewn in *fig. 6.* of the same plate. It consists of an octagonal iron shaft with two cylindrical necks at e and d, where it rests upon its bearings. At the end it has a kind of box, which has two mortises, e and f, through it in perpendicular directions to receive the sails. At the back of one of these mortises, and the front of the other, a projecting arm is left in the casting to receive screw-bolts, which hold the sails fast in the mortises. The cog-wheel is fixed on by bolting its arms against a flanch C, cast on the axis. The sails are braced by a rope-stay to each arm, proceeding from the end of a pole, which is fixed at the end of the cast-iron axis. Each sail is formed of a sail-cloth, spread upon a kind of lattice-work or framing, composed of rails mortised into the arms of the sails. The plane of this frame is inclined to the plane of the sails' motion at such an angle, that the wind blowing in the direction of the axis acts upon the sails as inclined planes, and turns them about with a power proportionate to the size of the sails and force of the wind. It is necessary, as the wind changes its direction, to turn the sails about, that the axis may be always in the direction of the wind. (See *fig. 3. Plate I.*) This motion is effected by turning the head of the mill round upon the fixed part, on a circle or kirk at the top of the frame composing the house of the mill. At the bottom of the frame of the wood-cap is a circular or moveable kirk, between which and the fixed kirk a number of rollers are placed; and the moveable kirk of the cap lies upon these rollers, which are kept equidistant

WIND-MILL.

equidistant from each other by their centre-pins being fitted into a circular hoop : by these means, though the head of the mill with the wheels and sails weigh several tons, they can be made to turn round to face the wind by a slight power.

The head is contrived to turn itself about whenever the wind changes in the following manner :—A small pair of sails, or fans, *M*, are fixed up in a frame *L*, projecting from the back of the head : it has a pinion of ten leaves upon its axis, engaging in a wheel of 60 teeth upon an inclined axis *b* ; and this has a pinion *d* of 12 leaves at the other end of it, turning a bevelled wheel of 72 teeth upon a vertical iron axis, at the lower end of which is a pinion *e* of 11 teeth : this works in a circle of 120 cogs, fixed round on the outside of the fixed kirk. By these means, whenever the fan *M* is turned, it moves the head of the mill slowly round, and with proportionate power.

Now if ever the wind varies in the least from the direction of the main shaft of the sails, it acts obliquely upon the vanes of the fan, and turns them round, at the same time setting the head right again, so that the axis points to the wind. But when the axis is in this situation, the wind blows in the planes of the vanes of the fan, and has no effect upon them. The head of the mill is kept firmly in its place when it turns about by rollers ; the axles of which are bolted to the inside of the framing of the head, and the rollers apply to the inside of the fixed kirk : there are four of these rollers. The pivot at the upper end of the vertical shaft is supported in a bearing bolted to a cross-beam in the framing of the head of the mill ; and this is fixed precisely in the centre of the head, that it may not vary in its situation as the head turns round. Many other things are so evident in the drawing as to need little farther explanation ; such as the different floors of the building, and the circular gallery, *I I*, all round the mill, for the miller to go round to take the cloth off the sails in high winds, or when the mill is to stop. This is done by untying the cloth at the extremity of the sail, and twisting it up like a rope ; then tying the end of it again to the lattice, in which state it presents no surface to the wind. At *k* is a roller turned round by a wheel *l*, fixed on the middle part of the vertical shaft : it is used to draw up the sacks of corn from the bottom of the mill into the upper part, which is used as a store-house for the corn, being divided into as many compartments as the miller requires. The mill-stones are made the same as those used in water-mills. A pair of regulating balls are attached to the upper part of the mill-stone spindle, to regulate the velocity of the mill. The manner of applying this regulator is explained in *fig. 5. Plate II. Wind-Mill.* The lower end of the iron spindle *F* is fitted to a square, formed on the top of the mill-stone axis, and the pinion *g g* is fixed on the upper end, to give motion to the stones : immediately beneath the pinion two rods are jointed, hanging downwards, having a heavy iron ball, *l*, fixed fast on the lower end of each : two links are jointed to the arms at *m*, and suspend a collar, which is capable of sliding freely up and down upon the spindle *F*. It is evident that when the balls fly out from the spindle by their centrifugal force, that the collar will be elevated, and the contrary when the balls approach the spindle. The sliding collar is embraced by a fork formed at the end of a steelyard, lying horizontal, and suspended by the rod *p* as a fulcrum ; an iron rod *q* descends from the extreme end of the steelyard, having its lower end formed to a hook, by which it is connected with a lever, *r*, whose fulcrum is *s* ; this, by an iron rod *t*, suspends one end of the beam called the bridge, on which the lower pivot of the mill-stone axis rests, the other end bearing on a fulcrum or centre. Now it follows from this arrangement of levers, that by elevating the forked end

of the steelyard, or the sliding collar, that the spindle of the stones will be suffered to descend a very minute quantity. This regulates the velocity of the mill, because when the wind increases, and the motion of the mill is accelerated, the balls fly out by the centrifugal force ; this lets the upper stone down nearer to the lower, thereby increasing the resistance to the mill, and counteracting the increased force of the wind. On the other hand, if the wind falls, and the mill moves more slowly in consequence, the balls fall together, and let down the sliding collar ; this raises the stone up, and increases the distance between them, thereby diminishing the resistance ; for this purpose, a weight *o* (*fig. 5.*) is hung upon the steelyard, sufficient to elevate the stone whenever the closing of the balls and consequent descent of the collar will permit it to do so. There are several notches made in the steelyard for different positions of the fulcrum *p* and rod *q* ; by means of these the quantity of the regulation can be adjusted to the following rule. If when the wind blows stronger the mill goes slower, contrary to the effect expected, it shews that the regulation is too active ; then increase the leverage of the balls by shortening the distance between the fulcrum *p* of the steelyard and the suspension of the rod *q*, by shifting either of them into different notches. On the contrary, if the mill goes much faster when the wind increases, it shews that the regulation does not act sufficiently ; then increase the distance between the rod *q* and the fulcrum *p*. If the whole limits of the notches in the steelyard should not be sufficient to effect this, the acting length of the lever *r s* must be increased or diminished by removing its fulcrum *s* to a greater or lesser distance from the suspending-rod *t* ; by means of this contrivance the miller is enabled, without much inconvenience, to regulate the velocity of the stones to that degree which is found best for reducing the greatest quantity of grain to flour, without damaging it by heating, as is the case when the stones move too quick.

Theory of the Motion of a Wind-Mill, with the Position of its Sails or Vanes.—The angle which the surfaces of the sails are to make with their common axis, that the wind may have the greatest effect, or the degree of weathering, as the millwrights call it, is a matter of nice inquiry, and has much employed the thoughts of the mathematicians.

To conceive why a wind-mill moves at all, the theory of compound motions must be supposed. A body moving perpendicularly against any surface, strikes it with all its force. If it move parallel to the surface, it does not strike it at all ; and if it move obliquely, its motion, being compounded of the perpendicular and parallel motion, only acts on the surface, considered as it is perpendicular, and only drives it in the direction of the perpendicular. So that every oblique direction of a motion is the diagonal of a parallelogram, whose perpendicular and parallel directions are the two sides. Add, that if a surface, which, being struck obliquely, has only received the perpendicular direction, be fastened to some other body, so as that it cannot pursue its perpendicular direction, but must change it for some other ; in that case, the perpendicular itself becomes the diagonal of a new parallelogram, one of whose sides is the direction which the surface may follow ; and the other, that which it cannot.

Thus, a rudder fastened obliquely to the keel of a vessel, being struck by the current of water parallel to the keel, and, of consequence, obliquely with regard to itself ; it will appear, by drawing the line of perpendicular impulse, that it tends to tear the rudder from the keel, and to carry it away : and that this direction, perpendicular to the rudder,

WIND-MILL.

der, is oblique to the keel. The rudder, then, would be carried off in an oblique direction; but as, in reality, it is so secured, that it cannot be torn and carried off, we are only to consider, in this compound motion, that of the two directions wherewith it can move without being torn from the keel; and leave the other, which would tear it off, as useless.

Now, the direction in which it can move without parting from the keel, is that which carries it circularly about its extremity, as about a centre. So that the effect of the oblique impulse of the water on the rudder is reduced, first to a perpendicular impression, which is again reduced to the mere turning of the rudder round; or, if the rudder be immoveable, to the turning of the vessel. Now, in an oblique and compound motion, where only one of the directions is of service; the greater ratio the other has to it, the less effect will the motion have, and *vice versa*. In examining the compound motions of the rudder, we find, that the more oblique it is to the keel, the ratio of the direction that serves to turn it to the other is the greater. But, on the other hand, the more obliquely it is to the keel, and, of consequence, to the course of the water which is supposed parallel to it, the more weakly it strikes. The obliquity of the rudder, therefore, has, at the same time, both an advantage and a disadvantage; but as those are not equal, and as each of them is still varying with every different position of the rudder, they become complicated variously; so that sometimes the one prevails, and sometimes the other.

It has been a point of inquiry to find the position of the rudder, in which the advantage should be the greatest. M. Renau, in his famous theory of the working of ships, has found, that the best situation of the rudder is, when it makes an angle of fifty-five degrees with the keel. See RUDDER.

If, now, a wind-mill, exposed directly to the wind, should have its four sails perpendicular to the common axis in which they are fitted, they would receive the wind perpendicularly; and it is visible that impulse would only tend to overturn them. There is a necessity, therefore, to have them oblique to the common axis, that they may receive the wind obliquely.

For the greater ease, let us only consider one vertical sail. The oblique impulse of the wind on this sail is reducible to a perpendicular impulse; and that direction, as the sail cannot absolutely keep to it, is compounded of two; one of which tends to make it turn on its axis, and the other to fall backwards. But it is only the first of these directions that can be obeyed. Of consequence, the whole impulse of the wind on the sail has no other effect but to make it turn from right to left, or from left to right, as its acute angle turns this way or that. And the structure of the machine is so well contrived, that the three other sails are determined, from the same causes, to move the same way.

The obliquity of the sails, with regard to their axis, has precisely the same advantage and disadvantage with the obliquity of the rudder to the keel. And M. Parent, seeking, by the new analysis, the most advantageous situation of the sails on the axis, finds it precisely the same angle of fifty-five degrees.

For the farther illustration of this point, let A B (*Plate II. Wind-Mill, fig. 7.*) be the axis of the mill, C D a sail, and its angle of obliquity (*viz.* that which it makes with the axis) be E C G; then if G C be the force of the wind in the direct position of the sail, G E (the sine of the angle of incidence G C E) will be the force of the wind in its oblique position; but the force of G E is resolvable into two

others, E F and G F; of which the latter, being parallel to the axis, avails nothing in turning the sails about it; but the other, E F, being perpendicular to it, is wholly spent in compelling the sail to turn round. The force of the wind on the sail will be as the square of the sine of incidence, or as G E²; and if the area of the sail, and the velocity of the wind, be supposed constant, the force of the wind in the direct position will be to that in the oblique one, as G C to G E²; but when G E is the whole force, that part which turns the sail is represented by E F;

$$\text{and } G E : E F (:: G C : C E) :: G E^2 : \frac{C E \times G E^2}{G C}$$

= to the force which turns the sail, when the whole

$$\text{force is represented by } G E^2. \text{ This expression } \frac{C E \times G E^2}{G C}$$

begins from nothing, when the angle of incidence begins to be oblique, and increases with the obliquity of the said angle to a certain number of degrees; because that part of the force which is parallel to the axis, becomes less in proportion to that which is perpendicular to it; but after it has passed this limit, it again decreases, and becomes nothing, when the angle of incidence vanishes. There is, therefore, one certain position of the sail, in which the force of the wind upon it is a *maximum*. In order to find this, put radius G C = a, E C = x; and we have G E² = a a - x x, and consequently the

$$\text{force } \frac{C E \times G E^2}{G C} = \frac{a a x - x x x}{a}, \text{ which must be a } \textit{maxi-}$$

mum: therefore its fluxion $a a \dot{x} - 3 x^2 \dot{x} = 0$: whence

$$a a = 3 x x, \text{ and so } x = \sqrt{\frac{a a}{3}} = (\text{in logarithms})$$

$$\frac{20.000000 - 0.477121}{2} = 9.761439, \text{ which is the loga-}$$

rithmic sine of the angle $35^\circ 16' = C G E$; and therefore the angle E C G = $54^\circ 44'$, when the force of the wind is a *maximum*. Thus, also, if *lm* (*fig. 7.*) parallel to the axis Q M, be equal to a, and represent the whole force of the wind on the sail; this force is reduced to *ln*, and this again to *no*, which acts perpendicularly to the axis, and turns the sail. This force, putting *mn* = x,

$$\text{is expressed by } \frac{a a x - x^3}{a}, \text{ and thus, as before, when it}$$

$$\text{is a } \textit{maximum}, x = \sqrt{\frac{a a}{3}} = a \sqrt{\frac{1}{3}}; \text{ and the angle}$$

lmn = $54^\circ 44'$. *Martin's Phil. Brit. vol. i. p. 220, vol. ii. p. 212.*

This angle, however, is only that which gives the wind the greatest force to put the sail in motion, but not the angle which gives the force of the wind a *maximum* upon the sail when in motion: for when the sail has a certain degree of motion, it yields to the wind; and then that angle must be increased, to give the wind its full effect. Mr. Maclaurin, in his *Fluxions*, vol. ii. p. 734. has shewn how to determine this angle.

It may be observed, that the increase of this angle should be different, according to the different velocities from the axis to the extremity of the vane or sail. At the axis it should be $54^\circ 44'$, and thence continually increase, giving

the vane a twist, and so causing each rib of the vane to lie in a different plane.

It is observed, that the ribs of the vane or sail ought to decrease in length from the axis to the extremity, giving the vane a curvilinear form; so that no part of the force of any one rib be spent upon the rest, but all move on independent of each other. The twist above-mentioned, and the diminution of the ribs, are exemplified in the wings of birds. As the end of the sail nearest the axis cannot move with the same velocity which the tips or farthest ends have, although the wind acts equally strong upon them, Mr. Ferguson (Lect. on Mechanics, p. 52.) suggests, that perhaps a better position than that of stretching them along the arms directly from the centre of motion, might be to have them set perpendicularly across the farther ends of the arms, and there adjusted lengthwise to the proper angle. For, in that case, both ends of the sails would move with nearly the same velocity; and being farther from the centre of motion, they would have so much the more power, and then there would be no occasion for having them so large as they are generally made; which would render them lighter, and, consequently, there would be so much the less friction on the thick neck of the axle, when it turns in the wall.

M. Parent considered what figure the sails of a wind-mill should have, to receive the greatest impulse from the wind; and he determined it to be a sector of an ellipsis, whose centre is that of the axis, or arbor, of the mill; and the little semi-axis the height of thirty-two feet: as for the greater, it follows necessarily from the rule that directs the sail to be inclined to the axis, in an angle of 55 degrees.

On this foundation he assumes four such sails, each of which is one-fourth of an ellipsis; which, he shews, will receive all the wind, and lose none, as the common ones do. These four surfaces, multiplied by the lever with which the wind acts on one of them, express the whole power the wind has to move the machine, or the whole power the machine has when in motion.

The same manner of reasoning, applied to a common wind-mill, whose sails are rectangular, and their length about five times their breadth, shews, that the elliptic wind-mill has about seven times the power of the common one.

A wind-mill with six elliptic sails, he shews, would still have more power than one with only four. It would only have the same surface with the four, since the four contain the whole space of the ellipsis as well as the six. But the force of the six would be greater than that of the four, in the ratio of 245 to 231. If it were desired to have only two sails, each being a semi-ellipsis, the surface would be still the same; but the power would be diminished by near one-third of that with six sails, because the greatest of the sectors would much shorten the lever with which the wind acts.

Best Form and Proportion of rectangular Wind-Mills.—As elliptical sails would be something so new, that there is little room to expect they will come into common use, the same author has considered which form, among the rectangular ones, will be the most advantageous. And by the method *de maximis et minimis*, he finds it very different from the common ones.

The result of this inquiry is, that the width of the rectangular sail should be nearly double its length; whereas the length is usually made almost five times the width. Add, that as we call length the dimension which is taken from the centre of the axis, the greatest dimension of the new rectangular sail will be turned toward the axis, and the

smallest from it; quite contrary to the position of the common sails.

The power of a wind-mill with four of these new rectangular sails, M. Parent shews, will be to the power of four elliptic sails, nearly as 13 to 23; which leaves a considerable advantage on the side of the elliptic ones; yet will the force of the new rectangular sails be considerably greater than that of the common ones.

M. Parent likewise considers what number of the new sails will be most advantageous; and finds, that the fewer the sails, the more surface there will be, but the less power. The ratio of the power of a wind-mill with six sails will be to another with four, nearly as 14 to 13. And the power of another with four will be to that with two, nearly as 13 to 9.

For a variety of curious experiments and observations concerning the construction and effects of wind-mill sails, by the ingenious Mr. Smeaton, see Phil. Trans. vol. ii. p. 138, &c.

Mr. Smeaton's experiments did not realize M. Parent's theory; for he found the sails fixed at the angle of 55 degrees with the axis, to be the least advantageous of any which he tried; but if the sails are included from 72 to 75 degrees from the axis, or 15 to 18 degrees to the place of their motion, the greatest effect will be produced that can be when the sails are plane surfaces.

He also found, that the elliptical sails, which intercept the whole cylinder of wind, do not produce the greatest effect, for want of proper interstices for the wind to escape.

The following maxims, deduced by Mr. Smeaton from his experiments, contain the most accurate information upon the subject.

Maxim 1.—The velocity of wind-mill sails, whether unloaded or loaded, so as to produce a maximum effect, is nearly as the velocity of the wind, their shape and position being the same.

Maxim 2.—The load at the maximum is nearly, but somewhat less than, as the square of the velocity of the wind, the shape and position of the sails being the same.

Maxim 3.—The effects of the same sails at a maximum are nearly, but somewhat less than, as the cubes of the velocity of the wind.

Maxim 4.—The load of the same sails at the maximum is nearly as the squares, and their effects as the cubes of their number of turns in a given time.

Maxim 5.—When sails are loaded, so as to produce a maximum at a given velocity, and the velocity of the wind increases, the load continuing the same: 1st, The increase of effect, when the increase of the velocity of the wind is small, will be nearly as the squares of those velocities. 2^{dly}, When the velocity of the wind is double, the effects will be nearly as 10 to 27½. But, 3^{dly}, When the velocities compared are more than double of that where the given load produces a maximum, the effects increase nearly in the simple ratio of the velocity of the wind.

Maxim 6.—In sails where the figure and positions are similar, and the velocity of the wind the same, the number of turns in a given time will be reciprocally as the radius or length of the sail.

Maxim 7.—The load at a maximum that sails of a similar figure and position will overcome, at a given distance from the centre of motion, will be as the cube of the radius.

Maxim 8.—The effects of sails of similar figure and position are as the square of the radius.

Maxim 9.—The velocities of the extremities of the sails, in all their usual positions, when unloaded, or even loaded

WIND-MILL.

loaded to a maximum, are considerably quicker than the velocity of the wind.

Rules for modelling the Sails of Wind-Mills.—Fig. 4. Plate II. *Wind-Mill*, is a front view of one of the four sails of a wind-mill. The letters of reference will serve to explain the terms made use of in the following description.

1. The length of the arm or whip A A, reckoned from the centre of the great shaft B, to the outermost bar 19, governs all the rest.

2. The breadth of the face of the whip A, next the centre, is one-thirtieth of the length of the whip; its thickness at the same end is three-fourths of the breadth; and the back-side is made parallel to the face for half the length of the whip, or to the tenth bar; the small end of the whip is square, and as its end is one-sixtieth of the length of the whip, or half the breadth at the great end.

3. From the centre of the shaft B, to the nearest bar 1 of the lattice, is one-seventh of the whip; the remaining space of six-sevenths of the whip is equally divided into nineteen spaces, so as to make nineteen bars; one-ninth of one of these spaces is equal to the mortises for the bars, the tenons of which are made square where they enter and go through the whip, and consequently the mortises must be square also.

4. To prepare the whip for mortising, strike a gage-score at about three-fourths of an inch from the face on each side, and the gage-score, on the leading side 4, 5, will give the face of all the bars on that side; but on the other side, the faces of all the bars will fall deeper than the gage-score, according to a certain rule. To find the space to be set off for this purpose for each bar, construct a scale in the following manner.

5. Extend the compasses to any distance at pleasure, so that six times that extent may be greater than the breadth of the whip at the seventh bar; set those six spaces off upon a straight line for a base, at the end of which raise a perpendicular; set off three spaces upon the perpendicular, and divide the two spaces that are farthest from the base line into six equal parts each, so that this quantity of two spaces may be equally divided into twelve spaces marked out by thirteen points; from each of these points draw a line to the opposite end of the base, as so many rays to a centre, and the scale is finished.

6. To apply this scale to any given case, set off the breadth of the whip at the last bar, (that is, the bar at the extremity of the sail,) from the centre of the scale along the base towards the perpendicular; and at this point raise a perpendicular to cut the ray nearest to the base; also set off the breadth of the whip at the seventh bar in the same manner, and at this point erect another perpendicular to cut the thirteenth radius. From the intersection of the perpendicular (drawn upon the breadth of the last bar) with the first of the thirteen radii, to the intersection of the other perpendicular with the thirteenth radius, draw an oblique line cutting all the rest, and the distances of each of these last-mentioned points of intersection from the base line is the space which the face of each bar is distant from the gage-line on the driving side.

7. These distances give a different set-off for each bar till the seventh, which same must be set off for all the rest to the first.

8. The mortises must be square to the leading side of the whip.

9. When the mortises are cut, let the face of the whip be sloped off so as to agree with the face of the bars in every part.

10. Two-fifths of the whip are the length of the last or longest bar.

11. Five-eighths of the longest bar must be on the driving side of the whip, and three-eighths on the leading side, each being reckoned from the middle of the whip.

12. The proportion of the mortises already given determines the size of the bars at the mortises, but their thickness must be diminished each way, so as to be only one-half at the ends; but the face must be kept of equal breadth all the way.

13. The leading side goes no farther than the fourth bar, and there only projects one-third of the projection of the last bar.

14. All the bars on the driving side are made hollowing in the arch of a circle, which begins to spring one-third of the length of the bars on the driving side from the whip; and the sweep is such, that if a straight line is applied to the face of the bar from the whip to the end, the face of the bar should leave the straight line about the breadth of the bar.

15. There ought to be three uplongs, as 3, 2, 10, *fig. 4*, to the driving, and two to the leading side, as at 5, 4, to strengthen the lattice.

Self-regulating wind-mills are those which adapt themselves to the irregularities of the wind, by diminishing or increasing the surface on which the wind can act to turn them round. If the wind increases in force, the surface exposed to its action is diminished; on the contrary, if it decreases in force, the surface will be increased in the same proportion, so as in some measure to render their motion uniform.

The following self-regulating wind-mill is stated as the invention of Mr. Andrew Mickle in 1772, the inventor of the threshing-machine. The length of the sail was divided into eleven compartments, by the bars forming a number of oblong openings, which were each filled up by a square frame of wood covered with canvas, and mounted on pivots at their ends; one pivot turning in a hole in the whip, and the other in the bar which lies parallel to it, in the manner of a Venetian blind: the pivots were not placed in the middle of the breadth of the frames, but at one-third from that edge, towards the shaft or axis of the sails. On the end of each pivot which enters the whip a small roller is fixed, round which a chain passes, and its end is attached to a steel spring, placed at right angles to the whip, and in the direction of the length of the canvassed frames. Now, if the wind blows too hard, it acts to turn the frames edgewise, in which case the wind passes through the sails, and exerts less force to turn them round; but as soon as the wind becomes moderate, the steel spring brings up the frames into a plane, presenting their whole surface to its action. A rod of iron extends the whole length of the whip, and is connected with the several springs, to afford the means of strengthening or diminishing their action, according to the season of the year. This rod was formed into a screw at its outer extremity, and a nut put on to enable the miller to adjust the strength of the springs conveniently, from the circular gallery surrounding the outside of the mill.

Mr. William Cubit of North Walsham, in the county of Norfolk, took out a patent, in 1807, for a method of equalizing the motion of wind-mill sails. It is similar to Mr. Mickle's, in the sails being made like a Venetian blind; but instead of the springs, he applied racks and pinions on the ends of the blind pivots, and a sliding rod, which passed in a small hole made through the length of the axis of the sails; the end of this rod within the mill was

WIND-MILL.

made into a rack, working in a wheel upon which a weight was hung. By this means, when the wind blows too hard, the blinds turn upon their pivots, and by the racks draw out the rod which passes through the axis, and raise the weight; but as soon as the wind abates, the weight brings the blinds to their former position.

A patent was granted in 1804 to Mr. John Bywater of Nottingham, for a method of clothing and unclothing the sails of wind-mills while in motion. The invention consists in a manner of rolling or folding up, and unfolding again, the cloths of common wind-mill sails while in motion. It is effected by placing a long roller in the direction of the length of the whip round which the cloth is rolled; the inner end of the roller is furnished with a pinion, which engages in the teeth of a circular ring of cogs fixed to the shaft-head, close behind the back-stocks, with the liberty of turning round independent of the shaft. Another roller is placed at the back-side of the sail, round which several cords pass, and are conveyed over pulleys at the edge of the sail, and then made fast to the cloth at different distances along its length. The object of this second roller is to clothe the sail, in the same manner as the first-mentioned roller unclothed it. The inner end of the back roller is furnished with a bevelled pinion, which acts in the teeth of a ring of cogs placed concentric with the one before described, which has also the liberty of turning round independent of the shaft. Suppose the sails to be completely clothed, and turning round by the wind, the two rings of cogs revolve with the axis, and therefore produce no effect on the pinions; but if the wind blows too violent, and it becomes necessary to partly unclothe the sails, the miller pulls a cord which is connected with a lever in the head of the mill. This lever comes in contact with a projection on the ring of cogs belonging to the rollers, upon which the cloth winds. Now it is evident, that if the ring of cogs is held fast, and the sails continue to revolve, it will cause the pinions to turn round and roll up the cloth upon the rollers; on the contrary, if the wind falls, the sails will require to be more clothed, which is effected by the same lever being moved farther, so as to quit the ring of cogs it held before, and hold the other fast, which will put the rollers at the back of the sails in motion, and by winding the cords upon them, draw the cloth off the sail-roller, which increases the surface for the wind to act upon. We have not entered into the minute details of this invention, as given in the patent, for it would have exceeded our limits, but only given a sufficient description to enable a person to understand the means of effecting the regulation.

Horizontal Wind-Mills.—These are of various kinds; but only one kind that we know of has been put to any valuable use.

Horizontal wind-mills were a favourite speculation a century ago; and the *Theatrum* of the celebrated Leopold contain a great variety, but they are all upon one or other of two principles. In one of these, a very large wheel, like a water-wheel, is mounted with its axis in a perpendicular direction. It consists of several circular wheels fixed upon the axis; and it has large boards or vanes fixed parallel to its axis, and arranged at equal distances round the circular wheels. Upon these vanes the wind can act to blow the wheel round; but if the wind were to act upon the vanes at both sides of the wheel at once, it would have no tendency to turn the wheel round; hence one side of the wheel must be sheltered from the wind, whilst the other is submitted to its full action. For this purpose, the whole wheel is inclosed within a large cylindrical framing of wood,

which is furnished with doors or shutters on all sides to open at pleasure, and admit the wind, or to shut and stop it. If all the shutters on one side are open, whilst all those on the opposite side are shut, the wind, acting with undiminished force on the vanes at one side, whilst the opposite vanes are under shelter, turns the mill round; but whenever the wind changes, the disposition of the open vanes must be altered, to admit the wind to strike upon the vanes of the wheel in the direction of a tangent to the circle in which the vanes move. A horizontal wind-mill is thus described in Leopold's *Theatrum Machinarum* for grinding corn with one pair of stones. A strong upright axis is so poised on a pivot at the lower ends, and sustained in a collar or bearing, as to turn round. Into this several long arms are fixed, in the manner of radii, and at the extreme ends of each arm a vane is fixed, to receive the action of the wind. These vanes are made of two or more moveable leaves, which close up flat like a book, when they are at that side of the circle which moves in a direction to advance towards the wind; so that only the edges of the boards are opposed to the wind; but when these vanes arrive at the opposite side of the wheel, so that the wind blows upon them, the leaves fly open, and expose their full surfaces to the wind, and receive the impulse thereof.

A horizontal wind-mill is described by Dr. Hooke in the *Philosophical Collections* for 1681. It consisted of four vanes mounted upon vertical axes, and arranged round in a circle by the upper and lower pivots of the vanes being received into holes in the rims of two horizontal wheels fixed upon the same vertical shaft. The vanes were disposed in such a manner, that on one side of the wheel each vane presented its surface to the wind, whilst the one on the opposite stood edgeways, so as to move through the air without much resistance. This was effected by cog-wheels placed on the lower pivots of the vanes, and so arranged, that as one vane turned round upon its pivots, the whole number moved together, and the motion was given to them by a cog-wheel fixed fast to the framing over the wheel, but concentric with it. This wheel communicated, by means of an intermediate wheel, with the wheels on the axes of the vanes.

The action of this machine is as follows:—Suppose the wind blowing at the wheel; it acts against that vane which is at right angles to its motion, to turn the wheel round upon its axis. The opposite vane presenting its edge to the wind opposes very little resistance. The motion of the wheel upon its axis turns the vanes round upon their pivots, by means of the fixed cog-wheel before described; so that by the time that one has passed out of the direction of the wind, another arrives in the same perpendicular position; and when the wheel has made half a revolution, the vane which stood edgeways will be perpendicular to the wind, and the one which before stood perpendicular will be edgeways; thus a continued motion is produced without the wheel being cased up.

Horizontal wind-mills, which are inclosed in a house with blinds on all sides, are very fully described in Jacob Leopold's *Theatrum Machinarum*, 1724; but we believe they were first practised in this country by captain Hooper, who erected one at Margate, and another at Battersea. The latter is upon a very large scale, and is used for grinding corn; but at present it does not work with much advantage, as the repairs are more considerable in proportion to the power it exerts, than in the mills with sails constructed in the common manner.

In *Plate Wind-Mill*, fig. 1, is an upright section, and fig. 2.

a plan of the horizontal mill erected at Margate by captain Hooper. H H are the side walls of an octagonal building which contains the machinery. These walls are surmounted by a strong timber-framing G G, of the same form as the building, and connected at top by cross-framing to support the roof, and also the upper pivot of the main vertical shaft A A, which has three sets of arms, B B, C C, and D D, framed upon it at that part which rises above the height of the walls. The arms are strengthened and supported by diagonal braces, and their extremities are bolted to octagonal wooden frames, round which the vanes or floats E E are fixed, as seen in outline in *fig. 2*, so as to form a large wheel resembling a water-wheel, which is less than the size of the house by about eighteen inches all round. This space is occupied by a number of vertical boards or blinds F F, turning on pivots at top and bottom, and placed oblique, so as to overlap each other, and completely shut out the wind, and stop the mill, by forming a close case surrounding the wheel; but they can be moved all together upon their pivots to allow the wind to blow in the direction of a tangent upon the vanes on one side of the wheel, at the time the other side is completely shaded or defended by the boarding. The position of the blinds is clearly shewn at F F, *fig. 2*. At the lower end of the vertical shaft A A, a large spur-wheel *aa* is fixed, which gives motion to a pinion *c*, upon a small vertical axis *d*, whose upper pivot turns in a bearing bolted to a girder of the floor N. Above the pinion *c*, a spur-wheel *e* is placed, to give motion to two small pinions *f*, on the upper ends of the spindles *g* of the mill-stones *b*. Another pinion is situated, at the opposite side of the great spur-wheel *a a*, to give motion to a third pair of mill-stones, which are used when the wind is very strong; and then the wheel turns so quick, as not to need the extra wheel *e* to give the requisite velocity to the stones. The weight of the main vertical shaft is borne by a strong timber *b*, having a brass box placed on it to receive the lower pivot of the shaft. It is supported at its ends by cross-beams mortised into the upright posts *bb*, as shewn in the plan, *fig. 2*. A floor, or roof, I I, is thrown across the top of the brick building, to protect the machinery from the weather; and to prevent the rain blowing down the opening through which the shaft descends, a broad circular hoop K is fixed to the floor, and is surrounded by another hoop or case L, which is fixed to the arms D D of the wheel. This last is of such a size, as exactly to go over the hoop K, without touching it when the wheel turns round. By this means, the rain is completely excluded from the upper room M, which serves as a granary, being fitted up with bins *mm*, to contain the different sorts of grain which is raised up by the sack-tackle. A wheel *i* is fixed on the main shaft, having cogs projecting from both sides. Those at the under side work into a pinion on the end of the roller *k*, which is for the purpose of drawing up sacks. Another pinion is situated above the wheel *i*, which has a roller projecting out over the flap-doors seen at *p*, in the *fig. 2*, to land the sacks upon. The two pinions *mm*, *fig. 2*, are turned by the great wheel *aa*, and are for giving motion to the dressing and bolting machines, which are placed upon the floor N, but are not shewn in the drawing, being exactly similar to the dressing-machines used in all flour-mills. The cogs upon the great wheel *a* are not so broad as the rim itself, leaving a plain rim about three inches broad. This is encompassed by a broad iron hoop, which is made fast at one end to the upright post *b*; the other being jointed to a strong lever *n*, to the extreme end of which a purchase *o* is attached, and the fall is made fast to iron pins on the top of a frame fixed to the ground.

This apparatus answers the purpose of the brake or gripe used in common wind-mills to stop their motion. By pulling the fall of the purchase *o*, it causes the iron strap to embrace the great wheel, and produce a resistance sufficient to stop the wheel. The mill can be regulated in its motion, or stop entirely, by opening or shutting the blinds F, which surround the fan-wheel. They are all moved at once by a circular ring of wood situated just beneath the lower ends of the blinds upon the floor I I, being connected with each blind by a short iron link. The ring is moved round by a rack and spindle, which descend into the mill-room below, for the convenience of the miller.

A sort of wind-mill has been long much employed in Portugal, in which, from the difference in the construction of the sails, it is supposed by some, as lord Somerville, who has inspected it when working, to possess a superiority in having the broad part of the sail at the end of the levers or booms; in consequence of which equal resistance is overcome with less length of branches: and that from this shortness a considerable saving is made in the timber of both the booms and spindles, as well as in the height, first cost of the mills, and their future repairs.

The advantages of making use of these sorts of wind-mills in preference to others are, that as there are four booms, as well as four masts for the sails, they are capable of being more easily braced out to the wind, and in case of a sudden gale or gust of it, are more easily cast loose than in those of the common construction; and that as the sails in these mills are placed in the best possible direction by the booms, it is presumed that a wind-mill built on this plan and principle will do more work than any common wind-mill with an equal quantity of canvas.

These sorts of mills have also lately been very much improved by constructing and disposing those surface parts upon which the wind is intended to act, in such a particular manner, as that by alternately opposing a resisting and non-resisting surface, the whole force or impulse may operate in a direct manner upon the resisting side of the sail or vane, in proportion to its extent; and that when the non-resisting side is returning against these powers, the mill being so contrived that there is very little resistance, however large the surface. These improvements, when applied to horizontal wind-mills, the power of them, even with the same quantity of sail, or acting surface, may too be increased or diminished at pleasure, which is a circumstance of very great utility and convenience in many cases.

WIND-Pump, that sort of pump which is so contrived and formed as to be driven by the wind. These kinds of pumps are very useful for draining and lifting water in many cases, as where the depth of it is too great to admit of cutting drains, or the superstrata too loose for forming them, and when the height to which the water is to be raised is great. See **SPRING-Draining** and **SURFACE-Draining**.

WIND-Row, in *Agriculture*, a term signifying the green parts or borders of a field, dug up, in order to carry the earth on other land to mend it; so called because it is laid in rows, and exposed to the wind. It also signifies a row of peats set up to dry for fuel. Likewise a row of hay exposed to the wind and sun to get dry. And also of turfs or sward cut up in paring and burning.

The peats are set up in these rows in an open manner, to the height of two or three feet or more, that the wind may pass between and dry them. The rows of hay of this kind are either single or double, the former for that which is in the more grassy state, and the latter for that which has been more made; and the work is performed by different persons raking

raking the spread hay in opposite directions towards themselves, and by such means forming a row between them of double the extent of that of the single wind-row. See *HAY-Making*.

The turf or sods for burning are set up in these rows, in leaning directions against each other, so as to let the wind readily pass among and dry them in a quick manner for burning.

Whins are sometimes, too, formed into wind-rows for being burnt for the ashes. See *WHIN-Asbes*.

WIND-Sail, or *VENTILATOR*, in a *Ship*, is made of canvas, and used for circulating fresh air between the decks, and is in the form of a cylinder, or an obtuse-ending cone, and is adapted to the size of the ship. Four breadths of canvas are sewed together, and the outer selvages are joined with an inch seam, leaving one cloth four feet short of the top. A three-inch tabling goes round the top and bottom. It is kept distended by circular hoops, made of ash, sewed to the inside, one at top, and one at every interval of six feet. The upper part, or top, is covered with canvas, and a small rope sewed round the edge; into which are spliced, at the quarters, the ends of two pieces of rope, that are sewed up to the middle, and an eye formed by seizing the bights. The length of a wind-sail is taken nine feet above the deck, to three or four feet below the lower hatchway; the quantity of canvas is obtained by multiplying the number of cloths by the length.

These, of which there are generally three or four in our capital ships of war, have the advantage of taking little room, of requiring no labour in working, and of a simple contrivance, so that they can fail in no hands. But their powers are said to be small in comparison with those of Dr. Hales's ventilators: they cannot be put up in hard gales of wind, and are of no efficacy in dead calms, when a refreshment of air is most wanted. See *VENTILATOR*.

WIND-Seed, in *Botany*. See *ARCTOTIS*.

WIND-Shock, a name given by our farmers to a distemper to which fruit-trees, and sometimes timber-trees, are subject.

It is a sort of bruise and shiver throughout the whole substance of the tree; but the bark being often not affected by it, it is not seen on the outside, while the inside is twisted round and greatly injured.

It is by some supposed to be occasioned by high winds; but others attribute it to lightning. Those trees are most usually affected by it, whose boughs grow more out on one side than on the other.

The best way of preventing this in valuable trees, is to take care in the plantation that they are sheltered well, and to cut them frequently in a regular manner while young.

The winds not only twist trees in this manner, but they often throw them wholly down: in this case, the common method is to cut up the tree for firing, or other uses; but if it be a tree that is worth preserving, and it be not broken but only torn up by the roots, it may be proper to raise it again by the following method:—Let a hole be dug deep enough to receive its roots, in the place where they before were; let the straggling roots be cut off, and some of the branches, and part of the head of the tree; then let it be raised, and when the turn-up roots are replaced in the earth in their natural situation, let them be well covered, and the hole filled up with rammed earth; the tree will, in this case, grow as well, and perhaps better, than before. If nature be left to herself, and the tree be not very large, the pulling off the roots will raise it. Mortimer's Husbandry, vol. ii. p. 79.

WIND-Tackle Blocks, in a *Ship*. See *WINDING-Tackle*.

WIND-Taught, in *Sea Language*, denotes the same as stiff

in the wind. Too much rigging, high masts, or any thing catching or holding wind aloft, is said to hold a ship wind-taught; by which they mean, that she stoops too much in her sailing in a stiff gale of wind.

Again, when a ship rides in a main stress of wind and weather, they strike down her top-masts, and bring her yards down, which else would hold too much wind, or be too much distended and wind-taught.

WIND-Thrush, in *Ornithology*, a name given by some to the red-wing, and supposed to be given from their generally first appearing with us in windy seasons; but it appears more probably to be derived from the German name *wint-trossel*, or vine-thrush, from its doing great mischief there in the vineyards, by eating and destroying the grapes. Ray.

WIND-Tumours. See *TUMOUR*.

WIND-Ward, in *Sea Language*, denotes any thing towards that point from whence the wind blows, in respect of a ship.

WIND-Ward, Sailing to. See *SAILING*.

WIND-Ward Tide denotes a tide which runs against the wind.

WIND, in *Geography*, a river of America, which runs into the Connecticut at Windsor.

WIND Gap, a pass in the Blue Mountains of Pennsylvania.

WINDAGE of a Gun, is the difference between the diameter of the bore and the diameter of the ball.

The windage is not the same in England as it is abroad. With us, if the diameter of the shot is divided into twenty equal parts, then the diameter of the bore is twenty-one of these parts. The French suppose the diameter of the shot divided into twenty-six parts, and the diameter of the bore to be twenty-seven. Mr. Muller observes, that the less windage there is, the truer the shot will go, and having less room to bounce from one side to another, the gun will not be spoiled so soon. Accordingly, he divides the diameter of the shot into twenty-four equal parts, and makes the bore twenty-five, which is a medium between the English and French method. Artillery, p. 84.

Dr. Hutton observes, that if the windage be one-twentieth of the calibre, which is the usual size, no less than one-third or one-fourth of the powder escapes, and is lost. As the balls are often smaller than the regulated size, it frequently happens, that half the powder is lost by unnecessary windage.

Dr. Hutton also recommends the diminishing of the windage. See *GUNNERY*.

WINDALA, in *Geography*, a town of Sweden, in East Bothnia; 65 miles E. of Wala.

WINDALL, a town of the state of Vermont; 22 miles S.S.W. of Windsor.

WINDASS, *WANDASS*, or *WANLASS*, an ancient term in hunting. Thus, to drive the windass signifies the chasing of a deer to a stand, where one is ready with a bow, gun, or to shoot. This is one of the customary services of fiefs.

“—Omnes illi qui tenerunt in bondagii tenura, solebant vocari custumarii: & quotiescunque dominus ad venandum venerit, illi custumarii solebant fugare windassum, ad stabulum, in venatione ferarum bestiarum secundum quantitatem tenuræ suæ.” MS. de Consuetud. Manerii de Sutton Colfield, an. 3 Ed. II.

WINDAU, in *Geography*, a sea-port town of the duchy of Courland, near the mouth of the Wera, on the Baltic. It was the capital of a palatinate, and has a castle, once the residence of the Livonian knights; the states of Courland likewise held their assemblies here, which made it populous; but it is now much decayed, and chiefly supported by ship-building, and exporting pitch, tar, wax, &c.; 8 miles N.N.E. of Piltyn. N. lat. 57° 10'. E. long. 21° 32'.

WINDAU.

WINDAU. See WETA.

WINDECK, a town of France, in the department of the Scheldt; 9 miles S.S.E. of Ghent.—Also, a town of the duchy of Berg; 21 miles E. of Bonn.

WINDECKEN, a town of Germany, in the county of Hanau Munzenberg; 4 miles N. of Hanau.

WINDELSBACH, a town of the margravate of Anspach; 22 miles N.W. of Anspach.

WINDER, in *Agriculture*, a term used provincially to signify to clean corn with a fan-machine. See FAN-Machine.

WINDER-Meb, in *Ornithology*, the name of a bird of the larus, or gull-kind, the *larus cinerarius* of Linnæus, moderately large, and described by Aldrovandus under the name of *larus major*.

Its head is remarkably large and thick, and is of a mottled colour of white and grey; its breast and belly are also variegated with the same colours, but they are somewhat paler; its beak is thick and strong, of a yellow colour, and very sharp, and the opening of its mouth very wide; its wings are variegated with white, grey, and chestnut colour, and both these and the tail have much black in them; the feet are webbed and yellow, the claws are sharp, and the hinder toe larger than in most birds of this kind. Ray's *Zoology*, p. 267.

WINDERS of Wool. See WOOL-Winders.

WINDHAM, or WYMONDHAM, in *Geography*, a town of England, in the county of Norfolk, with a weekly market on Friday. The chief trade of the place is making wooden ware. In 1549, William Kett, one of the Norfolk insurgents, was hanged on the steeple of the church; 9 miles W.S.W. of Norwich. N. lat. $52^{\circ} 34'$. E. long. $1^{\circ} 7'$.

WINDHAM, a large post-township of Greene county, in New York, comprising all that part of the county on the S. and W. of the summit of the Catsbergs or Catskill mountains; bounded N. by Durham, Cairo and Catskill, E. by the northern angle of Ulster county, S. by Ulster and a part of Delaware counties, and W. by Delaware county. It has a post-office, and is about 24 miles in length, its medial breadth being about 12 miles.

It is mountainous, with much good pasture-lands that yield excellent dairy. It is watered by the Schoharie creek, which has several mill-seats and small branches. Along these streams are some alluvial lands, which are rich and fertile. The view from the Catsbergs, over which is a road, is very grand and interesting. The W. part of Windham is about 35 miles W. from Catskill, its principal market. The population consists of 3965 persons, and the senatorial electors are 267.

WINDHAM, a town of the state of Connecticut, on the Thames. It is the chief town of a county, to which it gives name. The county contains 28,611 inhabitants, and the town 2416; 63 miles S.W. of Boston. N. lat. $41^{\circ} 38'$. W. long. $72^{\circ} 11'$.—Also, a town of the state of Vermont, in the county of Windham, with 782 inhabitants; 20 miles E. of Bennington.—Also, a county in the S.E. part of the state of Vermont, bordering on the Massachusetts. It contains 26,760 inhabitants.—Also, a post-town of New Hampshire, in Rockingham county, with 743 inhabitants; 40 miles S.W. of Portsmouth.

WINDING, twisting from an even surface, or not a direct plane.

WINDING a Call, in *Sea Language*, denotes the act of blowing or piping upon a boatwain's whistle, so as to communicate the necessary orders of hoisting, heaving, belaying, slackening, &c. See CALL.

WINDING-Engine, in *Mining*, a machine employed to wind or draw up corves or buckets out of a deep pit or shaft. There are several different machines employed for this purpose, and each has a different name.

The most simple winding-machine is a roller placed horizontally over the pit, to wind up the rope, by which the bucket is suspended; the roller is turned round by a handle at each end. This simple machine, which is called a wind-lafs, wind-up, or roller, is commonly used for well-digging, and formerly was the common machine for mines; but for mining on the present system more powerful machinery is required. In Derbyshire it is called a slowse, and the construction is very minutely directed in the ancient mining-laws of the district, called 'The King's Field.' A small model or effigy of a slowse, constructed according to law, and fixed up "in sight of all men," is still the sign of legal possession of a lead-mine, and one of these must be constantly maintained at every thirty-nine yards in length of the vein of ore; for by those laws no man may work more than thirty-nine yards, and it is supposed that each one of these is a separate working and drawing up of the ore from the mine.

With this simple machine a man can work continually to draw up a weight of 3750 pounds, at the rate of one foot *per* minute, or any smaller weight with a proportionably quicker motion. This is a fair average of the strength of man, which has been determined by a number of experiments, as shewn in our article WATER. The radius of a winch or handle should not be above fourteen inches, which describes a circle of $7\frac{1}{2}$ feet circumference; a man can turn this round twenty times *per* minute with convenience, and the motion of his hands will therefore be $146\frac{1}{2}$ feet *per* minute, at which rate a man can exert a force of $25\frac{1}{2}$ pounds according to our standard. To apply a man's force to the greatest advantage, we must not depart much from these proportions; but the load which is drawn up at one time may be varied according to the diameter of the roller or barrel on which the rope winds: for instance, if this barrel is seven inches diameter, it will draw up the weight only one-fourth as fast as the man moves the handle; and in consequence the weight may be $4 \times 25\frac{1}{2} = 102$ pounds, and this he will be able to wind up at the rate of thirty-seven feet *per* minute. It is best to employ two men, and make the two handles at right angles to each other; the roller may then be 14 inches diameter, and they can draw up the 102 pounds at the rate of 74 feet *per* minute. The roller should have two ropes wrapped upon it in opposite directions, and a bucket being suspended from each, one bucket will be drawn up as the other is let down, and no time will be lost.

The next machine is the horse-gin: it has a large drum or barrel to wind up the rope; the barrel is mounted on a vertical axis, which is provided with one or more long levers, to the extreme ends of which a horse is harnessed, and by walking round in a circle, the barrel is turned round, and the rope which descends into the pit or shaft, is wound up by wrapping round the barrel. The gin is placed at a convenient distance from the mouth of the pit, and the rope is conducted over a pulley at the top of the pit, to change the direction from horizontal to vertical. The horse-gin usually has two ropes wrapping round the barrel in opposite directions, and one winds up as the other unwinds. The two buckets or corves which are suspended in the pit at the same time, go up and down alternately, one full and the other empty, and the weight of the empty corve, which is descending, tends in some measure to balance that which is coming up full.

The barrel must be turned in a contrary direction every time a basket is drawn up, and for this purpose the horse is turned

turned round every time, so as to draw the barrel round in one direction the first time, and in a reverse direction the next time. The horse turns at the same time that the baskets are unhooked and changed at the top and bottom of the pit, and very little time is lost. A boy is required to lead and direct the horse. In some large horse-machines wheel-work is introduced, to communicate the motion of the vertical axis of the horse-levers to the barrel on which the rope winds; and this work may be so contrived as to reverse the motion of the barrel at pleasure, although the horses always walk in the same direction.

In very deep pits an inconvenience is experienced from the weight of the great length of rope which must be employed; for the whole weight of this rope is added to the weight of the loaded corve when it is at the bottom of the pit; and at the same time, the other corve being at the top of the pit, there is no length of rope on that side to counterbalance. As the corve is drawn up from the bottom, the other descends into the pit; this shortens the length of the ascending rope, and increases the descending rope, so that by the time that the corve is half drawn up, the other is let half down, and the weight of the rope is equally divided, so as to be in balance; but after this, the descending rope becomes the longest, and its weight tends to weigh up the loaded corve, and in very deep pits, the weight of the rope exceeds that of the corve so as to draw it up: hence, there is a great inequality in the force required to turn the machine. To remedy this, the barrel is often made of a conical shape, being smallest in the middle, and larger towards the upper and lower ends; the ends of the two ropes are made fast to it in the middle, or at the smallest part, and therefore the horse has greater power when the corve is to be drawn from the bottom, and all the length of rope is added to its weight, because the rope winds on a smaller radius; but as the rope coils on the barrel, it winds on a larger part of the cone, and the power or leverage diminishes; therefore, the horse will draw up the corve with a rapidity which increases in proportion to the diminution of the load, by the shortening of the rope.

A very convenient mode of constructing a double conical barrel is to fix two circular wheels upon the axis, one for the top of the barrel, and the other for the bottom of the same. Two old cart-wheels are frequently employed for this purpose. The barrel on which the rope is wound is formed by a number of straight pieces of wood, which are fixed to the rims of the wheel, and extend from the upper to the lower one. These pieces are not fixed in a direction parallel to the vertical axis of the barrel, but are fixed crosswise in an oblique direction, and thus form a barrel, which is small in the middle, and larger at the ends. When a cylindrical drum is fixed upon the main shaft to wind up the rope, if the pit is deep, a counterbalance to the weight of the rope must be applied to a smaller conical drum fixed on the vertical axis above the great drum. The circumference of the conical barrel is grooved with a spiral groove, like the fusee of a watch; upon this fusee a rope is applied, which descends into a small pit made on purpose, and has a counter-weight at the end of it: this balances the unequal weight of the great rope, if the rapidity of the cone is properly proportioned. This answers very well for small depths; but for a deep pit, the fusee must be placed on a separate barrel. This barrel may be placed horizontally over the pit in which the balance-weight descends, and must have a wheel upon it to communicate by a rope with a wheel fixed upon the vertical axis of the gin; by this means, the same motion is communicated to a spiral, as if it was placed immediately on the vertical axis.

A perfect equal motion is not necessary for horse-work, and if it is not so much in extremes as to strain the horse in one part of his journey, whilst he has nothing to do in another, he will work very well. Gentle ascents and descents in a road are found as advantageous to the action of horses as a road upon a perfect flat. The following is the construction recommended by Mr. Smeaton for a two-horse gin for a lead-mine:—The horse-track 36 feet diameter, and two horses are employed at once; the diameter of the drum 14 feet; the weight to be drawn at once $5\frac{3}{4}$ cwt. or 644 lbs. exclusive of the bucket, because there are two, and the one serves as a balance for the other; depth of the pit 45 fathom, or 270 feet; the girth of the rope $6\frac{1}{2}$ inches. The counterbalance for the unequal weight of the great rope is constructed as follows:—Above the drum or rope-wheel, a smaller one, or balance-drum of one-fourth the diameter of the great drum, or 3 feet 6 inches, must be firmly fixed to the upright axis; also a little shaft or pit must be sunk at a convenient distance from the machine: if this is opposite the great pit, it will require less bracing to keep the fixed parts of the framing at their proper distances. A hole must be made in the circumference of the small wheel, or balance-drum, through which the end of a rope is passed, and secured by a knot. This rope, which is for the counter-weight, is to pass over a pulley of 3 feet or more diameter, such as is used to direct the great ropes down the main shaft; but it must be strongly and substantially fixed, because there will be a greater strain upon it. Over this pulley the balance-rope goes down into a little pit sunk for the purpose, and a balance-weight is hung to it, which must be double the weight of 45 fathom of the main pit-rope, and it will act as a counter-weight to the great pit-rope. The counter-weight must not, however, go down so as to touch the bottom of the little pit; and it must be so regulated as to be at the lowest point when the two buckets are at their meetings, half way down the main pit. Hence, whichever way the main drum turns round, the counter-weight will be drawn up, and will arrive at the top when either of the buckets arrive there: by this means, whatever be the weight of the rope, though it exceeds the weight of matter in the bucket, yet the horse will always have something to draw; whereas in the old horse-gins made at Newcastle, they had no other method than turning the horses at the point of equilibrium; and after that letting them draw the backward way, which obliged them also to walk backwards, till the bucket arrived at the top.

As a $6\frac{1}{2}$ -inch rope is far more than equivalent to the weight required to be drawn, the same sort of rope will do for the counter-weight also; but as there will be a great deal of chafing at the hole where it is fixed to the little drum-wheel, in consequence of its bending alternately one way and then the other, it will be proper to fortify it there with the white leather made of horses' skins, and the hole itself should be rounded off on each side, so as to make the rope bend easily.

In the sinking of the little shaft, if there is any particular advantage or obstacle, the depth may be greater or less than a quarter part of the main shaft; but then the size of the little drum and counter-weight must be proportioned accordingly. If practicable, the pit had better be deeper; and if it was half the depth, then the little drum might be half the diameter of the large one, and the counter-weight would be no more than the weight of the rope in the great pit. On account of the expence of the balance-pit, the double conical drum, which requires no counter-weight, is much preferable to any machine with a counter-weight.

In our article WATER we have given the experiments on the strength of horses; from which it appears that a proper load

WINDING-MACHINE.

load for a horse to work eight hours in a day is 22,000 lbs. avoirdupois, to be raised one foot in a minute, or any smaller weight to be drawn quicker in proportion; hence the weight of 644 lbs. may be drawn by two horses at the rate of 71 feet *per* minute, or the whole depth of 45 fathoms in $3\frac{3}{4}$ minutes. The horses will then walk in their circle rather more than three miles *per* hour; but $2\frac{1}{2}$ miles is the best pace. Horses are frequently loaded much more than this, and indeed one strong horse may work this machine; but as he could only work a short time each day, it is better to employ two.

When mines were sunk to very great depths, the drawing of the ore by horse-gins became too expensive, particularly for coal-mines, and more effective winding-machines were introduced. The water-gin was the first of these. The most simple of these is called a whimsey, and consists of a bucket, which is let down full of water, and by its descending force, draws up a loaded basket or corve from the bottom of the pit. (See WHIMSEY.) This machine requires a very considerable fall of water, and it can rarely be less than one-fourth or sixth of the whole depth from which the coal or ore is to be drawn.

In cases where the fall is smaller, an over-shot water-wheel is employed; and in order to make the wheel turn at pleasure either way round, so as to wind up or let down, the wheel is made double; that is, with two rows of buckets, one row adapted to receive the water from a spout, which will cause it to turn round in one direction, and the other row of buckets is supplied with water from a different spout, and will turn the wheel in the opposite direction. Each spout is provided with valves to stop the stream at pleasure, and when one is open the other must be shut, and thus the wheel may be made to turn either way round. This is a very old invention, and is fully described by Agricola in his *De Re Metallica*, 1621. It was at one time in very common use in the collieries, and they raised up the supply of water for it by a pump applied to the beam of the great steam-engine, or sometimes by an engine on purpose.

Mr. Smeaton made a machine, in 1774, for drawing coals at Griff, in Warwickshire, by a water-wheel, in which the motion of the wheel is always continued in the same direction; and by a change in the communication of the wheel-work, the barrel is made either to draw up or to let down.

In 1777 Mr. Smeaton made a larger machine for Long Benton colliery, at Newcastle, which is worked by the water raised by a steam-engine on Newcomen's principle. The water-wheel and machinery are represented in *Plate Winding-Engine*, in several different elevations. X is the over-shot water-wheel, which is 30 feet in diameter: it is mounted on a cast-iron axis, which is clearly represented in the drawing. The water is delivered upon the wheel by a spout from a trough or cistern, which is supplied by the pump of the steam-engine. This trough is supported on tall piers of masonry, one of which is shewn in the sketch. Upon the axis of the water-wheel are fixed two cog-wheels, U V, of 88 cogs each, and the cogs are turned towards each other; W is a trundle, which is situated between the two wheels, and is turned round by either of them, according as it is placed; but it is smaller in diameter than the space between the two wheels, so that it cannot engage with both wheels at the same time. The trundle is fixed at the extremity of a long shaft, as shewn in the plan, *fig. 1*; and the opposite end of this shaft is connected with the barrel on which the ropes are wound: this barrel is composed of two cones, joined together at their bases. The ropes from the barrel are conducted over pulleys at the top of the pit, as

shewn in the elevation, *fig. 2*, and descend into the same. The baskets, or corves, in which the coals are brought up, are hooked to the ends of the two ropes; so that by the motion of the water-wheel one basket is drawn up whilst another is let down.

To regulate the motion of the machine, two brakes or gripes are applied: one encompasses the great cog-wheel U, which is fixed on the axis of the water-wheel, in the same manner as the brake of a wind-mill; and in like manner, the fixed circle or brake is provided with a lever, as shewn in *fig. 4*, by means of which the brake can be drawn tight round the wheel, and will then cause such a friction as to stop the water-wheel and all the machine.

The other brake-wheel DC (*fig. 1*.) is fixed near the end of the long axis, and has clogs or pieces of wood applied at the top. This piece of wood is supported by a lever AB, as shewn in *fig. 2*, A being the centre; and to the other end, B, a box E is suspended, and contains as much weight as will press the clog upon the wheel, with the force necessary to retain the corve from descending when it is full loaded. To enable the man at the mouth of the pit to lower down the corve, a cord is fastened to the lever AB, and is conducted over the pulleys, *g k* and *l*, to the mouth of the pit, where it hangs down in a knot, which the man can always reach, and by pulling it, he raises up the lever, and releases the wheel from the clog. To prevent accidents, if the clog and lever A should fail to stop the machine, another clog and lever FG are applied beneath the wheel; this lever is drawn upwards by a cord and a block of pulleys O, which are attached to the lower part of the weight for the upper lever. This cord is conducted to the pit's mouth, and hangs down, so that the man can always reach it, and by pulling this, he compresses both the upper and lower clogs upon the wheel at the same time, which will be certain to stop it even if it be in a rapid motion; but he only resorts to this lower clog on occasion, as the curb-rein is used for a horse; the weight of the upper lever, like a horse's bridle, being a sufficient check for common use.

To make the machine wind either up or down, the trundle W must be changed from one of the wheels, U or V, to the opposite one, and this will cause the barrel to turn in an opposite direction. The pivot of the trundle W is supported by the long upright beam shewn in *fig. 3*, which is moveable on a centre at the lower end, so that by inclining it to the right or left, the trundle may be engaged with either of the wheels U or V. The requisite motion is given to the upright beam by two tackles of pulleys applied to the upper end of the beam, as shewn in *fig. 3*.

The ropes of both these tackles are fastened together, and hang down in a loop in reach of a boy, who can pull it either way, and make the trundle engage with either wheel, so as to wind up or let down the corves at pleasure. This boy is always stationed in a small room immediately over the wheels UV, so as to have the brake-lever, as well as the upright lever, always at his command; likewise the shuttle of the water-wheel, which is fixed, as is shewn in *fig. 3*. A lever is made to communicate with it, and from the opposite end of the lever a rod descends into the room, so that the boy, by pulling it, can open or shut the shuttle at pleasure. This he must do whenever the corve comes up, or rather before; and notice of the proper time is given by a large knot in the main rope. The water being then shut off, the wheel will continue to turn by its momentum until the corve comes fully up, but by that time will have diminished its velocity, so that the application of the brake will stop it without any strain: the man at the mouth of

the pit also applies the brake on the wheel C D. Immediately the motion ceases, the boy pulls the tackle, which disengages the trundle W from the wheel, but without engaging it with the opposite one, and in consequence the barrel is detached from the water-wheel. A man now seizes the corve with a long hook, like a shepherd's crook, and draws it aside; then another man releases the clog or brake on the wheel C D, and the wheel and the corve immediately descend upon the ground at the side of the pit. The pulley over the pit is raised up to a considerable height, because the machine cannot be stopped exactly at the precise spot; but if the corve should be drawn up a few feet higher than necessary, no harm can ensue as soon as the full corve is landed and exchanged for an empty one; and the same is done at the bottom of the pit. The boy throws the trundle in gear with the opposite wheel, then draws the shuttle to let the water flow upon the wheel, and the wheel resumes its motion.

For the facility of stopping the machine at the proper moment, Mr. Smeaton applied a piece of machinery, which he called a count-wheel. This received its motion from a pinion of 15 teeth, fixed upon the extremity of the pivot of the lantern W; the pinion gave motion to a small cog-wheel of 60 teeth, situated between the two great cog-wheels U V, being fixed at one end of an horizontal spindle; and at the opposite end of it was a pinion of eight teeth, which gave motion to the count-wheel. This wheel had 80 teeth, and was fixed in a vertical position. It had affixed to its plane two projecting pieces of iron, which operated upon a lever that was connected with the lever which lets down or draws up the shuttle to regulate the flow of water upon the wheel. These projections were so fixed to the wheel as to be capable of regulation in such manner, that when the machine had worked long enough to have brought up the corve to the top of the pit, the projection of the count-wheel would seize the lever, and let fall the shuttle so as to stop the water-wheel at the proper moment, without any attention on the part of the boy. This could be easily regulated by the position of the projection on the count-wheel, and when once adjusted always operated correctly; for as the count-wheel turned only once for forty turns of the barrel, the machine would therefore draw up a corve from the bottom of the pit before the count-wheel made a complete turn.

As the two corves in the pit ascend and descend mutually, they must pass each other at half the breadth of the pit; and it sometimes happens that they strike together, and overset the coals. The best remedy for this is to divide the pit in two, or make two separate pits, and the barrel may be situated between the two. As it is frequently impracticable to do so, a smaller projection was applied in Mr. Smeaton's machine upon the count-wheel, which acted in the middle of the course upon the lever, and raised it up so as to diminish the opening of the water-shuttle, and make the machine move slowly at the moment when the corves met and passed each other: this prevented accidents.

The principal dimensions of this machine were as follow:—The cylinder of the steam-engine 26 inches diameter, and 5 feet 8 inches the length of stroke. It made 14 strokes *per* minute. It was on the principle of Newcomen, *i. e.* atmospheric, with injection into the cylinder. The pump was 18½ inch bore, and 5 feet 8 inches stroke: it raised the water 33 feet high. This water, being conveyed in a trough to the machine, was delivered upon the water-wheel, which was 30 feet diameter, with 72 buckets; its cast-iron axis was 7 inches diameter; the great cog-wheels 12 feet diameter, with 88 cogs; the trundle 20 cogs, so that the barrel turned 4.4 times for once of the water-

wheel. The barrel was 5 feet 3 inches diameter in the middle, and 2 feet 11½ inches diameter at the ends; the whole length being 10½ feet. Upon the circumference of the barrel a spiral line is traced, and a groove sunk, which receives half of the rope, to prevent the rope from slipping on the barrel.

The depth of the pit was 165 yards; and it was found, on a long course of experiments, that the total consumption of coals was one corve of coals to draw up 82½ corves from that depth. The machine would draw 18 score of corves, each containing 20 pecks and weighing 5½ cwt., every 12 hours.

The more modern winding-engines by steam are upon a much more simple construction. The power of the steam-engine is applied at once to the barrel which winds up the rope, with only one pair of cog-wheels; *viz.* a large wheel fixed on the axis of the barrel, and a smaller one on the axis of the fly-wheel of the steam-engine. These engines are frequently made on Newcomen's principle, as the consumption of coals is a small object, but Mr. Watt's engines are more manageable. As the steam-engine with a crank will turn either way, according as it is let in motion, it is very well adapted for winding-machines; the boys who manage them are very dexterous in stopping and turning them the contrary way. See *STEAM-Engine*.

There are many ingenious contrivances for facilitating the landing of the corves when they come up to the pit's mouth. The best is a platform, which runs upon wheels, and can be pushed over the pit's mouth, when the corve is drawn up, by means of a light carriage with one horse, which is backed on the platform beneath the corve, and pushes the platform over the pit by the same motion. The corve is lowered down upon the carriage, and then the horse draws the corve away; the same motion withdraws the platform from the pit's mouth, ready to let down an empty corve and draw up another full one.

In many modern pits, conductors are fixed in the pit. These are perpendicular rods, and the baskets have projecting parts which embrace the conductors, and guide the corve regularly up or down the pit.

In many collieries flat ropes are used. These are composed of four small ropes placed flat, side by side, and sewed together by a packthread, which pierces all the four ropes. When these flat ropes are used, a barrel or drum of small size is used, and the coils of the rope wind one upon the other, so as to form a spiral, and increases the diameter of the effective barrel as the rope winds up, so as to balance the weight of the rope. This was invented by Mr. John Curr, of Sheffield, who has several patents for machinery for manufacturing such flat ropes, as they are extensively used in Yorkshire.

In others, iron chains are used instead of ropes, and are found to answer extremely well.

WINDING of Cotton. See *COTTON Manufacture*.

WINDING of Silk. See *Manufacture of SILK*.

WINDING-Screw Cheese-Press, in *Rural Economy*, a contrivance of this sort, in which the weight is laid, in the Gloucestershire Report on Agriculture, to be capable of being gradually let down on the vats. It is thus described:—A strong platform, or fill, is raised on four legs, about a foot from the floor; near the edge is made a channel all round, to carry off the whey as it is expressed, by a lip, into the pan or receiver. Two strong side-posts are mortised into the fill, reaching about six feet high; across which, about four feet high, is firmly fastened a strong bar, with an aperture in the centre large enough to let in the screw with ease. This screw is fixed, at the lower part, into a heavy cubical stone

of two feet dimensions, or nearly: the upper part of the screw, having passed the perforation in the cross-bar, enters a nut or female screw, large in the middle, but worked off at the two ends fine enough to be grasped by the hand: by turning this nut, the weight is raised or let down on the cheefe-vats underneath.

Where stones of the required weight and dimensions are not to be had, a wooden frame of the same size is used, which is filled with sand, pebbles, or rubble-stones.

The screw part of this press has, in many dairies, been lately superseded by the adoption of an apparatus less simple in its construction, though more easily worked. In which, on the right side of the press, a third upright is raised from the floor, and connected by two cross-bars, about a foot long, with the upright post parallel with it. About four feet high, a cylinder of wood, from five to six inches diameter, is inserted, passing quite through the additional upright, but kept to its place by a shoulder. To the end are fixed four spokes, or levers, or an iron handle, to which manual power is applied. A strong rope is fastened to and coiled round the cylinder, which passing over a pulley let lengthways into the upper bar, proceeds horizontally to another pulley, fixed directly over the centre of the weight, and by an iron hook attached to it. Very moderate strength will raise the weight, which in this construction slides with grooves fitted to the side-posts. The mechanical powers are varied in some presses by the use of a wheel of a foot or eighteen inches diameter, instead of the pulley; but the effect is similar. In either way of working the weight, there is a superiority over the old press, and little difference in the expence.

WINDING Stairs. See **STAIR.**

WINDING of Wool, in *Rural Economy*, the practice of putting it up into fleeces. There is some nicety required in this operation; all the loose ragged parts are to be turned inwards, so as to form a neat solid sort of fleece, and all the dirty parts removed. The work is done on a large table or bench for the purpose. In some cases of expert winders, four hundred fleeces can be wound in the course of the day.

WINDISCH FEISTRITZ, in *Geography*, a town of the duchy of Stiria, on the river Plufcka; 40 miles S. of Gratz. N. lat. 46° 30'. E. long. 15° 28'.

WINDISCH Gratz, a town of the duchy of Stiria; 18 miles N.N.W. of Cilley. N. lat. 16° 35'. E. long. 15°.

WINDISCH Landberg, a town of the duchy of Stiria; 12 miles E. of Cilley.

WINDISCH Mark, a part of Carniola, bordering on Hungary and Croatia.

WINDISCH Matray, a town of the archbishopric of Salzburg; 54 miles S.S.W. of Salzburg. N. lat. 46° 55'. E. long. 12° 36'.

WINDISH, a village of Switzerland, near Konigsfelden, at the conflux of the Aar and the Reufs, in the canton of Berne, in which are found the ruins of the ancient city of Vinodonissa, a fortress mentioned by Tacitus, which the Romans made a place of arms to stop the irruption of the Germans, and is said to have been the see of a bishop. It was destroyed in the 7th century; 3 miles W. of Baden.

WINDISHGARTEN, a town of Austria; 16 miles S.W. of Bavarian Waidhoven.

WINDLASS, or **WINDLACE,** a machine used for raising heavy weights, as guns, stones, anchors, &c.

It is very simple, consisting only of an axis, or roller, supported horizontally at the two ends by two pieces of wood and a pulley. The two pieces of wood meet at top; being placed diagonally, so as to prop each other. The axis, or roller, goes through the two pieces, and turns

in them. The pulley is fastened at top, where the pieces join.

Lastly, there are two staves, or handspikes, which go through the roller, by which it is turned; and the rope, which comes over the pulley, is wound off and on the same.

WINDLASS, an horizontal machine, composed of timber, &c. and most used in merchant-ships for heaving up their anchors in lieu of a capstan. The body of the windlass is octagonal, and is tapered from the middle to the ends by given dimensions. It is sawn from oak-timber of the best quality, and the length between the cheeks is in one piece. But when fitted with an iron axle or spindle in the middle, it must be in two pieces. The ends without the cheeks are fitted with iron spindles, and have a hoop driven over their ends. The spindles must be very accurately let into the ends and middle of the body, that the axis of each may exactly agree in a right line. A bolt is driven through the body of the windlass and each end of the spindles. On each end of the body is let on and securely bolted an iron pall-hoop, with teeth or notches at every two or three inches. The palls, which are iron, are fixed against the aft-sides of the pall-bits, and fall into the teeth or notches of the pall-hoop, so as to prevent it turning backwards when charged by the effort of the cable, &c. Holes or mortises are cut through, along the middle of the windlass on each square, to admit the handspikes, and each square of the body is covered with elm or fir facings between the cheeks, on the working side in particular. It is suspended by its axles or spindles in brass rhodings, or gudgeons, which are let in and bolted into a frame of oak-timber called the cheeks, which are let down through the deck, and bolted to the pall-bits.

There are other methods of fitting windlasses, but this is recommended as the best.

WINDLASS-Cheeks, pieces of oak or elm fastened to the sides of small vessels, and by which the ends of their windlasses are suspended.

WINDLE, in *Geography*, a township of England, in Lancashire; 10 miles N.E. of Liverpool.

WINDLESTRAW, in *Agriculture*, a term applied to the naked stems of the crested dog's-tail, and other natural grasses.

It is observed in the third volume of the Transactions of the Highland Society of Scotland, that the common *poa* there sometimes goes by the name of windlestraw-grass. See **GRASS,** and **POA.**

WINDMANNIA, in *Botany.* See **WEINMANNIA.**

WINDO, in *Geography*, a sea-port town of Sweden, in the province of Smaland; 85 miles N. of Calmar.

WINDORS, a town of the bishopric of Passau; 10 miles W. of Passau.

WINDOT CREEK, a river of America, which runs into the Ohio, N. lat. 37° 59'. W. long. 86° 48'.

WINDOW, *q. d.* **WIND-DOOR,** an aperture, or open place, in the side of a house, to let in the air and light.

Before glass windows came into use, (for the antiquity and first introduction of which, see **GLASS,**) the window casements were commonly made of a transparent stone, called *specularis lapis*, and thence called *specularia*; and before the *specularia*, veils were the only defence they had against the weather. Pitisc. Lex. Antiq. in voc. *Specularia*.

We have various kinds and forms of windows; as glass-windows, wire-windows, horn-windows, &c. Arched windows, circular windows, elliptical windows, square and flat windows, round windows, oval windows, Gothic windows, regular windows, rustic windows; to which add skylights.

The chief rules with regard to windows are, 1. That they be as few in number, and as moderate in dimensions, as may consist with other respects; inasmuch as all openings are weakenings.

2. That they be placed at a convenient distance from the angles, or corners of the building; because those parts ought not to be opened and enfeebled, whose office is to support and fasten all the rest of the building.

3. That care be taken the windows be all equal one with another, in their rank and order; so that those on the right-hand may answer to those on the left, and those above be right over those below; for this situation of windows will not only be handsome and uniform, but also, the void being upon the void, and the full upon the full, it will be a strengthening to the whole fabric.

As to their dimensions, care is to be used to give them neither more nor less light than is needful; therefore regard is to be had to the bigness of the rooms which are to receive the light. It is evident, that a great room needs more light, and, consequently, a greater window, than a little room; and *c contra*.

The apertures of windows, in middle-sized houses, may be four and a half or five feet between the jambs; and in the greater buildings, six and a half or seven feet; and their height may be double their length at the least. But in high rooms, or larger buildings, their height may be a third, a fourth, or half their breadth, more than double the length.

Such are the proportions for windows of the first story; and, according to these, must those in the upper story be for breadth; but, as to height, they must diminish; the second story may be one-third part lower than the first; and the third story, one-fourth part lower than the second.

WINDOWS, *Architrave*. See ARCHITRAVE.

WINDOWS, *Dormer*, or *Lutherns*. See LUTHERNS, &c.

WINDOWS, *Scenography of*. See SCENOGRAPHY.

WINDOWS, *Transom*. See TRANNSOM.

WINDOW and *House Tax*, is one of the assessed taxes transferred to the commissioners for the affairs of taxes. The duties charged annually with respect to the windows or lights in every dwelling-house, (for which, see TAX,) are subject to the following regulations.

All skylights, and all windows or lights, however constructed, in staircases, garrets, cellars, passages, and all other parts of dwelling-houses, to what use or purpose soever applied, and whether such windows or lights shall be in the exterior or interior parts of such dwelling-houses, to be charged to the said duties.

Every window or light in any kitchen, cellar, scullery, buttery, pantry, larder, washhouse, laundry, bakehouse, brewhouse, and lodging-room, belonging to or occupied with any dwelling-house, whether the same shall be within or contiguous to or disjoined from the body of such dwelling-house, shall be charged to the said duties.

The said duties to be charged yearly upon the occupier or occupiers of the houses, cottages, or tenements, in respect whereof the said duties shall be charged, and to be in force for one whole year, from the 5th day of April in the year in which the same shall be charged, to be levied on them, or on their respective executors or administrators, except as hereinafter provided.

Where any change in the occupation of any house, cottage, or tenement, shall take place after the assessment shall be made, then the said duties shall be levied upon and paid by the occupier, landlord, or owner, for the time being, or on both or all of them, according to their times or possession thereof, without any new assessment, notwithstanding

such change in the occupation for the year that such house shall have been assessed: provided, that where a tenant shall quit the same, on the determination of the lease or demise after an assessment made, and shall have given notice thereof to the assessor, the duty shall be discharged by the commissioners for this act for the remainder of that year, in case it shall appear to them at the end of such year, that such house, &c. shall have continued wholly unoccupied during the remainder of such year.

Where any dwelling-house is or shall be let in different apartments, tenements, lodgings, or landings, and shall be inhabited by two or more persons or families, the same shall nevertheless be charged as if inhabited by one person or family only; and the landlord or owner shall be deemed and taken to be the occupier, and shall be charged with the said duties: provided, that where the landlord shall not reside within the limits of the collector, or the same shall remain unpaid by him for twenty days after the same is due, the duties so charged may be levied on the occupier or occupiers respectively, and such payment shall be deducted and allowed out of the next payment on account of rent.

Every house, of which the keeping is left to the charge of any person or servant, shall be subject to the like duties as if it were inhabited by the owner or by a tenant; and, if such person or servant shall not pay rates to the church and poor, the said duties shall be paid by the respective owners or tenants of the said house.

Every distinct chamber or apartment in any of the inns of court, or of chancery, or in any college or hall in either of the universities of Oxford or Cambridge, or any public hospital, being severally occupied, shall be subject to the same duties as if an entire house, which shall be paid by the respective occupiers; provided, that every such chamber or apartment, which shall not contain more than seven windows or lights, shall be charged at the rate of 3s. 6d. for every such window or light.

All dwelling-rooms in any hall or office whatever, belonging to any person, or to any body politic or corporate, or to any company, lawfully charged with the payment of any other taxes or parish-rates, shall be subject to those hereby payable, and be respectively charged as dwelling-houses; and the person, &c. to whom the same shall belong shall be charged as the occupier or occupiers thereof.

When a partition or division between two or more windows or lights, fixed in one frame, is of the breadth or space of twelve inches, the window or light on each side of such partition or division shall be charged as a distinct window or light.

Every window extending so far as to give light into more rooms, landings, or stories than one, shall be reckoned and charged as so many separate windows as there are rooms, landings, or stories enlightened thereby.

Every window or light, including the frame, partitions, and divisions thereof, which by due admeasurement of the whole space on the aperture of the wall of the house or building, on the outside of such window or light, shall exceed in height twelve feet, or in breadth four feet nine inches, not being less than three feet six inches in height, shall be reckoned and charged as two windows or lights, except such windows or lights as shall have been made of greater dimensions at any time prior to April 5, 1785; except also the windows or lights in such parts of dwelling-houses as are used for shops, workshops, and warehouses, and except the windows or lights in the public room of any house licensed to sell wine, ale, or other liquors by retail, which shall be used for the entertainment of guests; and the windows or lights in farm-houses especially exempted from the duties

duties in the schedule marked (B.), or in any dwelling-house not chargeable to the duties mentioned in the said schedule.

Where any dwelling-house shall be divided into different tenements, being distinct properties, every such tenement shall be subject to the same duties as if the same were an entire house, which duties shall be paid by the respective occupiers; provided, that every such tenement, which shall not contain more than seven windows or lights, shall be charged at the rate of 3s. 6d. for every such window or light; and every such tenement in Scotland, which shall not contain more than seven windows or lights, shall be charged at the rate of 3s. for every such window or light.

The cases in which windows are exempted are the following.

1. Any house belonging to his majesty, or any of the royal family, and every public office, for which the duties heretofore payable have been paid by his majesty or out of the public revenue.

2. Any hospital, charity-school, or house provided for the reception and relief of poor persons, except such apartments therein as are or may be occupied by the officers or servants thereof, which shall severally be assessed, and be subject to the said duties as entire dwelling-houses.

3. The windows in any room of a dwelling-house, licensed according to law as a chapel for the purposes of divine worship, and used for no other purpose whatsoever.

Provided that every such hospital, charity-school, house for the reception and relief of poor persons, or room licensed as a chapel as aforesaid, shall be brought into charge by the assessor or assessors, or in their default, by the surveyor or inspector, and shall be stated on the certificate of assessments as such; and on due proof of the fact before the commissioners for executing the said act to discharge such hospital, &c. from the said duties, or such part thereof as is hereby intended to be exempted, in like manner as they are authorized to discharge the assessment on poor persons by this act, but not otherwise.

4. The windows or lights, in any dairy or cheese-room belonging to and occupied with any dwelling-house, chargeable with the said duties, although the same shall be part thereof, which shall be used by the occupiers for the purpose of keeping butter or cheese, being their own produce, for sale or private use; provided, that the windows or lights in such dairies or cheese-rooms shall be made with splines or wooden laths, or iron bars, or wires, and wholly without glass, and that the occupiers of the dwelling-houses to which such dairies and cheese-rooms belong shall cause to be painted on the outer door thereof, or on the outside of the windows thereof, or one of them, in large Roman letters, the words, "dairy, or cheese-room," as the case may require, and shall keep such words so painted distinctly legible, during all such time as such exemption shall be claimed; and provided, that such dairies or cheese-rooms shall not be ever used to dwell or to sleep in by any person, but shall be wholly kept for the several purposes hereinbefore mentioned; and provided also, that an assessment of all such windows or lights shall be duly made, and the fact be truly returned in the manner directed by this act, in other cases of exemption from the said duties, so that the number of windows so to be exempted may be ascertained, and the exemption be allowed by the commissioners for executing this act.

The provisions that respect the exemptions of windows from assessment by 43 Geo. III. c. 161. are as follow.

Windows are to be stopped up with stone or brick, or the same kind of materials as the outside of the house; allow-

ance being made for those in the roof made of the same materials with the outside of the roof, or stopped up before the commencement of this act; or windows are not to be made, reftored, or stopped up without six days' previous notice given to the surveyors, under a penalty of 10l.: and surveyors are to charge windows newly made or reftored, and omitted in the assessment; and the penalty on stopping up windows to elude payment is a charge on the occupier of the tenement, at the rate of double the sum by which the assessment shall be augmented, by reason of such certificate, subject to appeal, provided it be proved to the satisfaction of the commissioners for executing this act, that the same windows or lights were respectively stopped up according to the directions of this act, previous to the commencement of the year on which the said assessment shall or ought to have been made.

The duty on dwelling-houses (for which, see TAX) comprehends every coach-house, stable, brewhouse, washhouse, laundry, woodhouse, bakehouse, dairy, and all other offices, and all yards, courts, and curtilages, and gardens, and pleasure-grounds, belonging to and occupied with any dwelling-house, within the limits of one acre.

All shops and warehouses which are attached to the dwelling-house, or have any communication therewith, shall, in charging the said duties, be valued together with the dwelling-house and the household and other offices aforesaid thereunto belonging, (except such warehouses and buildings upon or near adjoining to wharfs which are occupied by persons who carry on the business of wharfingers, and who have dwelling-houses upon the said wharfs for the residence of themselves or servants employed upon the said wharfs.)

And also except such warehouses as are distinct and separate buildings, and not parts or parcels of such dwelling-houses, or the shops attached thereto, but employed solely for the purpose of lodging goods, wares, and merchandize, or for carrying on some manufacture (notwithstanding the same may adjoin to or have communication with the dwelling-house or shop.)

Every chamber or apartment in any of the inns of court, or of chancery, or in any college or hall in any of the universities of Great Britain, being severally occupied, shall be charged thereto as an entire house, and on the respective occupiers thereof.

Every hall or office whatever belonging to any person or to any body politic or corporate, or to any company lawfully charged with the payment of any other taxes or parish-rates, shall be subject to the duties as inhabited houses; and the person, &c. to whom the same shall belong shall be charged as occupier.

Where any house shall be let in different stories, tenements, lodgings, or landings, and shall be inhabited by two or more persons or families, the same shall nevertheless be charged to the said duties as if inhabited by one person or family only, and the landlord or owner shall be deemed the occupier, and shall be charged to the said duties: provided, that where the landlord shall not reside within the limits of the collector, or the same shall remain unpaid by such landlord for the space of twenty days after the same is due, the duties so charged may be levied on the occupier or occupiers respectively; and such payment shall be deducted and allowed out of the next payment on account of rent.

No dwelling-house, or other such premises as aforesaid, shall be estimated or rated at any less annual value than the rent or value at which the same premises stand charged in the last rate made on or before the time of making the assessment

assessment for the relief of the poor in the same parish or place, under certain specified restrictions with regard to the poor rate.

Where any dwelling-house shall be divided into different tenements being distinct properties, every such tenement shall be subject to the same duties as an entire house, which duty shall be paid by the occupiers respectively.

The cases of exemption are the following.

1. Any house belonging to his majesty, or any of the royal family, and every public office for which the duties heretofore payable have been paid by his majesty, or out of the public revenue.

2. Every dwelling-house, being a farm-house occupied by a tenant, and *bonâ fide* used for the purposes of husbandry only.

3. Every dwelling-house, being a farm-house occupied by the owner thereof, and *bonâ fide* used for the purposes of husbandry only, which, together with the household and other offices aforesaid, shall be valued under this act at 10*l. per annum*, or any less sum.

4. Any hospital, charity-school, or house provided for the reception or relief of poor persons.

5. Every house whereof the keeping is committed to the care of any person or servant, who doth not pay rates to the church and poor, and who resides therein for the purpose only of taking care thereof: provided, that an assessment shall be duly made in every such case, and the fact be truly returned in the manner directed by this act in other cases of exemption from the said duties, and the exemption be allowed by the commissioners for executing this act.

Any person inhabiting a dwelling-house, containing not more than six windows in the whole, shall be exempted from the duties in schedule (A.), in case such person shall be on the books of such parish or place as receiving parochial relief; and shall not be assessed, or liable to be assessed to any of the duties contained in schedules (B.), (C.), (D.), or (E.); which several exemptions shall be proved or claimed in the manner hereinafter mentioned.

And, in order to relieve such persons who may be charged to the several duties set forth in the schedules (A.) and (B.), or either of them, it is enacted, that where any such house, cottage, or tenement, as is described in the preceding clause, shall be brought into charge, and the occupier thereof shall be entitled to the said exemption by reason of poverty, in every such case, the assessors shall, on the certificate of assessment, set opposite the sum charged on the occupier thereof, the fact of his or her being poor, and shall return the same, together with the assessment and a certificate, as hereinafter mentioned, to the commissioners for executing this act in the district where such assessment shall be made; who, before allowing any such assessment, or making any order thereupon, shall examine the assessors, who shall respectively attend them for that purpose, at such time as they shall appoint, touching the return so made; and if the said commissioners shall, from such examination, and from the certificate hereinafter mentioned, be satisfied that any such occupier is entitled to such exemption, they may, after such proof, strike out the charge, leaving his name, and the number of windows and rent of such house in the assessment, and every such occupier shall be exempted accordingly; which exemption shall, in the like cases, extend to, and shall be allowed on all assessments on such poor persons, of the duties payable at the time of passing this act, which shall have been, or shall be made, at any time after the commencement of the present year.

But before any such exemption or abatement shall be allowed, the assessors shall produce to the commissioners a

certificate under the hands of five or more substantial householders of such parish or place, in vestry assembled, of whom the resident minister shall be one; but in case there shall be no such minister resident therein, then at least two or more churchwardens and overseers of the poor of such parish or place shall concur with such householders in such certificate, certifying thereby, that they have carefully examined the assessment of the said duties, and the allegations therein made by the assessors, touching such persons who shall be therein stated to be poor, and that in their judgment and belief the persons therein certified to be poor are entitled to be exempted by reason of their poverty, and are wholly unable to pay the duties assessed upon them; provided, that if in any parish or place there shall not be five substantial householders, then such certificate may be made by the substantial householders there residing; or if there shall be no churchwardens or overseers, then the same may be granted by the resident minister, or by any two churchwardens or overseers of any adjoining parish or place, who can certify the truth of such allegations, concurring therein with the substantial householders residing in the parish or place where such assessment shall be made.

And where the occupier of any house, cottage, or tenement, containing more than the number of windows or lights before specified, shall be brought into charge, and the occupier thereof shall, at the commencement of the year for which such assessment is made, be poor and indigent, or shall become so during that year, in every such case, such occupier may give notice thereof in writing, stating the causes to the assessor, or to the surveyor of the district in which such house is situate, annexing thereto a certificate, under the hands of such persons as aforesaid, certifying that, in their judgment and belief, such person is justly entitled to relief on account of poverty for the causes mentioned in such notice; and every assessor shall deliver the notices by him received to such surveyor: and if such surveyor shall be satisfied of the truth thereof, after due examination of the facts and circumstances, and that such person is unable to pay the duties charged on him or her, and has no probable means of bettering his or her condition within that year, he is hereby required to certify the same to the commissioners; and if such surveyor shall not be satisfied, then, on notice thereof to such occupier, he may appeal from such charge to the commissioners, giving ten days' previous notice thereof to the said surveyor.

And in every case where the surveyor shall certify to the said commissioners that he is satisfied of the truth of the claim made by any such occupier, and that he is, and will be unable to pay the duties charged on him or her within that year; or if, upon appeal, it shall appear to the satisfaction of the major part of the said commissioners present, on the oath of such appellant, or by other lawful evidence on oath produced by such appellant, that he or she is entitled to maintain such appeal, and wholly unable to pay the duties charged on him or her, the said commissioners may give such relief, either by striking off the whole of the duty so charged, or diminishing the same, as to them shall seem meet and necessary; and which appeals, for the causes in this clause mentioned, may be heard and determined, either on the days mentioned in this act for hearing appeals in other cases, or at the end of the year, or any days to be appointed by the respective commissioners for executing this act; which exemption shall, in the like cases, extend to, and shall be allowed on all assessments on such poor persons of the duties payable at the time of passing this act, which shall have been or shall be made at any time after the commencement of the present year.

Unoccupied houses are to be inferted in the affeffment, and the affeffors, or the furveyors and infpectors, are to certify when they become occupied; and the perfon occupying fhall give notice to the affeffor, furveyor, or infpector, within twenty days after occupation, under a penalty of 5*l.*, and be liable to be charged for the ref of the preceding quarter; and houfes becoming unoccupied after affeffment are to be charged for the whole year, unlefs notice is given. Notices are alfo to be given by occupiers of houfes or managers of hofpitals, charity-fchools, poor-houfes, or licenfed chapels, entitled to exemptions; and the exemptions are to be allowed by the commiffioners after examination. Burn's Juftice, vol. v. See TAX and COMMUTATION.

WINDOW, in *Anatomy*, &c. See FENESTRA.

WINDRUSH, in *Geography*, a river of England, in the county of Oxford, which runs into the Thames, 5 miles S.S.W. of Witney.

WINDSBACH, a town and citadel of Germany, in the principality of Anfpach; 10 miles S.E. of Anfpach. N. lat. 49° 13'. E. long. 10° 46'.

WINDSHEIM, a town of Bavaria. The inhabitants are chiefly Lutherans. This town was imperial till 1802, when it was given to the elector of Bavaria; 28 miles S.W. of Wurzburg. N. lat. 49° 34'. E. long. 10° 26'.

WINDSOR, commonly called NEW WINDSOR, to diftinguifh it from a parifh named Old Windfor, a market and borough town of Berkfhire, England, is eminent in the hiftoric annals of the kingdom, on account of containing one of the palaces of the fovereigns, and from the many diftinguifhed events which are identified with the place. Some of our moft eminent military and chivalrous fovereigns have made the caftle, or palace of Windfor, their chief refidence, and confequently the fcene of various celebrated feftivities, tournaments, and national affemblies. In the annals of the caftle, this is fully verified. When the Domefday-book was compiled, the caftle, which had been then lately built by William the Conqueror, was within the manor, and it is probable within the parifh of Clewer, of which Windfor was formerly a chapelry: it afterwards became the feat of an extenfive honor.

We are told by the Saxon Chronicle, that William the Conqueror kept his Whitfuntide at Windfor in 1071; and that a fynod was held there in 1072, wherein the province of York was made fubject to Canterbury. It is probable, that William Rufus kept his Whitfuntide at Windfor in 1095, his Christmas in 1096, and his Eafter in 1097: but in all probability all thefe feftivals were held at the palace at Old Windfor. Windfor-caftle feems to have been intended by William the Conqueror more for a military poft, for which by its fituation it was well adapted, than for the refidence of himfelf and his fucceffors.

Several monarchs kept their Christmas and other feftivals at Windfor; on fome of which occafions there were tournaments and other chivalrous fêtes performed. After the contentions between Stephen and Maud, Windfor-caftle, as the fecond fortrefs of the kingdom, was committed to the cuftody of Richard de Lacy.

It appears that a new barbican, or out-work, was built to the caftle by king Henry III. In 1263, during the wars between that monarch and his barons, prince Edward garrifoned Windfor-caftle with foreigners, who nearly deftroyed the town, and did much injury to the furrrounding country. The fame year it was given up to the barons, and the king made an order that Eleanor, wife of prince Edward, with her daughter and all her houfehold, fhould, without delay, retire from the caftle.

A great tournament was held in Windfor-park on the 9th of July, in the fixth of king Edward I. That monarch and his fucceffor, king Edward II., refided frequently at Windfor, where feveral of their children were born.

John, king of France, and his fon Philip, were prifoners in Windfor-caftle. David, king of Scotland, is alfo faid to have been prifoner there at the fame time.

All hiftorians agree, that Windfor-caftle owes its magnificent fabric to the affection which king Edward III. bore to the place of his nativity. Walfingham relates, that in 1334, he built a chamber, which he called the round table, 200 feet in diameter: this, by other accounts, appears to have been only a temporary ftructure. Holinghed fays, that in 1359, "the king fet workmen in hand, to take down much old buildings belonging to the caftle of Windfor, and caufed divers other fair and fumptuous works to be fet up in and about the fame caftle, fo that almoft all the mafons and carpenters, that were of any account within the land, were fet for, and employed on the fame works." But it appears that various commiffions for appointing furveyors and imprefing workmen had been iffued fome years before; and that in 1356, William of Wykeham, then one of the king's chaplains, was made clerk of the works with ample powers, and a fee of one fhilling a day whilft at Windfor, and two fhillings when he went elfewhere upon bufinefs: his clerk had a falary of three fhillings a week. In 1359, the architect's powers were further enlarged, and he was appointed keeper of the manors of Old and New Windfor. The next year 360 workmen were imprefed to be employed on the buildings at the king's wages, fome of whom having clandestinely left Windfor, and engaged in other employments for greater wages, writs were iffued to prevent perfons employing them, on pain of forfeiting all their goods and chattels, and to commit fuch of the workmen as fhould be apprehended to Newgate. The plague having carried off a great number of the king's workmen in 1362, new writs were iffued to the fheriffs of feveral counties to imprefs 302 mafons and diggers of ftone to be employed in the king's works. The counties of York, Salop, and Devon, were to furnifh fixty men each. Glaziers were imprefed in the year 1363; very few commiffions were iffued after the year 1369, and none after 1373, fo that it may be prefumed that this noble work was then completed; comprifing the king's palace, the great hall of St. George, the lodgings on the eaft and fouth fides of the upper ward, the round tower, the chapel of St. George, the canon's houfes in the lower ward, and the whole circumference of the walls, with the towers and gates.

The appeal of high treafon, brought by the duke of Lancafter againft Thomas Mowbray, duke of Norfolk, in 1398, was heard by king Richard II., on a fcaffold erected within the caftle at Windfor, when, it being found impoffible to reconcile the opponents, a day of combat was appointed to take place at Coventry. The caftle continued to be the occafional refidence of our monarchs, who from time to time made various alterations in the buildings, particularly king Henry VII. Windfor-caftle was garrifoned by the parliament, foon after the breaking out of the civil war between Charles and his fubjects; and colonel Venn, who was afterwards one of the king's judges, was appointed the governor. Prince Rupert made an unfucceffful attack upon it in the autumn of 1642. The caftle continued under the jurifdiction of parliament during the war, and in the year 1648 became the prifon of its unfortunate monarch. Judge Jenkyns was alfo a prifoner here for feveral years; whence he was removed to Wallingford, in 1656.

Upon the Reftoration, king Charles II. finding the build-
ings

ings of the castle much dilapidated by plunder and neglect, caused it to be thoroughly repaired and richly furnished. During the greater part of his reign, he made Windsor his summer residence. King James II. in 1687 received the pope's nuncio at Windsor-castle. Queen Anne, when princess of Denmark, lived in a small house adjoining the little park, and was very partial to Windsor.

During the reign of his present majesty, Windsor-castle has undergone considerable improvements, under the direction of the late James Wyatt, esq. surveyor-general of his majesty's works.

The castle consists of two courts, between which is the keep, or round tower. The upper court contains on the north side the state apartments, chapel, and the hall of St. George. The east and south sides have been lately fitted up for the residence of their majesties and the royal family. Our limits will not allow us to enter into a detail of the magnificent rooms which constitute the state apartments, or of dwelling on the valuable collection of pictures therein contained.

St. George's hall, on the north side of the upper ward, was built by king Edward III., as a refectory for the knights companions of the garter: it is a noble room 108 feet in length. The ceiling and walls are painted by Verrio; the subjects are the triumphs of the warlike founder, and his brave son, Edward the Black Prince.

In the area of the upper court is a bronze statue of king Charles II. on horseback, executed by Stada at the expence of the munificent Tobias Rustat.

On the north side of the castle is the terrace made by queen Elizabeth, which was extended by king Charles II. along the east and south sides: its whole length is 1870 feet, and it may be regarded as the noblest walk of the kind in Europe, as well as the most interesting in situation.

The chapel of St. George is situated on the north side of the lower court of the castle. King Henry I. built a chapel at Windsor, dedicated to St. Edward the Confessor, and placed in it eighty canons, who were maintained out of the king's exchequer. This chapel appears to have been rebuilt, or considerably enlarged and decorated, by king Henry III.: that monarch, in the year 1243, issued a commission to Walter de Gray, archbishop of York, to expedite the works at the king's chapel at Windsor, directing that the workmen should proceed as well in winter as in summer, till the whole was completed; that a lofty wooden roof, like the roof of the new work at Lichfield, should be made to appear like stone-work, with good ceiling and painting: that the chapel should be covered with lead, and four gilded images be put up in it, where the king had before directed images of the same kind to be placed; and that a stone turret should be made in front of the chapel of sufficient size to hold three or four bells. Some remains of Henry III.'s buildings, as may be presumed by the style of the arches and architectural decorations, may be seen on the south side of the dean's cloisters, and at the east end of the chapel behind the altar.

King Edward III., who had been baptized at Windsor, rebuilt St. Edward's chapel there, and dedicated the new structure to the Virgin Mary and St. George. In the year 1349, he augmented the number of canons to twenty-three, besides a warden; and appointed 24 poor knights, for all of whom he built habitations, and granted land for their support. In 1351, the bishop of Winchester made considerable alterations in the college; and Henry IV. changed the title of warden to that of dean.

The present splendid and truly interesting chapel of St. George may be regarded as the most perfect and most

beautiful pile of ecclesiastical architecture in the kingdom. It was commenced by king Edward IV. and committed to the superintendance of Richard Beauchamp, bishop of Salisbury. The work was not completed till the reign of king Henry VIII.: the beautiful roof of the choir was put up in the year 1508. Sir Reginald Bray, prime minister to king Henry VII., and one of the knights companions of the order of the garter, who died in 1502, succeeded bishop Beauchamp in the superintendance of this great work, and was a liberal contributor to the building of the choir and other parts of the fabric: his cognizance is frequently repeated on the roof of the choir, as are the royal arms and those of several noble families with the order of the garter. The rood loft and lanthorn were erected in 1516; the present organ-gallery and screen at the end of the choir are of Coade's artificial stone. The stalls of the knights companions, which are very richly carved in wood, exhibit the names and arms of the several illustrious and noble persons by whom they have been respectively filled. The altar-piece, which represents the Last Supper, is by Mr. West, from whose designs the east window, representing the Resurrection of our Saviour, was executed in painted glass by Jarvis and Forest, and put up in 1788: the expence of the latter was about 4000*l*. Another window by the same artists display the angels appearing to our Saviour. Most of these improvements, as well as several others in the chapel and castle, have been executed under the patronage, and partly at the expence, of his present majesty. Beneath the choir repose the remains of Henry VIII., his queen, lady Seymour, and king Charles I. Henry VI. was also interred in this chapel; also his rival and successor, Edward VI.

At the east end of the south aisle is the Lincoln chapel, which contains the monument of Edward, earl of Lincoln, lord high admiral of England for thirty years, who died in 1584. Sir Henry Clinton, bart., a descendant of the earl of Lincoln, was buried in this chapel in 1795. In the same aisle is an elegant chantry chapel, built by John Oxenbridge, canon of Windsor. Farther west is a chapel built by Dr. Oliver King, bishop of Bath and Wells, who died in 1492.

In the middle of the south aisle is a spacious chapel, founded by sir Reginald Bray, who died in 1502, and is here interred: his arms and crest appear in several parts of the chapel, particularly in the beautiful screen which separates it from the aisle.

At the west end of the south aisle is the Beaufort chapel, in which is an altar-tomb with the effigies of the founder, Charles Somerfet, earl of Worcester, who died in 1526, and his lady; and a splendid monument, supported by Corinthian pillars, to the memory of Henry, the first duke of Beaufort, who died in 1699.

Near the south door of the choir is interred Charles, duke of Suffolk, a favourite minister and brother-in-law of king Henry VIII., who died in 1545.

On the west side of the choir-door in the north aisle is a chapel built by Elizabeth, wife of William, lord Hastings, who is buried here.

At the east end of the chapel is a distinct though attached building, called the tomb-house, which was commenced by Henry VII. and intended for his burial place. It was granted by Henry VIII. to cardinal Wolsey, who began a sumptuous monument for himself within its walls. This was destroyed in the civil wars. James II. fitted up the building as a Roman Catholic chapel; and publicly attended the celebration of mass. After that monarch's decease the chapel was deserted; but in 1800 his present majesty gave orders

orders for it to be repaired, beautified, and appropriated for the interment of his family. The princess Mary and the princess Charlotte of Wales have been committed to its vault. On the north and east sides of the chapel are houses and lodgings for the dean and canons. The south and west sides of the lower ward are occupied by houses appropriated to the poor knights.

Between the two wards or courts of the castle is the keep, or round tower, for the residence of the governor of the castle. It consists of a lofty, artificial, conical mount, surrounded by a moat, and surmounted by a strong fortified tower, which is approached by a flight of 100 steps. The circumference of the whole castle is 4180 feet; its length from east to west 1480 feet; and the area, exclusive of terrace walks, is about twelve acres.

On the south side of the castle is a modern mansion, called the Queen's-lodge, where the royal family resided for several years; but it is now unoccupied. About half a mile S.E. of the castle is Frogmore, a modern seat belonging to the queen. It is principally noted for its beautiful garden.

To the south and west of the town is *Windfor Forest*, which formerly was computed to measure 120 miles in circuit. At present it is about 56 miles. A part of this, called the great park, consists of 3800 acres. The little park, on the north and east sides of the castle, contains about 500 acres.

Windfor is a large irregular town, disposed on the sides of a hill, and at its base, on the southern banks of the Thames. In 1276 it was declared a free borough by king Edward I., who granted to the burghesses a mercatorial guild, and various privileges and exemptions. He constituted it the county-town. King Edward IV. incorporated the burghesses by the name of mayor, bailiffs, and burghesses. By the last charter of king Charles II., the corporate body is made to consist of twenty-eight or thirty members. A weekly market is held by royal grant, as well as three annual fairs. Near the centre of the town is a guildhall or town-house, which was built in 1666.

This borough sent two members to parliament in the reign of Edward I.; but omitted making any returns from 1340 to 1446. The right of election has frequently been contested, but was finally settled to be vested in all the inhabitant householders not receiving alms. Windfor has continued to increase in population for the last 300 years. In 1555, there appears to have been 1000 persons; in 1801, they amounted to 3461; and in 1811 to 6155, who occupied 1051 houses. The parish-church is a spacious building, and part of it ancient, though it was formerly only a chapel subordinate to the church of Clewer. In it are several old monuments. On the west side of the town are extensive barracks, and an hospital for sick soldiers.

WINDSOR, *Old*, a village about two miles S.E. of New Windfor, was a place of some consequence at the time of the Domeſday-survey, as by that record it is stated to contain 95 houses, which paid gabel tax to the crown. Some of the Saxon kings had a palace here, and Edward the Confessor sometimes kept his court at this place. After William the Conqueror had erected a castle at New Windfor, the old palace and the surrounding houses were gradually deserted. A great part of Windfor-park is within the parish of Old Windfor, and includes three lodges: 1. The great lodge built in the reign of Charles I. and occupied by the illustrious William, duke of Cumberland; 2. The little lodge or dairy, occupied by the deputy ranger; and 3. The nanor lodge near Virginia water. Beaumont lodge, the seat of lord viscount Ashbrooke, was originally built by lord Weymouth, who died in 1705. There are other fa-

mily mansions and villas in this parish; one of which was lately fitted up and occasionally occupied by the princess Elizabeth, now princess Homberg.—The Magna Britannia, by S. Lysons and the Rev. D. Lysons, Berkshire, 4to. 1806. The Beauties of England, &c. vol. i. by J. Britton, F.S.A. and E. W. Brayley, 8vo. 1801. The History of Windfor and its Neighbourhood, by J. Hake-will, Architect, 4to. 1813. This elegant volume contains accounts and views of several places in the vicinity of Windfor. The History of the Royal Residences, 4to. 1817, by J. Pyne, a very handsome and interesting work, contains several views of the state apartments in Windfor-castle. The Architectural Antiquities of Great Britain, 4 vols. 4to. by J. Britton, contains several views, and a full history and description of St. George's chapel.

WINDSOR, a large township in the south-east corner of Broome county, New York, erected in 1807 from the east part of Chenango; situated 15 miles E. of Chenango; bounded north by Chenango county, east by Delaware county, south by the state of Pennsylvania, and west by Chenango. Its extent is nearly 15 miles square, and it has two post-offices. It is traversed by the Susquehanna river. In 1810 it had eleven saw-mills, seven grain-mills, a fulling-mill, and carding-machine, eight school-houses, one house of worship, a population of 1960 souls, 138 electors, and nearly 300 families.

WINDSOR, a town of Nova Scotia; 25 miles N.W. of Halifax.—Also, a town of the state of Vermont, capital of a county of the same name, which contains 34,877 inhabitants; the town contains 2757 inhabitants; 92 miles N.W. of Boston. N. lat. 43° 33'. W. long. 72° 22'.—Also, a town of the state of Connecticut, on the west side of the Connecticut river, in the county of Hartford, with 2868 inhabitants; 3 miles N. of Hartford.—Also, a town of Massachusetts, in the county of Berkshire, with 1108 inhabitants; 136 miles W. of Boston.—Also, a township of Pennsylvania, in Berks county, with 1358 inhabitants; 70 miles W. of Philadelphia.—Also, a township of Pennsylvania, in York county, with 1739 inhabitants.—Also, a town of New Hampshire, in the county of Hillsborough, with 238 inhabitants.—Also, a town of North Carolina; 23 miles S.W. of Edenton.—Also, a township of Lower Canada, on the St. Francis.

WINDSOR, *East*, a town of New Jersey, in Middlesex county, with 1747 inhabitants.—Also, a town of the United States of America, in Connecticut, on the east side of the Connecticut, opposite Windfor, with 3081 inhabitants.

WINDSOR, *West*, a town of New Jersey, in Middlesex county, with 1714 inhabitants.

WINDSOR, *New*, a post-township of Orange county, New York, on the west bank of the Hudson; 100 miles S. of Albany; bounded north by Montgomery and Newburgh, east by the Hudson, south by Cornwall and Blooming-grove, west by Montgomery and Walkkill. Its medial extent east and west is eight miles, and north near four, giving an area of about 30 square miles. Its population in 1810 consisted of 2331 persons, and its senatorial electors were 147. It has two post-offices, viz. the village of New Windfor, pleasantly situated on the west bank of the Hudson, and having considerable trade; and Little Britain, said to be discontinued in 1813. This township has several mill-streams, and the land is occupied chiefly by farmers, who enjoy much of the independence resulting from prosperous industry. The whole is well watered by springs and brooks.

WINDSOR *Forest*. See WINDSOR.

WINDSOR *River*, a river of the state of Connecticut, which runs into the Connecticut, 4 miles N. of Hartford.

WINDSOR *Bean*, in *Agriculture and Gardening*. See BEAN, and VICIA.

WINDTBERG, in *Geography*, a town of the duchy of Holstein; 4 miles S.S.E. of Meldorp.

WINDTHAAG, or WINDTHAG, a town of Austria; 3 miles E. of Bavarian Waidhoven.

WINDWARD PASSAGE, a name given to a course from the south-east angle of the island of Jamaica, in the West Indies, and extending from 160 leagues to the north side of Crooked island, in the Bahamas. Ships have often sailed through this channel, from the north part of it to the island of Cuba, or the gulf of Mexico, notwithstanding the common opinion, on account of the current which is against it, that they keep the Bahama shore on board, and that they meet with the wind in summer for the most part of the channel easterly, which, with a counter current on shore, pushes them easily through it.

WINDWARD *Islands*, in opposition to Leeward. These islands in the West Indies extend from Martinico to Tobago. See WEST INDIES.

WINDWARD *Point*, a cape on the north-east coast of the island of St. Christopher. N. lat. 17° 23'. W. long. 62° 22'.

WINDY TUMOURS. See TUMOUR.

WINE, the fermented juice of the grape. The name is also applied to the fermented juice of other subacid fruits.

It is impossible to fix the era when mankind first discovered fermented liquors. Some historians have ascribed the discovery to Noah, others to Saturn, others to Bacchus, &c. In short, almost every country in which the vine is indigenous has boasted of some individual or native deity, to whom the honour has been attributed; and if we reflect upon the simplicity of the processes essentially necessary to be had recourse to in making wine, it will appear exceedingly probable that the discovery was not made by one person or country exclusively, but by different individuals and nations at very different periods. A poet has elegantly represented wine as a recompence given by the deity for the miseries brought upon mankind by the general deluge:

“ ——— Deus nobis felicia vini
Dona dedit, tristes hominum quo munere fovit,
Reliquias; mundi solatus vite ruinam.”
Prædium Rusticum.

Different kinds of wine were known at a very early period; and as civilization and luxury advanced, the number was greatly extended. Hence the cultivation of the vine became an object of importance, and many new varieties were produced, which, favoured by soil and situation, rendered particular places more famous than others. Thus the ancient Romans not only possessed a great variety of native wines, but, in the days of their greatest splendour, those also of distant and still more favoured climes, as the *Vinum Chium*, *Lesbium*, *Leucadium*, *Rhodium*, &c. &c. See Pliny, xiv. 6.

Little is known respecting the modes of manufacturing some of the most celebrated of the ancient wines. The general processes, however, did not perhaps differ much from those at present in use. The fruit was collected, bruised by the feet, and subjected to pressure, as now practised. The juice that first flowed spontaneously was called *πρωτοπον* by the Greeks, and by the Romans *vinum primarium*; such as was obtained by pressure was denominated *δευτεριον*, or *vinum secundarium*, and considered as inferior.

Both Greeks and Romans appear to have frequently concentrated their wines, either by spontaneous evaporation, or by boiling. For the former purpose, the wine was sometimes introduced into bladders or large jars, and exposed in

the chimney to the heat of the fire, or in the upper parts of the house to the heat of the sun. Sometimes the fruit was converted into raisins by drying, and the wine prepared from such fruit was denominated *passum*. At other times the *must* was reduced by boiling to one-half. This formed the *vinum defrutum*: occasionally even to one-third, when it was termed *Sapa*. (See Pliny, xiv. 9.) By one or perhaps more of these methods, the wines were reduced to the state of syrup, or in some instances even to dryness, and were capable of being preserved for a very long time. Thus Aristotle states, that the Arcadian wines required to be diluted with water before they were drunk, as indeed was the case with most of the ancient wines; and Pliny speaks of wines as thick as honey, which it was necessary to dissolve in warm water, and filter through linen, before they were used. This was the case with the wine of Cæcuba, according to Martial:

“Turbida folicito transmittere Cæcuba facco.”

Pliny mentions Staphylus as the first who mixed wine with water; but Athenæus gives the credit of it to Amphitryon, king of Athens. On this occasion a fable was invented, that Bacchus, having been struck by a thunderbolt, and being all inflamed, was presently cast into the nymphs' bath, to be extinguished.

These remarks, however, are applied by the above authors chiefly to very old wines. Thus the wine compared by Pliny to honey had been made two hundred years before, in the time of consul Opimius: indeed wines of a hundred years old, and upwards, seem not to have been uncommon among the luxurious citizens of ancient Rome. (See Hor. od. iii. 14. 18. Juvenal, v. 34.) And similar allusions will be found in various other authors. Seven years was the shortest period, according to Aristotle and Galen, for keeping a wine before it was fit for drinking.

Among the Romans, the age of wines was, as it were, the criterion of their goodness. Horace, in his odes, which one may call *Bacchic songs*, boasts of his drinking Falernian wine, born, as it were, with him, or which reckoned its age from the same consuls.

The age of wine has been reckoned by leaves: thus they say, wine of two, four, or six leaves, to signify a wine that was two, four, or six years old; taking each new leaf put forth by the vine, since the wine was made, for a year. The moderns keep no wine to such an age as that mentioned by Pliny. Where they are kept the longest, as in Italy and Germany, there are scarce any to be found of above fifteen leaves. In France, the wines that keep best, as those of Dijon, Nantz, and Orleans, are reckoned superannuated at five or six years old.

Wine kept in a cool vault, and well secured from the external air, will preserve its texture entire in all the constituent parts, and sufficiently strong for many years, as appears not only from old wines, but other foreign fermented liquors, particularly those of China, prepared from a decoction of rice, which being well closed down in the vessel, and buried deep under ground, will continue, for a long series of years, rich, generous, and good, as the histories of that country universally agree in assuring us.

Sir Edward Barry, in his Observations, historical, critical, and medical, on the Wines of the Ancients, suggests, that our best modern wines, especially those of a delicate texture and flavour, may be more effectually preserved in earthen vessels of a larger size than our bottles, well glazed externally and internally: that dry sand is preferable for covering the bottles in the bins to saw-dust; and that a small

WINE.

small anti-cellar, built before all large cellars, would be a considerable defence and improvement.

The ancients were fond of giving their wines an artificial flavour, and for this purpose they introduced pitch, turpentine, and different herbs into the *must*; a practice still followed by the modern Greeks. Plin. *ubi supra*.

Such are the principal facts known respecting the celebrated ancient wines, which, as Chaptal justly remarks, appear in general to have rather deserved the name of *extracts* or *syrops* than wines. They must have been sweet and little fermented, and consequently have contained a very small proportion of alcohol. Indeed it is difficult to suppose how they could contain any spirit whatever, or possess in consequence any intoxicating properties.

The above remarks, however, can be only applicable to those wines which the refinements of luxury or caprice had rendered valuable, from their uncommon occurrence, or the difficulty with which they were procured. It is certain that the ancients were well acquainted with the fermentative process, and ordinarily took advantage of it in the formation of their wines: hence it is extremely probable that the wines used in the primitive states of society, and perhaps at all times by the common people, consisted simply of the fermented juice of the grape, and therefore differed in no respects whatever from the wines in common use at the present time.

General Principles of Wine-making.—We shall consider this interesting subject under two principal points of view: 1st, The manufacture of wine from grapes; and 2d, From other fruits.

1. The manufacturing of wine from grapes is liable to be influenced by a great variety of circumstances, such as *climate, soil, aspect, season, &c.*; of some of the most important of which we shall take a cursory view.

The vine is a native of the middle regions of the temperate zone, that is to say, between the latitudes of 25° and 50°, and here only does it flourish and mature its fruit in absolute perfection. Indeed a belt comprised between the latitudes of 40° and 50°, may be said to include all the most celebrated vineyards of the northern hemisphere; those, namely, of Spain, Portugal, France, Italy, Austria, Styria, Carinthia, Hungary, Transylvania, and part of Greece. The vine grows beyond the latitude of 50°, but its juices are auster, and without the requisite degree of saccharine matter to form good wine. The fine aromatic odour and flavour of its fruit also are not developed much beyond this latitude. In the southern hemisphere, which is colder than the northern, the vine flourishes somewhat nearer the equator.

The vine grows in every soil, but that which is light and gravelly is best adapted for its cultivation. It flourishes extremely well also in volcanic countries. Thus some of the best wines in Italy are made in the neighbourhood of Vesuvius. The famous Tokay wine is also made in a volcanic district, as are several of the best French wines; many parts of the south of France bearing evident marks of extinct volcanoes. The vine also flourishes well in primitive countries, and especially among the debris of granite rocks: thus the celebrated Hermitage wine is made from a soil of this description.

The same climate, soil, and mode of culture, however, often produce wines of very different qualities. Position and aspect alone, all other circumstances being the same, make a prodigious difference. The same vineyard, for example, according as its different parts have a northern or southern aspect, will produce wines of opposite characters, as will also the same hill, at its top, middle, and bottom. The

aspect most favourable for a vineyard is upon a rising ground or hill facing the south-east, and the situation should not be too confined:

“————— apertos
Bacchus amat colles.”

If the soil be not favourable for the vine no art can make it so. Manure of different sorts will indeed render the fruit more abundant, but the wine will suffer in quality. The best manure is stated to be the dung of pigeons or poultry. Burnt sea-wrack also is a favourite manure with some. Fat and putrid manures are absolutely to be rejected, as they destroy the wine altogether, by vitiating its flavour.

The qualities of wines are very much affected by the seasons. In cloudy and wet seasons the wine is always inferior. Rain is most to be dreaded at the season of the vintage. Moderate rains just after the season of bloom are of great advantage, and cause the fruit to swell very rapidly. Rough winds are very prejudicial to vineyards. Mists are still more so, especially during the season of bloom, as they are apt to destroy the flower, and consequently the fruit: the reason of this is perhaps not very evident, but it seems to depend in part upon the rapid evaporation of the moisture left by the fogs, when the sun breaks through them, and the great and sudden change of temperature which takes place in consequence. Too great a degree of heat is injurious to the vine; the perfection of their fruit, as well observed by Chaptal, depends upon a due equilibrium between the quantity of water affording aliment to the plant, and the degree of heat necessary to elaborate this water into its juices.

Towards the northern limits of the vine country, the plants are always supported on poles, and in cold and wet seasons they sometimes strip off the leaves, or twist the stalks of the clusters, in order to suppress vegetation and facilitate the ripening of the grapes. The latter practice was not unknown to the ancients: “*Ut dulcior præterea fierent, aservabant uvas diutius in vite, pediculo intorto.*” Pliny. But in warmer climates, on the contrary, the earth requires to be shielded from the heat, and here the vine is generally left to spread over the ground, and thus by its foliage to protect the soil, as well as its fruit, from the direct rays of the sun. With respect to the best methods of pruning and training vines, see the articles VINE, and VITIS.

Of the Vintage.—It is of the utmost importance in the manufacture of wines, to attend to the precise moment when the grapes have arrived at their full maturity; and then, and not before, ought the vintage in general to commence. This may be known, according to Chaptal, by the following signs.

1. The green end of the cluster becomes brown.
2. The cluster becomes pendant.
3. The seed loses its hardness, and the skin becomes thin and transparent.
4. The cluster and seeds are easily detached.
5. The juice is sweet, bland, thick, and clammy.
6. The kernels of the seeds are free from glutinous matter.

The fall of the leaves denotes rather the approach of winter than the maturity of the fruit, especially in the more northern climates. This therefore is a fallacious sign. Nevertheless, when the frost has been so severe as to destroy the leaves, it will seldom be proper to delay the vintage much longer, as the fruit can hardly be expected after this to become ripe; and by delay it may stand a chance of being spoiled entirely.

On the contrary, in the manufacture of particular wines, the grapes are permitted to remain till they wither, or they

are gathered and dried in the sun. Thus the celebrated Tokay wine is made of dried fruit, as are also many of the luscious wines of Italy. Some of the French wines likewise are made with fruit that has been suffered to ripen and wither upon the vines.

It is desirable in general that the weather should be settled, and the soil and fruit dry during the vintage. It is therefore recommended to abstain from gathering till the sun has dispersed the dew. As a general rule, this is proper; but in Champagne they commence gathering the fruit before the sun is risen, and cease their labours about nine o'clock, unless there be a fog, when they continue to gather all day; by these means they improve the whiteness and briskness of their wine, which are the qualities that chiefly render them celebrated. They also increase their quantity. Thus it is found in Champagne, that they gain a tun in every twenty-four where they collect the fruit moist with dew, and a great deal more if there happens to be a fog.

When the fruit is ripe, a proper number of experienced hands should be procured, so as to be able, in a single day, to fill the fermenting tub or vat, in order to ensure an uniform degree of fermentation. Women are commonly employed for the purpose, but the presence of an intelligent male overseer is absolutely necessary. In some parts of France the fruit is separated with scissors; in others with the nail; and in Champagne they use a knife. The scissors is undoubtedly preferable, as it does not shake the flock. The ripe fruit only should be collected, if the object be to make good wine, and what is unripe or decayed should be carefully rejected; indeed they have always two or three separate vintages in those countries, where they are careful of the quality of their wines; and the wine made first is always considered the best. In those parts, on the contrary, where the wine is chiefly distilled, as in Languedoc and Provence, they usually collect all the fruit indiscriminately at one time. In some districts, where the finest wines are made, as in Bourdeaux, &c. the fruit is carefully picked, and only the prime of the clusters taken. On the contrary, they carefully avoid having the fruit too ripe in Champagne, and other districts where sparkling wines are chiefly manufactured, and prefer the presence of a certain proportion of unripe fruit. It need scarcely be remarked, that the greatest care should be taken to prevent the fruit from being bruised or otherwise damaged.

The next important step is the management of the fruit after it has been collected. In different countries different preliminary steps are pursued before the fruit is submitted to pressure. Thus in Spain, especially in the neighbourhood of St. Lucar, they leave the fruit exposed for two days to the rays of the sun. In Lorraine, part of Italy, in Calabria, and the island of Cyprus, as before observed, they dry the fruit completely, and this is the case in the manufacture of all the rich white wines.

A question that has been much agitated is, whether it be advantageous to strip the grapes from the stalks and remove the latter, or suffer them to remain. Both these methods have their advocates; but Chaptal remarks very properly that neither ought to be followed exclusively. It is true, the same celebrated chemist observes, that the stems have a rough and austere taste; but this appears to be of advantage to some wines, especially those made in the more northern districts, where the slight astringency imparted by the stems corrects their insipidity, and appears to have the property of making them keep better, perhaps by rendering the fermentation more complete. In the neighbourhood of Bourdeaux, indeed, they remove the stalks from the red grapes in the manufacturing of their best wines, but they modify that part of the process in some

degree according to the ripeness of the fruit: when the fruit is unripe, or has been injured by the frost, they remove nearly the whole of the stalks, but if the fruit be over-ripe they leave a very large proportion of them. A certain portion, however, is always permitted to remain with the view of facilitating the fermentative process, and rendering it more perfect. From the white grapes, the stalks are never removed. In short, in the colder districts, where the wines are of an inferior quality, or where the object is to render the wines as strong as possible, with the view of distilling them, the stems in general do not require to be removed; but in warmer countries, where the finer-flavoured and richer wines are manufactured, every thing liable to affect these desirable qualities is to be carefully removed, and the stems among the rest. The stems are separated in various ways: sometimes by agitating the grapes in the vessels in which they are deposited with three-pronged forks, sometimes by coarse sieves made of osiers, &c.

The next important step is bruising the fruit, which is generally performed by treading them with the feet in perforated tubs or baskets placed over the vat or tub destined to receive the must. This mode of bruising grapes, though as ancient perhaps as wine-making itself, is very imperfect, as a great deal of the fruit remains unbroken. In England we should adopt the use of machinery.

Of Fermentation, the Circumstances affecting it, Phenomena, Products, &c.—The juice, or *must*, as it is termed, is no sooner in the vat than it usually begins to ferment. The vat is a capacious vessel made of wood or sometimes of masonry, and its size corresponds, or ought to correspond, with the quantity of wine to be made. Before it is used, it requires to be thoroughly washed, and its sides in France are usually covered with lime, which has the effect of saturating a portion of the malic and other acids which exist in abundance in the *must*.

The fermentative process has been already described (see FERMENTATION); we shall therefore be very brief upon the subject here, and confine our attention principally to a concise recapitulation of the particulars, in order to present our readers with a general and connected view of the art of wine-making.

The vinous fermentation is influenced by several circumstances, such as temperature, presence of the air, the volume of the must, &c. The must of the grape requires a temperature of at least 55°, to enable it to commence the fermentative process. Some have denied that the presence of the air is necessary to fermentation. The recent experiments of Gay Lussac, however, seem to prove the reverse. This celebrated chemist found that the must would not begin to ferment in close vessels, but that the introduction of a little oxygen instantly set it going; the oxygen being first rapidly absorbed. Perhaps we may explain the opposite conclusions of different experimentalists upon this subject, by supposing that the presence of oxygen, though necessary to enable the must to commence fermentation, is not necessary to support it afterwards. The fermentative process is much influenced by the bulk or quantity of the must. It is a well-established fact, that the greater the quantity the more violent is the fermentation. An experienced manufacturer of wine, therefore, will take care to proportion the quantity of must to the qualities of his fruit, or rather perhaps to those of the wine which it is his object to procure: the sweeter and more luscious the must, the greater the quantity in general, which it will be proper to submit to the fermentative process in one mass.

Other important circumstances which influence the fermentative process are the requisite quantities and due relative proportions

proportions to one another of the necessary principles. The saccharine and fermentative principles, tartar and water, are the principles (as explained under the article FERMENTATION) essential to the production of wine. The sweetest grapes do not always make the best wine, nor actually contain the greatest proportion of sugar, at least of real sugar, such as is proper for the formation of alcohol. An experienced taste, it is said, can readily distinguish between a really *saccharine* grape and a *sweet* grape; and consequently pronounce *à priori* whether it be adapted for making good wine or not. Pure saccharine matter, however, will not ferment alone, but requires a certain proportion of other principles to put it in motion. When the must contains too large a proportion of water, the fermentative process is feeble, and the wine is consequently bad. The ancients obviated this, as we before mentioned, by boiling the must; a practice still sometimes followed in the northern districts, especially in wet seasons. The same object is gained also by drying the fruit; and sometimes by the introduction of lime into the vat. The juice of the grape always contains a certain proportion of tartar. This quantity is greater in general as the quantity of sugar is less. If the juice contains too large a proportion of sugar in relation to the tartar, it is customary to add a portion of the latter principle. On the contrary, if the saccharine principle be deficient and the tartar in excess, sugar is to be added.

The fermentative process is accompanied by the production of heat, by the disengagement of carbonic acid gas, and the formation of alcohol. These phenomena have been already discussed under the article above alluded to. Another important circumstance, however, which takes place during this process, is the *colouring* of the must. The juice of the black grape, as well as of the white, is nearly colourless; and if the fermentation be not permitted to take place in contact with the husks or *marc*, a colourless wine is obtained in all cases. The colour of red wines is derived from the *marc*, by permitting the wine to ferment in contact with it, the colouring principle of the *marc* or husks being soluble in alcohol. Hence, when alcohol begins to be developed by the fermentative process, it acts upon the colouring principle and dissolves it, and the must becomes coloured. The following are the principal facts connected with this part of the subject. The wine is more coloured the longer the fermentative process is continued, and *vice versa*. The wine is more coloured in proportion as the fruit is more ripe and less watery. Wine obtained by pressure is more coloured than other wine, and lastly wines manufactured in the south are in general deeper coloured than those produced in more northern districts.

Great attention and practical knowledge are required in managing the fermentation properly, as on this important process depend entirely the future qualities of the wines. The same fruit in different seasons, and from various causes, requires to be managed differently; and almost every kind of wine requires a different, and, in some cases, even an opposite, mode of treatment. Thus the fine *bouquet* of Burgundy is completely dissipated by a too violent or lasting fermentation; while, on the contrary, the fermentation of the strong wines of Languedoc, celebrated chiefly for the quantity of alcohol which they contain, ought to be long and complete. In Champagne, as we formerly mentioned, they collect the fruit destined to form their white wines while moist with dew or mist: on the contrary, in the manufacture of their red wines, they prefer fruit as dry as possible. In the former case, the fermentative process is so languid, as often to require a gentle heat; in the latter, so violent, as to require to be moderated. Weak wines ought in general to be fer-

mented in casks; strong wines in the vat. No general rules, however, can be given that will apply in all instances; but the processes must be varied according to circumstances, and the judgment of the manufacturer.

The fermentative process, for obvious reasons, is most difficult to manage in the northern districts, where the fruit is more imperfect. To encourage the process, they sometimes introduce a little warm must to the bottom of the vat by means of a long funnel. They also agitate it frequently, and to preserve a due degree of temperature, cover the vat with blankets, or heat the room artificially.

The theory or rationale of the fermentative process has been explained, as far as it is known, under the article FERMENTATION, before alluded to; we shall therefore pass it over entirely here, and confine our attention to practical points only.

A most material point in the manufacture of wines is to know the precise moment when the fermentative process has been carried far enough, and the means necessary to prevent its getting farther than this point. In the wine countries almost every manufacturer boasts of his knowledge in these particulars, and often adopts different methods. Chaptal lays down the following rules to be attended to.

1. The wine ought to ferment so much the less time as it contains less saccharine matter. Thus the light wines of Burgundy require to ferment no longer than from six to twelve hours.

2. The must ought to ferment a less time in the vat when it is intended to retain the carbonic acid gas, and make sparkling wines. In this case, the must is seldom left longer in the vat than twenty-four hours before it is put into casks; and frequently it is introduced into the casks as soon as it is separated from the fruit; by these means the fermentation is checked, and the carbonic acid gas prevented from escaping.

3. The fermentation ought to be of shorter duration, in proportion as it is the object to obtain wines more free from colour. This should be, therefore, particularly attended to in the manufacture of those wines where the absence of colour is an essential requisite.

4. The fermentative process is more active in warm weather, and when the mass is large, &c. than under the opposite circumstances; and therefore, *ceteris paribus*, is sooner completed.

5. When the object is to preserve to the wine the original perfumed flavour of the grape, the fermentation requires to be checked sooner than under ordinary circumstances.

6. On the contrary, the fermentation requires to be continued longer in proportion as the must is more thick, and the saccharine matter more abundant.

7. It will also require to be longer when the object is to manufacture wines for distillation.

8. It will be longer in cold weather, and especially if the fruit has been gathered on a very cold day.

9. Lastly, it will be longer in proportion as it is the object to make a deeper coloured wine.

These principles steadily kept in view will perhaps be sufficient, with a little practice, to enable any person of ordinary knowledge and powers of observation to decide upon the important points in question.

Great care is requisite in the preparation of the casks for receiving the wine. When they are new, they will spoil its flavour if not prevented. For this purpose, boiling-water, holding salt in solution, is introduced into them, which is frequently agitated, and permitted to remain in them a long time. After this they are to be washed out with a portion of boiling must in a state of fermentation, or sometimes with a little wine, &c. If the casks are old but sweet, the top is merely

merely taken out, and the tartar removed; they are then washed well with warm water. If the casks have acquired a bad odour, Chaptal recommends to commit them to the flames; for though it may be possible to cover in some degree their bad odours, yet they are very likely to re-appear and spoil the wine.

The vessels being ready, the wine is introduced into them, for which purpose it is drawn off from the vat by a cock placed a few inches above the bottom into an open vessel, from whence it is conveyed to the casks. That portion of the wine resting immediately over the must is termed *surmont* in Burgundy. This is carefully defecated, as it constitutes the most delicate and palest of the wine. The liquor is drawn off till the head comes in contact with the *marc*. The head is then carefully removed, and the *marc* is subjected to repeated pressure. The wine thus farther obtained is usually mixed with the rest. That produced by the first pressure is strongest; that obtained by the last is usually more harsh and coloured. Sometimes, however, when it is the object to make vinegar, the *marc* is pressed but once. At other times, they keep the wine obtained by all the different pressures in separate casks. In Champagne they usually mix together the wines obtained by the different pressures, though they are known by different names. The wines obtained without any pressure, or a very slight one, they call *vins gris*; those obtained by the first and second pressure, *ail de perdrix*; those by the third, *vin de taille*, which are most coloured, though sufficiently agreeable.

The *marc* is employed in various ways in the different districts. Some submit it to distillation; others, especially in the vicinity of Montpellier, prepare verdigris from it; others vinegar. In some districts, they feed cattle with it; in others, they burn it for the sake of the potash it yields, &c.

Of the Management of the Wine in the Casks.—The wine receives its last degree of elaboration in the casks; this consists in a sort of fermentative process, to which the name of *insensible fermentation* has been applied. Almost immediately after the wine is introduced into the casks, a scum begins to be formed upon its top, and escapes by the bung-hole, which at first requires to be covered slightly only with a leaf or tile. In proportion as the fermentation subsides, the mass of wine diminishes in bulk; and they watch this cautiously, in order to supply its place from time to time with new wine, so as to keep the cask always full: this process is denominated in France *ouiller*, which may be rendered *filling up*. In some districts they *fill up* every day during the first month, every other day during the second, and every eight days afterwards, till the time of racking. This is the method they adopt with the wines of Hermitage. In Champagne they permit the *vins gris* to ferment in casks for ten or twelve days, and when the ebullition has ceased, they close the bung-hole, leaving, however, a small spigot-hole by its side, which is permitted to remain open for eight or ten days longer; after which they close this with a plug, in such a manner as to be able to open it at pleasure. When the bungs are introduced, they *fill up* every eighth day by the spigot, for twenty-five days. After this every fifteenth day, for one or two months; and finally, every two months during the whole time the wine remains in the cellar. When the season has been wet and unfavourable, and the wines want body, or when it has been dry and hot, and they are too rich, twenty-five days after they have been made, they roll the casks five or six times, in order to mix the grounds, and re-excite the fermentative process, and this they repeat every eighth day for a month.

The fermentation of the Champagne wines, which are designed to be brisk and sparkling, is very long and tedious.

It is generally understood that they will be sparkling, provided they are bottled any time between the vintage and the following May, and that the nearer the vintage the brisker they will be. It is, however, generally taken for granted, that they will be sufficiently sparkling if bottled about the middle of March. Wines begin to sparkle in about six weeks after they have been bottled; those, however, produced on mountains become sparkling sooner than others. Wines bottled in June and July will be very little sparkling, and quite *still* if bottled so late as October and November.

In Burgundy, after the fermentation has relaxed in the cask, they put in a bung pierced with a small hole, in which they introduce a plug that can be easily removed at pleasure, in order to suffer the gas that may be extricated to escape. In the district of Bourdeaux, they begin to *fill up* eight or ten days after the wine has been introduced into the cask. A month after this they introduce the bung, and *fill up* every eight days. At first they bung the casks loosely, and then fasten them down by degrees, without running any risk. The white wines are racked and sulphured in December, and these require much more care than the red wines, from their containing more sediment, and their being more liable to become ropy. The red wines are not racked till towards February or March, and as these are much more apt to become sour than the white wines, they require to be kept in cooler cellars during the summer. There are some who, after the second racking, turn the casks so as to place the bung on one side; and thus the casks being hermetically sealed from there being no loss, there is no need of *filling up*. They then rack off annually, at any time of the year they find it convenient.

Methods nearly similar are adopted in other wine countries; hence it will be needless to repeat them. We shall, however, give a short account of the methods followed in the manufacture of *Port*, *Madeira*, and *Sherry*, the most popular wines of this country.

In *Oporto*, the complete fermentation of the must takes place in the vat. The wine is then introduced into large tuns, capable of holding twenty-five pipes each; and at this stage the brandy is added according to the judgment of the manufacturer.

In *Madeira*, the second or insensible fermentation is carried on in casks, and the wine is racked from them at the end of three or four months, at which time a portion of the brandy is added. The remainder is reserved to be mixed at the time of exportation.

In the manufacture of *Sherry*, the grapes are first slightly dried, and sprinkled with quick-lime. They are then wetted with brandy on being introduced into the prefs, and a portion of brandy is added to the must before the fermentation commences. The subsequent processes consist in repeated rackings at intervals of a month or two, till March, brandy being added at each racking.

The object of racking the wines is to separate the dregs consisting of tartar, &c. deposited from the wine, and which, if left, are liable to render it sour, by re-exciting from time to time the fermentation. The tendency to fermentation is counteracted by a process termed *sulphuring*, and the spontaneous separation of the dregs is rendered more complete by CLARIFICATION, which see. See also FINING and FORCING.

The *sulphuring* of wines consists in impregnating them with the vapours of burning sulphur, or sulphurous acid, and is generally effected by burning sulphur-matches in the casks. (See MATCHING.) These matches are made in different ways, aromatics being sometimes mixed with the sulphur; but the sulphur is the only useful and necessary ingredient.

Sometimes

Sometimes a wine highly impregnated with fulphurous acid is prepared, a little of which mixed with the rest answers the purpose of burning matches in the cask. Other substances, according to Dr. Macculloch, answer the same purpose as *sulphuring*; namely, the *black oxyd of manganese*, and particularly the *sulphite of potash*. A drachm of which salt is sufficient for a pipe of wine, and is very effectual in counteracting the fermentative process. The theory of these processes is very obscure.

We have before observed that the mere racking of wines is not sufficient to render them pure, and various methods are adopted at the racking periods to render this operation more effectual, and these altogether constitute the process termed *clarification*.

Lord Bacon mentions a practice among the ancients of putting wine into vessels well stopped, and letting it down into the sea. That this practice is very ancient is manifest from the discourse of Plutarch (*Quæst. Nat. 27.*) about the efficacy of cold upon must.

Different periods, as before-mentioned, are chosen in different districts for racking wines. Thus the wines of Hermitage are racked in March and September, those of Champagne about the middle of October, the middle of February, and the latter end of March. If possible, a serene and settled state of the atmosphere, and a dry and cold day, should be chosen for the purpose, as the wine is always turbid in damp close weather, and during the prevalence of southerly winds.

In racking wines, it is in general desirable to expose them as little as possible to the atmospheric air. In some districts, a syphon is employed for the purpose. In Champagne they use a fort of pump. Dr. Macculloch recommends that the wine should be transferred from one cask to another by means of a leather hose, and this method is undoubtedly preferable. For clarifying wines, a great variety of substances are employed. Ifinglass and albumen either from eggs or blood are the most common; but gum, starch, rice, milk, the shavings of beech-wood, gypsum, sand, &c. are used in different wine countries. An ounce of ifinglass, or about eighteen or twenty whites of eggs, are sufficient for one hundred gallons of wine.

Two very important circumstances in the practice of wine-making require yet to be mentioned; these are the *medication* of wines, and the means of *remedying those diseases* to which they are liable.

The *medication* of wines consists in altering the colour, the flavour, or the strength of any given wine, or in so mixing two or more together, as to produce a compound differing from, or superior to, either. It is difficult to give any general rules for this purpose, and the proper management of the processes depends chiefly upon the experience and taste of the maker.

It generally happens that when two wines are mixed, the fermentative process is partially renewed, or the mixture is technically said to *fret*, whence the practice itself has derived the name of *fretting in*. Mixed wines appear to unite into one durable and homogeneous liquor, only in consequence of this fermentation. It is therefore desirable, if possible, to mix wines only at those periods when they both shew a tendency to *fretting*, which, according to Chaptal, in the wine countries, appears to be at three principal seasons of the year, *viz.* when the vines begin to shoot, when they are in flower, and when the fruit begins to acquire colour. The wines being then proportioned according to the fancy or experience of the maker, a strong fermentation is excited, which is still farther assisted by agitation. The wine thus becomes homogeneous, and shews no more tendency to far-

ther change than if it had been originally produced by one operation; and the repetition of the processes of *fining and racking* renders it perfect.

In wine countries, particular wines, distinguished either by their strength, harshness, colour, or flavour, are often manufactured for mixing with others, and are applied according to circumstances. For making such wines, different fruit and peculiar management are often resorted to. The usual faults of wines requiring correction are, *sweetness*, *dryness* bordering on *acidity*, and excess or defect of *briskness*. Connected also with this part of the subject are the means of imparting to wine *colour*, *flavour*, and *strength*, and other remarkable properties. *Sweetness* arises from the presence of too much saccharine matter, and may be generally remedied by prolonging the fermentation. On the contrary, when the fermentation has been carried so far as to decompose the whole of the sugar, the wine is said to be *dry*; and if the original quantity of sugar has been rather defective, it will have a strong tendency to become sour. The remedy in this case is, to add sugar, or sometimes brandy. The modes of ensuring a due degree of *briskness* in those wines intended to possess this quality have been already pointed out.

Many of the processes followed in imparting *colour*, *flavour*, *strength*, &c. to wines, are unknown to the public, and confined to the cellars of the manufacturer or the merchant. The general principles, however, are sufficiently obvious. The *roughness* and *colour* of red wines are derived, as we formerly stated, from the husks of the fruit; and when it is wished to impart these qualities in a higher degree, the manufacturers sometimes mix a certain portion of wild and high-coloured grapes with the other fruit. At other times, various astringent and coloured drugs are employed, as catechu, kino, logwood, &c.: popular ingredients are the juices of sloes or elderberries. The chips of oak and beech-wood are also employed. With respect to yellow tints, these can be all accurately imitated by means of burnt sugar. As to *flavours*, in general those which are foreign and unusual are commonly unpleasant. Custom, however, has reconciled us to many. The ancients, as formerly mentioned, seem to have been much more accustomed to artificial flavours than the moderns, and the most in request was the turpentine or resinous flavour, which was imparted by means of chips of fir-wood, a practice still followed in modern Greece. In Madeira wines, as well as those of Xeres and San Lucar, it is the practice at present to use sweet and bitter almonds; hence the *nutty* flavour of these wines. In Egypt, the flower of the vine itself has been employed from time immemorial, and is still used in different wine countries; its odour is very like that of mignonette, which may be doubtless substituted for it. Raspberries, orris-root, elder-flowers, worm-wood, and a variety of other substances, are employed for a similar purpose. In using these different articles, the established practice is to suspend the flavouring ingredients in the cask a few days during the stage of insensible fermentation; by which means their flavour is retained without a chance of being dissipated. Where the *strength* of wine is deficient, brandy is added, according to circumstances; and to render the mixture of this more complete, it should be added while the process of insensible fermentation is going on. If there be a necessity to add it after the wine is completed, it should then be managed by the *fretting-in* process.

The last of the circumstances connected with wine-making is the means of *obviating those diseases* to which wines are liable.

One of the most common diseases of weak wines is *acidity*.

Strong

Strong wines, for obvious reasons, seldom become four. When acidity is present only in a very slight degree, it may be palliated considerably by fugar, or by the addition of must concentrated by boiling. It is obvious, however, that the acid can only be got rid of by neutralizing or destroying it. For this purpose, the alkalies and alkaline earths have been employed, but they impart a disagreeable flavour to the wine. Of these substances, lime is the safest and best. It was formerly the practice to employ lead, in some form or other, for counteracting acidity in wines; but we trust that this murderous practice has been long since laid aside. *Ropiness* is another disease to which wines are liable. This occurs more particularly in those which contain a good deal of extractive matter. It may be much relieved, and sometimes cured, by exposing the bottles to the sun and air, by agitating and subsequently uncorking them, by adding a small quantity of vegetable acid, and by fining. The last disease we shall notice is perhaps the most formidable of any, namely, a *mustiness*, or other *ill-flavour* communicated by the cask or cork. This appears to be, in general, absolutely incurable, though it may be sometimes diminished by agitating the wine in contact with the air, or by the introduction of common air or carbonic acid by pumping. Such is a summary account of wine-making from grapes, as practised in the countries where that delicious fruit comes to perfection, and more especially in France. (See Birch's Hist. of the Royal Society, vol. i. p. 156.) We come now to consider,

2. *The Manufacturing of Wines from other Fruits, or artificial Wines.*—In the above sketch we have endeavoured to present our readers with a general view of the principles of wine-making, at the same time that we described the practice. These principles are equally applicable to the manufacture of wine from all sorts of fruit; we shall therefore take the present opportunity of briefly recapitulating them here, as they cannot be too strongly impressed upon the memory, and as they at the same time constitute the most appropriate introduction to the present section that occurs to us.

The juice of the grape consists of a large proportion of water, holding in solution certain proportions of *saccharine matter*, of the *sweet or fermenting principle*, which appears to be a modification of the saccharine principle, of *various acids*, especially the tartaric and malic, and of various ill-defined *extractive matters*. These principles, left to themselves for a short time in a medium temperature, soon begin to re-act upon one another, and some of them at length undergo remarkable changes. This process is termed *fermentation*, and constitutes the grand principle of wine-making. When this process has begun to subside, it will be found that the greater portion of the saccharine principle has disappeared, and that its place is supplied by a corresponding portion of ardent spirit or alcohol. This is the most striking feature of the change that has taken place, but all the other principles of the juice or *must* appear to have undergone likewise some change either in quality or quantity. In short, the sweet and crude *juice* of the grape is found to be converted into *wine*.

In this state, the *wine* is introduced into casks, where it undergoes further changes, and is matured by a modification of the fermentative process, which has been called the *insensible fermentation*. This is a most important step in the process of wine-making, as by different modes of management in this stage almost the whole of that infinite variety which exists among wines is produced. Here also it is that all foreign substances designed to impart flavour, &c. to wines are in general introduced with the greatest pro-

priety. When the *insensible fermentation* has been carried to the point desired, it is checked by the processes of *racking*, *sulphuring*, *clarification*, &c.; and thus the wine is rendered capable of being preserved at any point or state we choose.

Let us now apply these principles to the manufacture of wines from other fruits.

We start upon the grounds that artificial wines are intended to be imitations of wines prepared from grapes. In the first place, therefore, we have to prepare a juice or must similar to the juice or must of the grape in its general composition. Now, no fruit whatever yields a juice precisely similar to that of the grape. In our northern climate more especially, the saccharine principle, which is the fundamental principle in wine-making, exists in very minute proportion in most fruits. It must be, therefore, supplied artificially. The tartaric acid, or rather *tartar*, which appears to be another essential principle in wine-making, is likewise wanting in most of our fruits. This, therefore, must be supplied. On the contrary, other principles, and particularly the malic acid, appear to exist in too large a proportion in most of our fruits, which, in their natural state, are thus better adapted for making *cyders* than wines. To get rid of the malic acid, and to prevent its deteriorating effects, as well as the deteriorating effects of other foreign principles, is difficult, or perhaps impossible; and this will doubtless always render artificial wines in general inferior to those of the grape, though very near approaches may be made by judicious management.

The practical mode of obviating these difficulties is to dilute the juice of the fruit to such a degree, that a given quantity of it when diluted shall contain no more of the malic acid, for example, than a given quantity of the juice of the grape; and, as before observed, to supply artificially the two grand principles, sugar and tartar, which are wanting. Having thus prepared an artificial must, as nearly resembling in its composition that of the grape as possible, the application of the other principles will be obvious, as we have nothing to do but to manage, in general, all the subsequent processes precisely as if we were operating upon the must of the grape. We shall now, therefore, descend from generals to particulars, and, after having made a few remarks upon our native fruits, endeavour to point out the modes in which the more important foreign wines may be best imitated by them.

Fancy or caprice has led to the formation of wine from an infinite variety of substances, and almost every good housewife boasts of some favourite *receipt* for making wines from what nature never intended for the purpose. Such compounds hardly deserve the name of *wine*; we shall, therefore, principally confine our attention to *fruits*. The following are the domestic fruits most usually employed for the purpose:

Gooseberry, and three varieties of currant.
Strawberry, raspberry, blackberry, mulberry.
Sloe, damson, elderberry.
Quince, cherry.
British grapes.

To them may be added the foreign fruits

Raisins.
Orange, lemon.

The gooseberry and currant are of all others the fruits most commonly employed for the fabrication of artificial wines; and, perhaps, upon the whole, they are best adapted for the purpose. When used in their green state, both gooseberry and currant may be made to form light brisk

WINE.

brisk wines, falling little short of Champagne. Ripe gooseberries are capable of making sweet or *dry* wines; but these are commonly ill-flavoured, particularly if the bulk has not been carefully excluded. Ripe currants, if properly managed, make much better wines than gooseberries. These fruits are much improved, according to Dr. Macculloch, by boiling previously to fermentation. This, he states, is particularly the case with the black currant, which, when thus managed, is capable of making a wine closely resembling some of the best of the sweet Cape wines.

The strawberry and raspberry are capable of making both *dry* and sweet wines of agreeable quality. As commonly managed, however, their peculiar flavour is dissipated in the process; hence, as Dr. Macculloch observes, little is gained by their use to compensate for their comparatively high price. A simple infusion of these fruits, in any flavourless currant wine during the period of insensible fermentation, will, with greater cheapness and certainty, ensure the production of their peculiar flavour. The blackberry and mulberry are capable of making coloured wines, if managed with that view: they are deficient, however, in the astringent principle; nevertheless, they may be occasionally employed with advantage when a particular object is to be gained.

The sloe and damson are so associated in qualities, that nearly the same results are obtained from both. Their juice is acid and astringent; and hence they are qualified only for making *dry* wines. By a due admixture of currants or elderberries with sloes or damsons, wines not much unlike the inferior kinds of port are often produced. The elderberry is capable of making an excellent red wine. Its cheapness also recommends it. It does not, indeed, possess any great degree of flavour, but it possesses no bad one, which is a negative property often of great importance in artificial wine-making.

The quince, from its analogy to the apple and pear, is better qualified for making a species of cyder than wine. The cherry produces a wine of no very peculiar character. If used, care should be taken not to bruise too many of the stones, otherwise a disagreeable bitter taste will be imparted to the wine.

Grapes of British growth are capable of making excellent sparkling and other wines, by the addition of sugar. Dr. Macculloch informs us, that he has succeeded in making wines from immature grapes and sugar so closely resembling Champagne, Grave, Rhenish, and Moselle, that the best judges could not distinguish them from foreign wines. The grapes may be used in any state, however immature; when even but half grown and perfectly hard they succeed completely.

The cottagers in Sussex, says Dr. Macculloch, are in the habit of making wine, almost annually, from the produce of vines trained on the walls of their houses. Many individuals through various parts of the southern counties, and even as far north as Derbyshire, practise the same with success. But the experiment is well known to have been made for many years on a large scale, and with complete results, at Pain's-hill, by the Hon. Charles Hamilton, in a situation with respect to soil and exposure of which parallel instances are to be found throughout the country, and produced from land of no value whatever for the ordinary purposes of agriculture. That our ancestors made wine from the produce of their vineyards there can be no doubt, and Dr. M. justly remarks, that we can still make by far better wine from our grapes, even as produced at present, than from any other fruit whatever. These, therefore, are cogent reasons for the cultivation of the vine, especially as, the same

gentleman observes, we might, with care, inure and domesticate to our climate many of the richer and more delicate varieties of southern latitudes. See VINE, and VARIETIES; under the last of which articles some interesting experiments on this subject are related.

Raisins are extensively used in this country for making domestic wines, and also for the fraudulent imitation and adulteration of foreign wines, although not a native fruit; therefore they deserve to be mentioned here. When properly managed, they are capable of making a pure and flavourless vinous fluid, well adapted for receiving any flavour which may be required, and thus of imitating many wines of foreign growth. See the close of this article.

The orange and lemon are likewise used for making domestic wines. Upon the whole, however, they are not very well adapted for the purpose, as they contain too much acid, and too little of the extractive and of the sweet or fermentative principle.

From what has been said of the manufacture of wine from grapes, our readers will observe, that different methods are pursued, according to the kind of wine which it is intended to make. Now these remarks are equally applicable to artificial wines, in the manufacture of which it is absolutely necessary that the maker should determine beforehand upon the kind of wine which it is his object to produce, and to modify his processes accordingly. We may, with Dr. Macculloch, consider wines as of four general descriptions: *sweet* wines; *sparkling* or *effervescent* wines; *dry* and *light* wines, analogous to hock, grave, and Rhenish, in which the saccharine principle is entirely decomposed during fermentation; and lastly, *dry* and *strong* wines, as Madeira and sherry.

Those of the first and most simple class are the *sweet* wines, or those in which the fermentative process has been incomplete. It is to this class that by far the greater number of our artificial wines bear the greatest resemblance; a resemblance, says Dr. M., so general as to shew that few makers of this article possess sufficient knowledge of the art to enable themselves to steer clear of what may be firmly called the radical defect of domestic wines. *Sweet* wines may be made from almost any ripe fruits. Those most generally employed, however, are the gooseberry and currant. We shall suppose that we wish to make the quantity of ten gallons of sweet wine from one or other of these fruits.

For this purpose, the following are the proportions and other circumstances to be attended to. Forty pounds of fruit are to be introduced in a clean and sufficiently capacious tub, in which it is to be bruised in successive portions, by a pressure sufficient to crush the berries without breaking the seeds, or if gooseberries be employed, without materially compressing the skins. Four gallons of water are then to be poured into the vessel, and the contents are to be carefully stirred and squeezed in the hand until the whole of the juice and pulp are separated from the solid matters. The materials are then to be permitted to remain at rest for a period of from six to twenty-four hours, when they are to be strained through a coarse bag by as much force as can be conveniently applied to them. One gallon of fresh water may afterwards be passed through the *mare*, for the purpose of removing any soluble matter which may have remained confined. From thirty to forty pounds of sugar, according to the desired strength and sweetness of the wine, and about six ounces of cream of tartar, or, what is better, crude tartar, are now to be dissolved in the juice thus procured, and the total bulk of the fluid made up with water, to the amount of ten gallons and a half.

The liquor thus obtained is the artificial *must*, which is

equivalent to the juice of the grape. It is now to be introduced into a tub of sufficient capacity, which is to be well covered, and placed in a temperature varying from 55° to 60°. Here it is to remain two or three days, more or less, according to the symptoms of fermentation which it may shew, and from this tub it is to be drawn off into the cask, where the fermentative process is intended to be brought to the point desired. As the fermentative process proceeds the bulk of the liquor diminishes, and its place must be supplied from time to time by the superfluous portion of must made for the purpose, so as to keep the liquor always near the bung-hole. When the fermentation has subsided a little, the bung may be driven in, taking care, however, to leave a small hole open by its side, which may be stopped with a peg, and opened occasionally to give vent to any air that may be generated.

When the wine has arrived at the desired point of sweetness, &c. it must be racked and clarified in the manner described in the former part of this article; and these processes must be repeated, and the casks sulphured, if necessary, in order to prevent the fermentative process from proceeding farther. In general, however, one racking in the following December or January will be sufficient, after which it may be kept in the cask for any length of time, or it may be bottled without the usual precautions. A fine serene and cold day should be chosen for these operations. Sometimes the fermentative process will stop before the wine has arrived at the desired point, in which case it may be commonly easily re-excited by raising the temperature, and shaking the cask; or, if these fail, by having recourse to the means formerly described for that purpose.

By attending to these general directions, sweet wines may be made from other fruits, care being taken to increase or diminish the quantity of sugar according to the natural sweetness of the fruit employed.

The second general description of wines comprehends the *brisk* or *sparkling* wines; which may be, at the same time, either *sweet* or comparatively *dry*. Our readers will recollect the methods adopted in Champagne, and other countries where they manufacture sparkling wines from the grape, and which are described in the former part of this article. Now these principles are to be held in view in the manufacture of artificial wines intended to possess similar properties. The fruits most generally employed for forming wines of this description, are the immature gooseberry and currant; sometimes also immature grapes, and even vine leaves are made use of for a similar purpose, but grapes are doubtless preferable when they can be procured. Wines of this description are more difficult to be made than the last, at least they require much more care. If gooseberries are employed, they must be gathered when they have nearly attained their full growth, but before they have shewn the least tendency to ripen. The variety of gooseberry is perhaps indifferent, but it will be advisable to avoid the use of those, which in their ripe state have the highest flavour. Dr. Macculloch recommends the *green bath* as among the best. Those which are unsound, as well as the remains of the blossom and footstalk, should be carefully removed. Forty pounds of this fruit, thirty pounds of fine white sugar, and about six ounces of tartar, are sufficient for making ten gallons of wine. All the preliminary processes are to be conducted precisely in the same manner as those above-described for making sweet wines. The *must*, however, ought to remain in the fermenting tub for about twenty-four hours, or two days only, when it is to be transferred to the cask, and the processes of *filling up*, &c. managed as before, except that the wooden peg or spile must be permanently tightened as soon as the danger of bursting the cask

has subsided. The wine thus made may commonly remain during the winter in a cool cellar, as it is no longer necessary to excite the fermenting process. To ensure its fineness, however, it is a good practice to draw it towards the end of December into a fresh cask, so as to separate the lees; and if at this time it should prove too sweet, instead of decanting, it will be better to stir up the lees so as to renew the fermenting process, taking care also to increase the temperature at the same time. At whatever time the wine has been decanted, it is to be fined with isinglass in the usual manner. Sometimes it will be necessary to decant it a second and even a third time into a fresh cask. All these operations should take place, as formerly mentioned, in dry cool weather, and the wine must, at any rate, be finally bottled in March. If immature currants be employed, which are perhaps upon the whole preferable to gooseberries, the same proportion of fruit, sugar, and tartar, and the same modes of management, may be had recourse to; care being taken to separate carefully the stalks of the currants. If grapes be used for the purpose, they may be safely taken of different degrees of ripeness, nor is it necessary to attend to the selection of any particular variety. The same proportions of fruit and sugar will be proper as when gooseberries and currants are employed, but the tartar must be omitted. The husks also may be permitted to ferment with the liquor in the vat. The subsequent management is to be precisely the same as that described above. An excellent wine of the present description may be made from the leaves and tendrils of the vine. About forty pounds of these, and twenty-five or thirty pounds of sugar, will be sufficient for ten gallons of wine. To prepare it, seven or eight gallons of boiling water are to be poured upon the leaves in a tub, and permitted to remain for twenty-four hours. The liquor being poured off, the leaves must be strongly pressed, and subsequently washed with another gallon of water. The sugar and the remainder of the water are then to be added, and the fermentative and all the subsequent processes conducted precisely the same as before. The present class of wines, if the process has been successful, (which is not always the case), is brisk, and precisely similar in their qualities (flavour excepted) to the wines of Champagne, with the strength of the best Sicily.

The third variety of wines is that of which hock, grave, and Rhenish may be taken as examples. In these the saccharine principle is entirely overcome by a complete fermentation, while their future change is prevented by a careful application of the processes laid down for the preservation of wines of this class. Makers of domestic wines have rarely, says Dr. Macculloch, succeeded in imitating these wines. The reasons obviously are, the great disproportion of the sugar to the subsequent fermentation in the first instance; and that want of the after-management, the neglect of which soon consigns these wines to the vinegar cask, if chance should even at first have produced success. In making these wines, the relative proportion of fruit and sugar in common use must be materially altered, and the fermentative process be conducted in a very careful manner. The subsequent processes also of racking, sulphuring, and fining, must be practised with great assiduity, in order to preserve these wines after we have succeeded in making them. Dr. Macculloch states, from his experience, that these wines may be successfully imitated, and that they constitute some of the very best of those which can be made from domestic fruit. The proportion of fruit (generally of immature fruit) to the sugar, in the manufacturing of sweet wines, must be the greatest. The bung must remain open, but the fluid within must not be allowed to escape, while, if the fermentation proceed

WINE.

ceeds languidly, it must be accelerated by heat and agitation. If, when it is finished, the wine continues too sweet, it may be bunged down till the spring without racking or fining, when the fermentation must again be renewed. The renewal of the fermentation may also be effected by adding some fresh juice of the same fruit. At whatever time, and under whatever of these processes, it has become *dry*, it is to be carefully fined and racked into a sulphured cask, and bottled, after being once more carefully fined.

The fourth and last class of wines consists of those which are both dry in their quality, and strong in their nature; such are, Madeira, sherry, &c.; the theory of these, from what has been said, will be sufficiently apparent. With due attention to the fermentative process, such wines may be made of the requisite degree of strength without brandy. By means of this, however, if managed as formerly directed, the operator has it always in his power to produce wines of any required degree of strength.

We need not here repeat the methods of imparting different flavours to domestic wines, or of correcting their faults, since they differ in no respect from those recommended to be adopted in the manufacture of wines from grapes, to which therefore we refer.

The following general remarks upon the fabrication of domestic wines, will not perhaps prove uninteresting to our readers.

The great radical defect in the manufacture of domestic wines, is using too small a proportion of fruit compared with the sugar employed. It is this circumstance chiefly which renders the fermentative process incomplete, and thus imparts that sweet and mawkish taste to our domestic wines, which renders them intolerable to many people, and even to all, perhaps, without the addition of brandy. The proportions of fruit and sugar given above may be considered as mean standards, which may be varied either way, according to circumstances and the nature of the wine intended to be produced. A very superior class of fruit wines may be manufactured by using the juices of our different fruits, either alone or very slightly diluted with water.

We mentioned that some fruits, and especially the black currant, were much improved by boiling. For this purpose, it will be sufficient that the fruit be simply brought to the boiling point before using it, the water in the vessel being so managed as to avoid any risk in burning. The black currant thus treated, and subsequently managed upon the principles we have endeavoured to lay down, is capable of making a wine very nearly resembling some of the best sweet Cape wines.

The fermentative process being rendered tardy and incomplete, by the improper adjustment of the sugar to the fruit, is frequently endeavoured to be excited by *yeast*: nothing can be more injudicious than this. *Yeast* invariably spoils wines, by imparting to them a flavour that nothing will ever overcome. The only ferment to be employed in wine-making, is that furnished by nature; and when this is defective, as is sometimes the case in our domestic fruits, the ferment of the grape must be supplied artificially. This may be done by introducing a certain proportion of *crude tartar*, the dose of which may vary from one to six *per cent.* without materially affecting the wine, as a great proportion of what escapes decomposition will be subsequently deposited. All fruits, except the grape, will require more or less of *tartar*.

The last circumstance we shall notice is the introduction of *brandy*, or other spirit, into domestic wines. As commonly manufactured, they often require, as we have just stated, this addition to render them tolerable. We trust,

however, that from the attention that has been lately paid to the subject of artificial wines, the modes of manufacturing them will be better understood, and that this will no longer be the case. Fine wines are invariably spoiled by the addition of ardent spirit, which seems to have the effect of slowly decomposing them, and thus of destroying that delicate, lively, and brisk flavour, so eminently possessed by all natural wines. Hence it is seldom or never used in wine countries; or rather it is confined to the manufacture of those wines destined for this country, where only this barbarous practice is tolerated. We again repeat, that if the fruit and sugar be duly adjusted to one another, and the fermentative process be properly managed, an infinitely better wine will be produced without the use of brandy, than can ever be produced with it.

General Chemical Properties and Composition of Wines.—The juice of the grape, as we formerly mentioned, consists of a large proportion of water, of certain proportions of the saccharine and fermentative principles, of various acids, especially the tartaric, and some ill-defined extractive principles. These were stated during the fermentative process to undergo different remarkable changes, one of the most important of which is the conversion of the saccharine principle into alcohol. The nature of the other changes are not so well understood, nor does the little we know at present of the composition of wines throw any very satisfactory light upon the subject. One principle indeed, *viz.* the fermentative principle, does not exist in perfect wines, and therefore must be decomposed or separated during the process of fermentation. The principles formed in wines may perhaps be arranged under the four following heads: 1. *Acids*; 2. *Extractive and colouring matters*; 3. *Essential oils*; and 4. *Alcohol*. Water is not mentioned, because it forms the basis of all potable fluids, and consequently of wines.

1. *Acids.*—All acids have the property of reddening turnsole or litmus papers, and therefore contain more or less of a free acid. The acids found in wines are, the tartaric, the malic, the citric, the carbonic, and occasionally the acetic.

The tartaric acid, in combination with potash, or *tartar*, as it is usually termed, exists in great abundance in the juice of grapes, as formerly stated, and appears to be one of its most important ingredients. A large proportion of this tartar is doubtless decomposed during the fermentative processes, and a considerable quantity of what remains is subsequently deposited in the casks or vessels in which the wine is kept, constituting what is termed the *crust*. It appears probable, however, that the whole is not separated, and consequently, as Dr. Thomson justly remarks, that wines are never entirely destitute of tartar. Satisfactory experiments, however, upon an extensive scale, are at present wanting upon this part of the subject. The malic acid, according to the experiments of Chaptal, exists in the greater number of wines, if not in all, and that in much greater proportion than any other acid. If this be really the case, it is probably, in part at least, a product of fermentation, for the juice of grapes appears to contain very little of this acid. Traces of the citric acid were found by Chaptal to exist in some wines. This acid also exists in the juice of the grape, but in small quantity. All wines that have the property of effervescing, or sparkling, when poured from the bottle into a glass, contain carbonic acid. Champagne, for example, owes its characteristic properties to this acid. Sparkling wines are usually weak, and contain less alcohol than usual, for reasons that have been already explained. The acetic acid is not an essential ingredient of wine, nor in fact ought it ever to exist in it. If

WINE.

the fermentation, however, be permitted to go too far, this acid will be formed, and hence it occasionally occurs in inferior wines.

2. *Extractive and colouring Matters.*—These ill-defined substances exist more or less in all wines. Their properties, however, are not well ascertained, nor are they probably uniformly the same in every instance. They have a tendency to separate spontaneously, and along with the tartar form what is termed the *crust*; hence, as wines become older, from their containing less of these matters, they usually become paler. These extractive matters may be also separated artificially by means of animal charcoal, the subacetate of lead, and even partially in some instances by lime-water, or the heat of the sun. The colouring matter, as we formerly noticed, is not derived from the juice of the grape, but from its husk.

3. *Essential Oils.*—Wines, though essentially the same in their general composition, are distinguished from one another principally by their flavour and odour, no less than by the proportion of alcohol they may contain. Now their sensible properties evidently depend upon some volatile and fugacious principle, which has been considered to be analogous to an essential oil. This principle is sometimes derived immediately from the fruit, as, for example, in the wines made from the Frontignac and Muscat grape. At other times, it

is the product of fermentation. Thus the finer flavours of claret, hermitage, and Burgundy, bear no resemblance to those of the grapes, from whence they are formed. Very often, as before stated, the principles of odour and flavour are communicated to wines artificially, by the introduction of foreign ingredients, as orris-root, grape, and elder-flowers, mignonette, &c. The menstruum of this volatile principle is doubtless, in most instances, the alcohol contained in wines; but its quantity is so minute as to be incapable of separation.

4. *Alcohol.*—The characteristic ingredient of wines is alcohol. Indeed, wines may be considered as more or less dilute solutions of alcohol, impregnated with different flavouring substances, and a little acid. There have been great differences of opinion in what state alcohol exists in wines. Some chemists maintain, that alcohol does not exist ready formed in wines, but that its elements only exist in a peculiar state, and that their union is determined, and consequently alcohol formed, by the act of distillation. This opinion was advanced by Fabroni, and seems to have been adopted by some subsequent writers. Mr. Brande, however, has shewn by very decisive experiments, that all wines contain alcohol ready formed, and that this fluid is merely separated during the distillation of these liquors; and his experiments have been since fully confirmed by Gay Lussac.

The following Table, representing the Quantity of Alcohol and other Principles in different Wines, is taken from Dr. Thomson's Chemistry, though it was compiled originally by Neumann. The results are not absolutely to be relied upon, as the state of chemical Knowledge, at the time Neumann wrote, was very imperfect.

24. White hermitage	17.43	On the Uses of Wine in a Dietetic and Medicinal Point of View.—Mankind in every stage of civilization and society betray a propensity for fermented liquors. This indeed is so strongly marked, that some have been induced to consider it as the result of an instinctive faculty, and consequently have been led to suppose that fermented liquors are the pro- per and natural drink of the human race. Others, on the contrary, have contended that fermented liquors are of no real use to mankind, and are often even productive of much positive

Ditto	16.32		
Ditto Lafite	14.08		

positive evid, and hence have arrived at a conclusion diametrically opposite to the former. It is difficult to decide between these opinions. We confess, however, that we do not think it necessary, on the one hand, to have recourse to the supposition of an instinctive faculty to account for wine-drinking; nor, on the other, do we believe that the moderate use of natural wines is productive of any bad effects. The propensity for strong drinks seems explicable upon the general principle that all animals feel a pleasure in *living faster*, or, as it were, crowding a greater portion of existence into a shorter space than natural; an effect in some degree produced by the exciting effects of such liquors. As to the bad effects too frequently produced by fermented liquors, they may, in almost every instance, be fairly traced to the badness of their quality, or to an excess in quantity.

While, however, we do not object to the moderate use of what providence has so liberally bestowed upon us, no one can object more strongly than ourselves to its abuse. The melancholy effects of habitual intoxication are too well known to require particular description here. Severely do the victims of this degrading propensity suffer in mind, body, and fortune; nor are their sufferings confined to themselves, but entailed upon their ill-fated posterity. For proofs of these positions, we refer our readers to the articles GOUT, CALCULUS, APOPLEXY, EPILEPSY, INSANITY, &c. &c. in this work, where they will find these and other diseases justly ranked among the most painful and distressing to which humanity is liable, frequently ascribed to habitual intemperance as their cause.

But putting out of the question these effects of drunkenness, what a horrible picture of moral depravity does it present for a man to sit down deliberately, day after day, with the professed object of annihilating his intellectual faculties, and thus degrading himself below the vilest of the brute creation! And even supposing he has arrived at the *enviable point* of being able to swallow two or three bottles without losing his senses, and that this quantity has become necessary to his comfort, nay even perhaps to his very existence, to what a wretched state of dependence has he reduced his bloated carcase; what a tax is such a being upon society, who, to prolong a loathsome existence, is obliged to consume daily in an unnecessary superfluity more than is sufficient to support a whole family for a week! See DRUNKENNESS.

With respect to the operation of different wines upon the animal economy, they vary exceedingly according to their properties. New wines in general are unwholesome, and often prove purgative. Sweet wines are upon the whole perhaps the most wholesome, and, where the taste has not been previously vitiated, doubtless the most agreeable. Weak and acid wines are very apt to disagree with the stomach, especially when that organ has been accustomed to stronger wines. Hence an occasional debauch with such wines is notorious for inducing a fit of the gout, especially in this country, where the usual wines are immoderately strong. The same is true also, though perhaps in a somewhat less degree, with the effervescing wines. Red wines, in general, are of a more astringent and tonic nature than white wines, and commonly contain more spirit. There are, however, many exceptions to this rule.

It will be seen by consulting the above table, that port, Madeira, and sherry, the three wines in most common use in this country, contain from one-fourth to one-fifth of their bulk of alcohol. A person, therefore, who takes his bottle of wine every day, will thus take nearly half a pint of alcohol, or almost a pint of pure brandy! This at first sight will appear almost incredible, especially as the same person would not perhaps be able to take a similar quantity

of ardent spirit, either diluted with water, or in any other way. Some have concluded from this circumstance that the above experiments are not to be relied upon; but from the manner in which they were conducted there is no reason to doubt their general accuracy; the fact therefore remains to be explained. The most probable explanation is, that the alcohol in the wine is in some state of combination, which prevents its immediate action upon the stomach, and thus renders it liable to be digested or altered in its properties before it can exert its specific effects. The peculiar nature, however, of this state of combination is at present unknown. What renders this opinion the more probable is, that some bad wines, and especially domestic wines, which are often little better than mere mixtures of brandy and water, exert much more effect upon the animal economy than fine old wines, though they may not contain nearly so much spirit.

With respect to the medicinal uses of fermented liquors, when cordials are required, wines are by far the most efficient of the whole tribe, and of these *port wine* is perhaps the best. For full information on this head, we refer our readers to the articles FEVER, GANGRENE, and *Analogous Diseases of DEBILITY*. See Chaptal's excellent Essay on the Manufacture of Wines, *Annales de Chimie*, vol. xxxvi. and xxxvii. Dr. Macculloch's Essay on Wine-making. Mr. Brande's Essays in *Phil. Trans.* for 1811 and 1813, &c.

For the distillation of wines, see DISTILLATION.

WINE being a liquor mostly of foreign produce, the different names, forms, kinds, distinctions, &c. of it are borrowed from the countries where it is produced, particularly France.

Wine, in France, is distinguished, from the several degrees and steps of its preparation, into

Merre-goutte, mother-drop; which is the virgin wine, or that which runs of itself out of a tap of the vat, in which the grapes are laid, before the vintager enters to tread, or stamp, the grapes.

Must, *surmust*, or *stum*, is the wine, or liquor, in the vat, after the grapes have been trodden, or stamped.

Pressed Wine, *Vin de Pressurage*, is that squeezed with a press out of the grapes, when half-bruised by the treading. The husks left of the grapes are called *rape*, *muck*, or *marc*; by throwing water upon which, and pressing them afresh, they make a liquor for servants' use, answerable to our cyder-kin, and called *boisson*; which is also of some use in medicine, for the cure of disorders occasioned by viscid humours.

Sweet Wine, *Vin doux*, is that which has not yet worked, or fermented. This is turbid, and has an agreeable and very saccharine taste. It is very laxative, when drunk too freely, or by persons disposed to diarrhoeas, it is apt to occasion these disorders. Its consistence is somewhat less fluid than that of water, and it becomes almost of a pitchy thickness when dried.

Bouru, that which has been prevented working, by casting in cold water.

Cuve, or *worked wine*, that which has been let work in the vat, to give it a colour.

Cuit, or *boiled wine*, that which has had a boiling before it worked; and which, by these means, still retains its native sweetness.

Passe, or *strained wine*, a sort of raisin-wine, made by sleeping dry grapes in water, and letting it ferment of itself.

Wines are also distinguished with regard to their colour, into *white wine*, *red wine*, *claret wine*, *pale wine*, *rose* or *black*

WINE.

black wine. And, with regard to their country, or the soil which produces them, into *French wines, Spanish wines, Rhenish wines, Hungarian wines, Greek wines, Canary wines, &c.* And, more particularly, into *Port wine, Madeira wine, Burgundy wine, Champagne wine, Falernian wine, Tokay wine, Schiras or Sberaz wine, &c.*

Wines, again, are distinguished, with regard to their quality, into *sweet wines, rough or dry wines, and rich or luscious wines, vins de liqueur*; of which last some are exceedingly sweet, others sweet and poignant; and all chiefly used by way of a dram after meals, &c.

Such are French, *Frontignac, Madeira, the Canary, the Hungary, Tokay*, the Italian *Montefiascone*, the Persian *Schiras*, the *Malmsey wines* of Candia, Chio, Lesbos, Tenedos, and other islands of the Archipelago, which anciently belonged to the Greeks, but now to the Turks. These are sometimes called *Greek wines*, and sometimes *Turkey wines*.

The chief wines drank in Europe are as follow. 1. The Madeira island, and Palma, one of the Canaries, afford two kinds: the first called *Madeira sec*, the latter, which is the richest and best of the two, *Canary or Palm sec*. The name *sec* (corruptly written *sack*) signifies dry; those wines being made from half-dried grapes. There is another sort of *sec wine*, prepared about Xeres, in Spain, and hence called, according to our orthography, *Sheris, or Sherry*. 2. The wines of Candia and Greece are of common use in Italy. *Malmsey* was formerly the produce of those parts only, but is now brought chiefly from Spain: it is a sweet wine, of a golden or brownish-yellow colour, and to this is applied an Italian proverb, signifying, *Manna to the mouth, and balsam to the brain*. Almost all the wines used in the Venetian territories come from Greece and the Morea. 3. Italy produces the *vino Greco*, which is a gold-coloured unctuous wine, of a pungent sweetness, the growth of mount Vesuvius, but much sophisticated by the Neapolitans. In the neighbourhood of mount Vesuvius is made the *Mangiaguerra* wine, and a thick, blackish one, called *Verracia*; and at the foot of the hill the delicious *vino vergine*. The kingdom of Naples affords the *Campania or Pauslippo, Muscatel, Salernitan*, and other excellent wines, and also the *Chiarello*, much drank at Rome. But the principal is the red, fat, sweet, and grateful poignant one, called *Lachryma Christi*. 4. The Ecclesiastical State produces the bright, pleasant *Albano*, and the sweet *Montefiascone*, a yellowish not very strong wine, resembling good Florence, &c. 5. In Tuscany are the excellent white and red *Florence*; the celebrated hot, strong, red wine, *de Monte Pulciano*, &c. 6. In Lombardy, the *Modense* and *Monterrat* are tolerable; between Nizza and Savona is produced an incomparable *Muscadine*. 7. Piedmont and part of Savoy have excellent light wines. 8. The Sicilian, Sardinian, and Corsican wines are also good. 9. Most of the Spanish wines are composed of fermented or half-fermented wine mixed with inspissated must, and variously manufactured, or of an infusion of dry grapes in weak must. Of these wines, there are a few in Germany, as the *Alicant*, which is a thick, strong, very sweet, and almost nauseous wine, *Sherry, Spanish, Malmsey*, &c. 10. In Portugal there is plenty of red *Port*, which is much drank in England. The best *Vino tinto*, a blackish-red wine used by the coopers for colouring other wines, is said to be the produce of Portugal. This kingdom also deals largely in *Madeira*. 11. In France there is a great variety of wines; of which the strong, sweet, full-bodied, spirituous ones, are called *Vins de liqueur*. Languedoc and Provence afford the sweetest wines, and the same provinces, with Champagne

and Burgundy, the strongest; the wines of the northern parts, as Picardy and Bourdeaux, are the worst, and those about the middle of the kingdom, as Paris and Orleans, of a middling kind. The most celebrated of the French wines are, *Champagne, Burgundy, Vin de beaune*, or partridge-eye, *Frontinac, Hermitage*, &c. 12. In Switzerland, the best wines are, the *Neufchatel, Valteline, Lacote, and Reiff*: the *Valteline* straw-wine, so called from the grapes being laid for some time upon straw before they are pressed, is particularly celebrated. 13. The dry-grape wines of the Upper Hungary are in general excellent, and much superior to those of the Lower. (See TOKAY.) 14. Among the German wines, those of *Tyrol* are very delicate, but do not keep. 15. Of Austrian wines, those of *Kloster-Newburg* and *Brosenberg* are deemed the best: and there are also good wines in other parts of the Imperial dominions. 16. In the Palatinate, the best wine is that of *Worms*, especially the sort called *Women's Milk*. 17. Among the more esteemed German wines may be reckoned also *Rhenish, Mayne, Moselle, Neckar*, and *Elsass*: a certain writer calls the *Rhenish* made in Hockheim (Hock) the prince of the wines of Germany.

Wine is also variously denominated, according to its state, circumstances, qualities, &c. *e. g.*

Natural Wine, is such as comes from the grape, without farther mixture, or sophistication.

Brewed Wine, or Adulterated, is that in which some drug is added, to give it strength, fineness, flavour, briskness, sweetness, or some other quality which is wanted.

Pricked Wine, or Eager, is that turned sourish.

An easy method of recovering pricked wines may be learned from the following experiment:—Take a bottle of red port that is pricked, add to it half an ounce of tartarized spirit of wine; shake the liquor well together, and set it by for a few days, and it will be found very remarkably altered for the better.

This experiment depends upon the useful doctrine of acids and alkalies. All perfect wines have naturally some acidity, and when this acidity prevails too much, the wine is said to be pricked, which is truly a state of the wine tending to vinegar: but the introduction of a fine alkaline salt, such as that of tartar, imbibed by spirit of wine, has a direct power of taking off the acidity, and the spirit of wine also contributes to this, as a great preservative in general of wines. If this operation be dexterously performed, pricked wines may be absolutely recovered by it, and remain saleable for some time: and the same method may be used to malt-liquors just turned sour. Shaw's Lectures, p. 214.

Flat Wine, is that fallen weak and vapid, for want of being drank in time.

Sulphured Wine, is that put in casks in which sulphur has been burnt; in order to fit it for keeping, or for carriage by sea.

Colour, is a thick wine, of a very deep colour, serving to dye the wines that are too pale, &c. as the black wine in use among vintners. See WINE *supra*.

The method of converting white wines into red, so much practised by the modern wine-coopers, is this: put four ounces of turnsole rags into an earthen vessel, and pour upon them a pint of boiling water; cover the vessel close, and leave it to cool; strain off the liquor, which will be of a fine deep red, inclining to purple. A small proportion of this colours a large quantity of wine. This tincture might be either made in brandy, or mixed with it, or else made into a syrup, with sugar for keeping. A common way with the wine-coopers is to infuse the rags cold in wine for a night or more, and then wring them out with their hands;

but

but the inconveniency of this method is, that it gives the wine a disagreeable taste, or what is commonly called the taste of the rag, whence the wines, thus coloured, usually pass among judges, for pressed wines, which have all this taste from the canvas rags in which the lees are pressed.

The way of extracting this tincture, as here directed, is not attended with this inconveniency; but it loads the wine with water; and if made into a syrup, or mixed in brandy, it would load the wine with things not wanted, since the colour alone is required. Hence the colouring of wines has always its inconveniences. In those countries which do not afford the tinging grape, which affords a blood-red juice, wherewith the wines of France are often stained, in defect of this, the juice of elderberries is used, and sometimes log-wood is used at Oporto.

The colour, afforded by the method here proposed, gives wines the tinge of the Bourdeaux red, not the Port; whence the foreign coopers are often distressed for want of a proper colouring for red wines in bad years. This might perhaps be supplied by an extract made by boiling stick-lack in water. The skins of tinged grapes might also be used, and the matter of the turnsole procured in a solid form, not imbibed in rags. Shaw's Lectures, p. 211.

Chip Wine, is that poured on chips of beech-wood, to fine or soften it.

Rape Wine, is that put in a cask half-full of fresh grapes picked for the purpose, to recover the strength, briskness, &c. which it had lost by keeping, &c.

Burnt Wine, is that boiled up with sugar, and sometimes with a little spice.

There is also a sort of Malmsey wine made by boiling of muscadine.

Wines, Condensing of, a phrase used by Stahl, and some other writers, to express what is more usually called the concentrating of them, that is, the freeing of them from the superfluous humidity which they contain, and by these means rendering them more rich and noble, freeing them from their tasteless part, reducing them to a smaller bulk, and thus making them fitter for transportation, and finally rendering them more durable in their perfect state, and much less subject to the various accidents that make them decay. See CONCENTRATION.

Various methods have been attempted for the effecting of this, as by means of heat and evaporation, or by percolation, &c. and great objections found in the way of all of them, except the latest, brought into use by Stahl, and since recommended greatly to the world by Dr. Shaw in his Chemical Essays.

If any kind of wine, but particularly such as has never been adulterated, be, in a sufficient quantity, as that of a gallon or more, exposed to a sufficient degree of cold in frosty weather, or be put in any place where ice continues all the year, as in our ice-houses, and there suffered to freeze, the superfluous water that was originally contained in the wine will be frozen into ice, and will leave the proper and truly-essential part of the wine unfrozen, unless the degree of cold should be very intense, or the wine but weak and poor. This is the principle on which Stahl founds his whole system of condensing wine by cold.

When the frost is moderate, the experiment has no difficulty, because not above a third or fourth part of the superfluous water will be frozen in a whole night; but if the cold be very intense, the best way is, at the end of a few hours, when a tolerable quantity of ice is formed, to pour out the remaining fluid liquor and set it in another vessel to freeze again by itself.

If the vessel, that thus by degrees receives the several

parcels of the condensed wine, be suffered to stand in the cold freezing place where the operation is performed, the quantity lying thin in the pouring out, or otherwise, will be very apt to freeze anew; and if it be set in a warm place, some of this aqueous part thaws again, and so weakens the rest. The condensed wine, therefore, should be emptied in some place of moderate degree as to cold or heat, where neither the ice may dissolve, nor the vinous substance mixed among it be congealed. But the best expedient of all is to perform the operation with a large quantity of wine, or that of several gallons, where the utmost exactness, or the danger of a trifling waste, needs not be regarded.

If the wine now once concentrated should, by a long continuance in the freezing cold, be again congealed to the utmost (unless the cold were very severe indeed), and then again be drained from its ice, there, soon after this, falls to the bottom of the vessel a pure white powder or tartar, and even the icy part afterwards deposits also a little of the same substance after thawing; and after standing two or three days, there is always more and more of this tartar precipitated, and that constantly the more in proportion as the wine was more austere, or less adulterated with sugar, brandy, or the like; for these things contain no tartar.

The ice of the second operation on a quantity of wine differs in nothing from that of the first, provided only that the wine was poured clear off from it, before the ice is set to melt, by which means it dissolves into a clear phlegm. This shews the excellency of the operation; as it loses not its efficacy upon repetition, but brings away mere water as well at last as at first, without robbing the wine of any of its genuine or truly valuable parts. The remaining unfrozen liquor is a real concentrated wine, as appears by its colour, consistence, taste, and smell, and is actually become a nobler and richer wine than could have been procured without such a contrivance.

This operation, though it be perfect in regard to wine, yet does not succeed so well in regard to the malt-liquors. The experiment has been fairly tried by Stahl on a gallon of strong malt-drink, and the success was as follows:—The ice separated in the first operation, when thawed by heat, resolved into a liquor of the colour and taste of small-beer; and the second concentration afforded an ice of much the same kind, which might have passed for ordinary small-beer, but for a flashy watery taste that manifestly predominated in it. The liquor unfrozen was but a pint and a half by measure, but it was extremely rich and thick, and seemed very strong and spirituous, and perfectly aromatic, or highly flavoured. The consistence was something like that of a thin syrup, and it had a pleasing softness that sheathed the acrimony of the spirit, and covered the bitter taste of the hop.

The mucilaginous nature, which is predominant in all malt-liquors, occasions a great inaccuracy in this experiment, as not suffering the water to run clear, or be separated from the richer tincture of the malt, nor letting the condensed liquor be obtained clean from the ice; but as the loss occasioned by this is not great, and the liquor is much cheaper than wine, if this should ever come into use in the large way, the thawed liquor of the ice might be used again in a new brewing, and so the loss of that part of the strength which was carried away by the freezing be recovered.

Wines in general may by this method be reduced to any degree of vinosity or perfection. Thus, for example, if a wine of a moderate strength hath a third part of its water taken away, in form of ice, by congelation, the remaining part will thereby be doubled in strength and goodness: for if we allow, in the better sorts of wine, that one-third part, which

which is near the truth, is truly good or vinous, and two-third parts are nothing but water, one-third part of the good wine being blended among the two-third parts of water, of no strength or value; it follows, that if one of these third parts of water be taken away, and all the wine left, that which was before but one-third wine, is now one-half wine, no way reduced in its strength, and therefore the whole must be stronger in that proportion.

But if this operation of congelation be carried to the utmost, and be practised on a large quantity of wine, and with a very intense cold, and the ice taken away several times, and the wine, thus freed from a part of its water, again and again exposed, it will be found that good wines will be reduced to one-sixth part of their original quantity: and the vintner will easily find out the use of this remaining sixth part, which is a true quintessence of wine, and will be of the utmost benefit, by mixing it in small quantities with poor and low-flavoured wines, to meliorate and improve them; and even to convert the low-flavoured and least valuable ones into those very wines from which this condensed part was procured.

This method is not practicable to advantage in the wine countries alone. Dr. Shaw assures us, that he has himself experimented it here, and with the use of proper freezing mixtures has reduced wines in England to a much smaller quantity, in proportion to the whole, than in the strongest of Stahl's experiments. It is evident, that by how much the quantity is smaller, by so much it is richer and stronger, provided that the operation has been properly performed. The doctor assures us, the noble essence or rob, thus prepared, is capable of working almost miracles, by turning water into wine, and the like; but that, in order to its succeeding well, there requires great care in the operator, when the congelation is repeated the last times. Shaw's Chem. Ess. Stahl's Schematism. de Concentrat. Vin.

WINE, *Clarification of.* See CLARIFICATION, and WINE *supra.*

WINE, *Colouring of.* See WINE Colour, and WINE *supra.*

WINE, *Fining of.* See FINING, and WINE *supra.*

This operation is practised in Germany in the following manner: they have in some vaults three or four stoves, which they heat very hot: others make fires almost before every vat; by which means the must is made to ferment with great vehemence. When the ebullition, fermentation, and working cease, they let the wine stand, and then rack it. This fining is only used in cold years, when the wine happens to be green.

WINE, *Forcing of.* See FORCING.

WINE, *Domestic.* See WINE *supra.*

In the Museum Rusticum we have the following directions for making raisin wine: put thirty gallons of soft water into a vessel at least one-third bigger than sufficient to contain that quantity; and add to it one hundred weight of Malaga raisins, grossly picked from their stalks. Mix the whole well together, and cover it partly with a linen cloth. When it has stood a little while in a warm place, it will begin to ferment, and must be well stirred about twice in twenty-four hours, for twelve or fourteen days. When the sweetness is nearly gone off, and the fermentation much abated, which will be perceived by the subsiding and rest of the raisins, strain off the fluid, pressing it, first by the hand, and afterwards by a press, out of the raisins. Let this liquor be put into a sound wine-cask, well dried and warmed, adding eight pounds of Lisbon sugar, and a little yeast, and reserving part of the liquor to be added from time to time, as the decline of the fermentation will give

room. In this state, the liquor must remain for a month, with the bung-hole open; and having filled the vessel with the reserved liquor, let it be closely stopped, and kept for a year or longer, and then bottled off. At the end of a year and a half it may be drank, but will improve for four or five years.

Some saving may be made in the expence, by diminishing the quantity of raisins, and increasing that of the sugar, in the proportion of four pounds of raisins for one of sugar; or by diminishing the proportion of both raisins and sugar, and adding clean malt-spirits, when the bung of the cask is closed up. Any other large raisins may be used, as well as the Malaga; but the thinner the skins and the sweeter the pulp, the stronger will be the wine.

If this wine be perfectly fermented, and kept a long time, so that no sweetness remain, it will resemble Madeira.

An artificial Frontignac may be made of this wine, in which the proportion of sugar or of malt-spirits to the raisins is large, and the whole body weaker: the muscadel flavour being communicated by an infusion of the flowers of meadow-sweet. In the making of this artificial Frontignac, the ferment should be stopped, by closing the cask and adding the spirit, while a considerable degree of sweetness remains, and the wine may be drank after it has been a little while in the bottles.

Cyprus wine may be imitated by the same means, using three or four pounds more of sugar than the quantity above prescribed, and stopping the fermentation while a considerable degree of sweetness remains.

Artificial Mountain may be made by preserving a small degree of sweetness, giving the nut-like flavour, and keeping the best kind of the above wine to a due age. The flavour may be obtained by the infusion of the Florentine orris-root, powdered, with a very small proportion of orange and lemon peel; and the wine may be rendered more dry or sweet, by continuing the fermentation for a greater or less time, and adding a corresponding proportion of clean malt-spirits, when the fermentation is stopped sooner. The adding of some of the stony seeds of the raisins well bruised will give the nut-like flavour; and the putting in a part of the stalks will add a sharpness, found generally in this kind of wine.

The racy taste of Canary, commonly called sack, may be counterfeited by the addition of a proper quantity of the juice of white currant-berries to the wine, made with a large proportion of sugar to the raisins, and left very sweet in the fermentation. But it is said that a spirit, distilled from the leaves of clary and clean malt-spirits, put to the wine, will give it a very strong resemblance of sack. It is said also, that the juice of the bramble-berries, added to the mixture of the wine, before the fermentation, will give both the colour and flavour of claret: but in this case the quantity of raisins should be considerably diminished, and that of the sugar increased, as the fermentation must be continued till the sweetness be wholly destroyed.

Wines of this kind should be kept at least a year before they are drank. See SWEETS.

WINE, *Extemporaneous.* A hundred weight of good treacle will produce, according to the art of the distiller, from four to seven gallons of pure alcohol; that is, from eight to fourteen gallons of the common-proof melasses spirit. The still-bottoms have many uses. The distillers scald and recover their musty casks with them, and they may be used for all those purposes of cleansing where argol is required. Mr. Boyle's acid spirit of wine, or a spirit very like it, may also be procured from them, and a matter analogous

analogous to that Becher calls the *media substantia vini*. This liquor gives a durable extemporaneous wine.

WINE, *Stooming of*. See STOOMING.

WINES, *Low*, in *Distillation*, a term applied to the liquor which first comes over, when the *wash* is subjected to distillation, and which is concentrated by a second operation. See DISTILLATION.

WINES, *Medicinal* or *Medicated*, in *Pharmacy*, a term applied to those preparations, consisting of wine holding different active ingredients in solution. They were formerly very numerous, but at present their number is very limited. See VINUM, under which article those at present in use are described.

WINE, *Lees of*, are the impurities of it, or the thick sediment remaining at the bottom of the casks, when the wine is drawn out.

The distillation of wine-lees into spirit is conducted very much in the same manner with that of the malt-wash, when distilled with the mealy part in it: the principal difference is on this account, that the oil of the malt being very nauseous and disagreeable, the utmost care is to be used to keep it back in all the processes of primary distillation, and of rectification; whereas, on the other hand, the oil of the wine-lees being a very agreeable and pleasant one, as much care as possible is to be taken to bring it over with the spirit. Glauber has written a peculiar treatise on this subject, in which, without touching upon the most advantageous production of all, he has proved the work to be so very profitable, that the whole usually passes for one of his wild flights, rather than a solid business.

The method of distilling a liquid ley for its spirit is a thing universally known; but the advantageous thing, on this basis, is the distilling of a dry ley pressed and preserved, and the managing of the business in such a manner as at first or last to procure and separate all its valuable parts. The solid ley, here mentioned, is that usually sold to the hatters in England, and is the same thing that in France and other wine countries the vinegar-makers dispose of in cakes, after they have pressed out all the wine, and which was afterwards burnt, and makes what Lemery and others call *cineres clavellati*; and the English *gravelled ashes*, a fixed alkaline salt-like potash.

This ley, when used for distilling, should be that of the French wines, and either such as is newly pressed, or has been well secured by packing in a close manner in tight casks, with some proper contrivance of dry sand, or the like, to keep its external surface from the contact of the air, which is very apt to corrupt or putrefy it.

If this ley is intended to be kept many months, it will be very proper to secure it by sprinkling the layers as they are packed up with a little brandy. The expence of this is nothing, for the brandy is recovered again in the operation. Shaw.

WINE, *Oil of*, a very precious liquid, kept as a secret in the hands of some dealers in spirits, and used to give the brandy flavour to spirits of less price. It is certain that all the spirits we use take their flavour from the essential oil of the substance they are made from; that of malt is very nauseous and offensive, and renders the spirit horribly disagreeable, if not carefully kept back in the distillation of it; that of the grape, on the other hand, is extremely agreeable, and is what gives the delicious flavour to French brandy: this, therefore, is to be carefully brought over among the spirits in distillation.

This is that oil of wine so much celebrated among our distillers, and is for their use made separate, and is of such effect, that half an ounce of it will determine a pure and

clear malt spirit to be French brandy, so as to stand the test of the nicest palate, and all the trials that can be invented, provided the oil and the spirit have both been carefully made.

The manner of making the oil is this: they take some cakes of dry wine-lees, such as are used by our hatters, and dissolving them in six or eight times their weight of water, they distil the liquor with a slow fire, and separate the oil by the separating pot, reserving for this nice use only that which comes over first, the oil that follows being coarser, and more resinous. To render this business perfectly successful, there must be several things observed: 1. The ley must be of the right kind, that is, of the same nature with the French brandy proposed to be imitated. 2. The malt-spirit must be extremely pure. 3. The dose of the oil must be very well proportioned. And, 4. The whole must be artificially united into one simple and homogeneous liquor. These cautions all regard only the taste, and besides these, in order to come up to a nice counterfeit, several other particulars must be attended to; such as the colour, proof, tenacity, softness, and the like; so that, in short, the operation has too much nicety in it to be hit off by every ordinary dealer. When this fine oil of wine is procured, it may be mixed into a quintessence, with pure distilled alcohol, or the totally inflammable spirit of wine, to prevent its growing distasteful, rancid, or resinous; and thus it may be long preserved in full possession of its flavour and virtues.

The still-bottoms, or remaining matter after the distillation of this oil, will yield many productions to advantage, particularly tartar, and salt of tartar, as also an empyreumatic oil, and a volatile salt, like that of animals. Some kind of lees afford all these in much greater quantity than others; the lees of Canary and Mountain wines yield very little of them; and, indeed, scarce any tartar or fixed salt at all; but the white French lees of those thin wines that afford the ordinary brandies, yield them all very copiously, inasmuch that sometimes a single hoghead of dry and close-pressed lees will afford, by this process, three gallons of brandy, forty pounds of clean tartar, a large proportion of empyreumatic oil, and volatile salt, beside full four pounds of good salt of tartar. It is not to be expected, however, that every parcel of this ley should yield fully in this proportion. Shaw's Essay on Distillery.

WINE, *Piece of*. See PIECE.

WINE-Press, a machine contrived to squeeze the juice out of grapes, and consisting of several pieces of timber, variously disposed, which compose three bodies of timber-work, closely united to the axis, which serves as a swing, by which it may be moved by the vice. Of these there are different sizes as well as different constructions.

WINE, *Prisage of*. See PRISAGE.

WINE, *Racking of*. See RACK, and WINE *supra*.

WINE, *Spirit of*. See SPIRIT.

WINE-Spirit, a term used by our distillers, and which may seem to mean the same thing with the phrase *spirit of wine*; but they are taken in very different senses in the trade.

Spirit of wine is the name given to the common malt-spirit, when reduced to an alcohol, or totally inflammable state; but the phrase *wine-spirit* is used to express a very clean and fine spirit, of the ordinary proof-strength, and made in England from wines of foreign growth.

The way of producing it is by simple distillation; and it is never rectified any higher than common bubble-proof. The several wines of different natures, yield very different proportions of spirit; but in general the strongest yield one-fourth, the weakest in spirits one-eighth part of proof-spirit;

WINE.

spirit; that is, they contain from a sixteenth to an eighth part of their quantity of pure alcohol.

Wines that are a little four serve not at all the worse for the purposes of the distiller; they rather give a greater vinosity to the produce. This vinosity is a thing of great use in the wine-spirit, whose principal use is to mix with another that is tartarized, or with a malt-spirit, rendered alkaline by the common method of rectification. All the wine-spirits made in England, even those from the French wines, appear very greatly different from the common French brandy; and this has given our distillers a notion that there is some secret art practised in France, for giving the agreeable flavour to that spirit; but this is without foundation.

When we distil Sicilian or Spanish wines, we do not produce Sicilian or Spanish brandies; and the true reason of this is, that the wines which they distil on the spot into brandy, are very different from those which they export as wines.

Those they distil are so poor and thin, that they will not keep many months, nor can possibly bear exportation. If we had in England those poor wines they distil into brandy near Bourdeaux, Cognac, or up the Loire, there is no doubt that the spirit we made from them would be universally allowed to be French brandy. We have proof of this from some of the Scotch distilleries, where they, with no peculiar art, or secret method, procure from some of the poor pricked and damaged wines received here, brandy so nearly resembling that of France; that a good judge will scarcely be able to make the distinction. Wine-spirits and brandies, therefore, are the same thing, only with this difference, that the former is the product of a rich wine, and the latter of a poor one; or, at the utmost, they differ only as our two home products, the cyder-spirit and the crab-spirit, do.

The wine-spirit, distilled in England, is not easy to be had pure and unmixed at our distillers, nor under a price almost equal to that of French brandy; so that if it ever be required out of the trade, it is as well to use the French brandy, which will, in all cases, serve the same purposes, unless where a high flavour or a copious essential oil are required. All other spirits are carefully divested of their oil in the rectifications; but the wine-spirit is coveted only for its oil, and all that can be obtained is preserved in this, its principal use being to give a flavour to a worse spirit, and to cover the taste of a disagreeable oil in it.

When a cask of wine chances to turn sour in private hands, it is worth while to distil it for the spirit. The lees, also, if in any considerable quantity, will yield such a proportion of the same sort of spirit, as to render it worth while; and as the high flavour is not required in this intent, it will be best to draw off the spirit very gently, either by the cold or hot still, and afterwards it may be rectified without any addition, and reduced to the standard-strength of proof. It thus makes a very clean and pleasant spirit, though very different from the brandy from the same country whence the wine came. *Shaw's Essay on Distillery.* See SPIRIT.

WINE, *Philosophic Spirit of*, in the writings of some chemists and physicians, a phrase that often occurs as the name of a liquid prepared from wine, and endued with very remarkable properties.

It is generally supposed that this was the same sort of liquor, which we at this time call by the name of spirit of wine; but this is a very erroneous opinion, and has led many into errors, about the operations in which it was

concerned. It was truly no distilled liquor, but the spirituous parts of wine condensed and concentrated by the freezing of the more aqueous part.

WINE *Vinegar, Method of making of.* See VINEGAR.

WINE, *Laws relating to.*

Wine may be imported only in British-built ships, or vessels of the built of that country of which the wine is the produce, legally navigated; or in ships the built of the country in Europe under the dominion of the sovereign or state in Europe, of which the wine is the produce, or of the usual place of shipping. Penalty, forfeiture of the wine and the ship. 12 Car. II. c. 18. and 27 Geo. III. c. 19.

No other than Rhenish wine may be imported from the Netherlands or Germany, on forfeiture of ship and goods. 13 & 14 Car. II. c. 11. But wine, the produce of Hungary, may come from Hambro'; also wine, the produce of Hungary, the Austrian dominions, or any part of Germany, may come from the Austrian Netherlands, or any place subject to the emperor of Germany or house of Austria. 1 Ann. stat. 1. c. 12. and 22 Geo. III. c. 78.

Wine may not be imported in vessels under sixty tons burthen: wine and vessel forfeited. 24 Geo. III. c. 47. 26 Geo. III. c. 59. and 45 Geo. III. c. 121. Spanish and Portugal wines may not be imported in any cask containing less than a hoghead, except for private use. 18 Geo. III. c. 27. and 25 Geo. III. c. 69. French wine the same; and, except French wine in bottles, from France, Guernsey, Jersey, or Alderney. 18 Geo. III. c. 27. and 27 Geo. III. c. 13. By the 5 Ann. c. 27. a hoghead is to contain 63 gallons, or 231 cubical inches of wine. Wine (*i. e.* not Spanish nor Portugal) may not be imported in flasks, bottles, or casks, containing less than 25 gallons, except of the produce of the dominions of the grand duke of Tuscany, in open flasks, or any part of the Levant, and also wine for private use. 1 Geo. II. stat. 2. c. 17. and 25 Geo. III. c. 69. Wine may be imported in casks containing six dozen reputed quart bottles at the least. 39 & 40 Geo. III. c. 83. 42 Geo. III. c. 44. and 45 Geo. III. c. 121. Five reputed quart bottles deemed a gallon in charging duty. Wine not to be imported unless accompanied by a manifest, attested by the consul at the place of shipment. 26 Geo. III. c. 40. Wine must be entered at the custom-house and excise-office within 20 days after the ship has reported, or it may be sold for the duties, and must be removed from the quays in 10 days. 26 Geo. III. c. 59. and 35 Geo. III. c. 118. Wine landed without payment of duty is forfeited (20 Geo. III. c. 59.); but wine may be warehoused under schedule B, without payment at the time of entry of the duties due on importation, on the importer giving bond to export the same, or pay the duties within 12 months. But duty must be paid when taken out, on any excess or deficiency, from the quantity taken at the time of landing; and no wine to be warehoused in casks less than 45 gallons. 43 Geo. III. c. 132. Wine that has been warehoused may be exported, and wine that has paid duty may be shipped for drawback; but must be packed in the presence of the proper excise-officers, and the casks to be sealed with their official seals, and if they are afterwards damaged or broken, the party offending to forfeit 50*l.* for each cask or package. Due notice to be given in writing of the times of packing and shipping. 26 Geo. III. c. 59. f. 46, 47. The exporter to give bond before shipping that the same shall be exported to the place entered for, and shall not be reloaded or unshipped. To be landed in Great Britain, on forfeiture. 26 Geo. III. c. 59. f. 48.

35 Geo. III. c. 118. Wine may be exported to Douglas, in the Isle of Man, in British vessels of 50 tons, by licence of the commissioners of the customs. 52 Geo. III. c. 140.

All the duties paid upon wine shipped for the actual consumption of officers of the navy on board ship, to be drawn back according to the following proportions. 33 Geo. III. c. 48.

	Tons.
Admiral - - - - -	6
Vice-admiral - - - - -	5
Rear-admiral - - - - -	4
Captain of a first and second rate - - - - -	3
Captain of a third, fourth, and fifth rate - - - - -	2
Captain of every inferior ship - - - - -	1
Lieut. and other officer in commission - - - - -	0½

Officers of marines to be allowed half a ton *per annum*. 53 Geo. III. c. 44. But to be shipped only at the ports of London, Rochester, Dover, Dartmouth, Portsmouth, &c. Officers may remove their stock from one ship to another, and dispose of it to other officers. 38 Geo. III. c. 33.

Dealers in foreign wine to enter their premises at the excise-office, on penalty of 100*l.* for every place not entered, and forfeiture of the wine found therein. 26 Geo. III. c. 59. f. 12. Dealers to have the words 'Dealers in foreign Wines' painted over their doors, on penalty of 50*l.* sect. 15. Retailers to have the word 'Wine' exhibited in some conspicuous part of their premises, on penalty of ten shillings. 30 Geo. II. c. 19. and 32 Geo. II. c. 19. Dealers to take out a licence, to be renewed ten days before the expiration of every year, on penalty of 100*l.*; but not to apply to auctioneers selling wine by auction. 26 Geo. III. c. 59. Retailers of foreign wines, and dealers in sweets or British wines, to take out licences also; and selling them after its expiration, and before renewed, subjects them to 50*l.* penalty. 30 Geo. III. c. 18. Retailers not to sell wine in their houses, unless they have a beer licence granted by the magistrates, on penalty of 20*l.* (See *ALE-HOUSES*.) Officers may enter at any time to take an account of the stock, but if they go in the night they must be attended with a constable. The party refusing them admittance, or obstructing them, forfeits 100*l.* 26 Geo. III. c. 59. f. 17. No wine to be brought into a dealer's possession without a permit, and dealers to mark on a conspicuous part the content of each cask. 26 Geo. III. c. 59. f. 32. Any excess in dealer's stock from the account last taken, after deducting the quantity sold and entered in their books, deemed not to have paid duty, and is forfeited, and double the value. 26 Geo. III. c. 5. f. 59. 27 Geo. III. c. 31. Different kinds of wine and liquors, (cyder, spirits, &c.) to be kept separate. 26 Geo. III. c. 59. 42 Geo. III. c. 93. And no dealer in foreign wine to have any sweets or British wines in his possession. Penalty 10*s.* *per* gallon. 26 Geo. III. Account of wine daily sold to be kept, and no quantity above three gallons to be removed without permit, on forfeiture of the same, and the carriage and horles. 26 Geo. III. c. 59. 42 Geo. III. c. 95. Wine, in possession of persons *not* dealers, may have permits granted for its removal, on proving to the satisfaction of the commissioners of excise, or the collector or supervisor of the district, that the duties have been paid. 26 Geo. III. c. 59. f. 33. Permits not used to be returned to the officer, on penalty of treble the value of the wine. 26 Geo. III. c. 59. f. 37, 38; and persons forging or counterfeiting them to forfeit 500*l.* *Ibid.* sect. 39.

For the laws relating to low wines and domestic wines, see *DISTILLER*, and *SWEETS*.

WINE of Squills. See *SQUILLS*.

WINE-Measure. See *MEASURE*, and *Laws relating to WINE supra*.

WINE-Fly, in *Natural History*, the name of a small black fly, found in empty wine-casks, and about wine-lees, and called by the Latins, *Bibio*.

It is produced of a small red worm, very common in the sediment of wine.

The drippings of wine or beer vessels, the pressings of the wine or cyder press, the pots in which honey has been kept, and in which a little remains sticking to the sides, and turning sour, all afford vast numbers of a small species of worm or maggot. This is of a white colour, and has two hooks placed near the head; in short, it resembles in all the parts the maggot of the common flesh-fly. Multitudes of these small creatures live and move very briskly about in these substances for several weeks together; but at the end of that time, when they have arrived at their full growth, they enter into the nymph-state under a covering or case made of their own skin, which dries, and becomes of a brown colour. After eight or ten days in this state, the case is opened by the falling off of a small piece at the end, and the fly makes its way out. The fly is extremely small when its wings are not extended.

It does not exceed the size of the head of a middling pin; it is however very beautiful; the breast and body are yellow, the reticulated eyes are red, and the wings have all the rainbow-colours. The best way of procuring these little flies, which make a very beautiful microscope object, is to keep the matter, in which the worms are placed, in a glass, covered down with a paper; as soon as the cover is taken off, at the time of their being in the fly-state, they rise up at once in the form of a cloud; enough of them for observation will however remain about the sides of the vessel. When examined, they are found to have all the regular parts of the larger flies; their antennæ are oval and flattened, and their legs, and every other part, are as elegantly perfect, as they are seen to be in the most elegant large fly.

It is not known whether they are oviparous or viviparous; but this is to be observed, that they give us great light into the origin of animalcules in different fluids.

Since we see in these the evident course of nature in their origin, what prevents but that there may be numbers of flies yet smaller than these, whose eggs may be deposited in the fluids in which we find our microscope animalcules. Reaum. Hist. Inf. vol. ix. p. 82.

WINEBAGO, in *Geography*, a lake of North America. N. lat. 43° 50'. W. long. 87° 46'.

WINEBAGO River, a river of America, which runs from Winebago lake to Green bay into lake Michigan. The Winebago Indians inhabit near this river and lake, in about N. lat. 43° to 44°. W. long. 84° to 89°.

WINEBAGOES CASTLE, an Indian settlement in North America, near Winebago lake.

WINEE or BLACK RIVER, a river of South Carolina. See *BLACK RIVER*.

WINERSTA, a town of Sweden, in East Gothland; 18 miles N.W. of Linköping.

WING, in *Botany and Vegetable Physiology*, is generally used for any appendage to a seed, which serves to assist in its flight through the air. In this sense, the feathery crown of the Dandelion, and other syngenesious plants; the membranous expansion at the top of the scabious seed, so curiously and variously constructed in different species; the long feathery awn of the *Stipa*; and the delicate silky plumage

plumage of many seeds among the order of *Contorta*, are justly denominated wings. In a more limited and technical sense, the *Ala*, or wing, properly so called, is a thin membranous expansion, enabling the seeds to flutter to a small distance from their native capsule, rather than to fly very far. Such is found in *EMBOTHRUM*, *GREVILLEA*, *BANKSIA*, *CONCHIUM*, (see those articles,) as well as in our English genera *RHINANTHUS* and *SPERGULA*; in the latter we believe this part to vary, in degree at least. Gærtner meant to confine the term *ala* to a membranous expansion of the upper part of a seed, or seed-vessel, but he has not adhered to this intention. Winged capsules, which do not burst, are seen in the Ash and the Maple. One which does burst occurs in the curious exotic genus *BEGONIA*. The seeds of some umbelliferous plants, as *THAPSLIA*, have several wings; these are always lateral and longitudinal in that natural order; but it is far more general for them to be solitary. When the wing encompasses the seed, as in the beautiful instance of *Bignonia echinata*, figured in Gærtner, t. 52, that author properly adopts the term *ala*, and yet the expansion to which it applies is really a *margo membranaceus*, (membranous expansion,) furrounding the seed entirely, except at the very base.

The appellation of wing is given also to any membranous or leafy dilatation of a footstalk, or of the angles of a stem, branch, or flower-stalk, as well as of a calyx. The wings of a papilionaceous *corolla* are the two lateral petals, both alike, which embrace the base of the keel, and are sheltered by the standard. These spread remarkably in fine weather. They differ greatly in size and shape in different genera. See *PAPILIONACEÆ*.

WING, in *Geography*, a village of England, in Buckinghamshire, with 993 inhabitants; 7 miles N.E. of Aylesbury.—Also, a town of Sweden, in West Gothland; 40 miles E. of Gotheburg.

WING, in *Ornithology*. See *FEATHER*, and *FLYING*.

The wings are adapted for flight in all birds, except the dodo, ostriches, great auk, and the penguins, whose wings are too short for the use of flying: but in the dodo and ostrich, when extended, they serve to accelerate their motion in running; and in penguins perform the office of fins, in swimming or diving. The wings have near their end an appendage covered with four or five feathers, called the *bastard wings*: the lesser coverts are the *tetrices*: the greater coverts are those which lie beneath the former, and cover the quill-feathers and the secondaries. The quill-feathers, or *primores*, spring from the first bones of the wings, are ten in number, and broader on their inner than exterior sides: the secondaries are those that arise from the second part, or cubitus, are about eighteen in number, and equally broad on both sides. The primary and secondary wing-feathers are called *remiges*. The tertiaries are a tuft of feathers placed beyond the secondaries, near the junction of the wings with the body. This, in water-fowl, is generally longer than the secondaries, and cuneiform. The scapulars are a tuft of long feathers arising near the junction of the wings with the body, and lie along the sides of the back, but may be easily distinguished, and raised with one's finger. The inner coverts are those that clothe the under side of the wing.

The wings of some birds are instruments of offence: the anhimia of Marçgrave has two strong spines in the front of each wing; a species of plover has a single one on each; as have also the whole tribe of jacana, and the gambo, or spur-winged goose of Willughby. Pennant's *Genæsa of Birds*, pref. p. 4.

WINGS, among the *Fly-clafs*, afford several subordinate

distinctions of the genera of those animals, under the ancient general classes.

Several species of flies, while they are in a state of rest, or only walking, shew several regularly distinct manners of carrying their wings. The much greater numbers, however, carry them in a parallel or plain position: some being perpendicular to the length of the body without covering it, others covering the body without covering one another: the wings of others cross one another on the body of the animal, some of which round themselves there, the upper wing being more elevated on the middle of the body than on the sides. Some flies have their wings placed on their backs, and applied against one another, in a perpendicular position: the wings of others are applied obliquely against their sides, and meet above the body of their inner edges, forming a kind of hollow roof under which the body is placed; others form at their junction on the back a flat depressed roof, and others have them meeting under their bellies.

The structure of the wings of different flies might also furnish matter of farther distinctions. The greater part of them are of a fine structure, and represent the finest gauze, and are equally transparent, or nearly so, in all parts. Some flies, however, have wings of a less degree of transparency, and some even opaque ones. Others of the four-winged flies have obscure spots also distributed near their very transparent texture; such are the wings of the scorpion-fly; and some of the two-winged flies have wings partly opaque, partly pellucid, the opaque spots being separated by transparent lines. Reaumur's *Hist. Inf.* vol. iv. p. 136, &c.

WINGS of Butterflies. The beautiful wings of this genus of insects are distinguished from those of the fly-kind, by their not being thin and transparent, like them, but thicker and opaque. This opacity in them is owing only to the dust which comes off from them, and sticks to the fingers in handling them, and it is also to this dust that they owe all their beautiful variety of colours. The earlier naturalists, for this reason, distinguished these insects by the appellation of such as had farinaceous wings. The use of the microscope has taught us, that this dust is not the result of some other substance broken into fragments; but every particle of it is a regularly figured body, made for the place and order it has in the covering of the wing.

The several species of butterflies, and even the different parts of the same wing, afford these bodies of different shapes and figures. Most of the authors who have written of microscopic objects, have given the figures of the principal varieties of these; but no one has given so many as Bonani in his *Micrographia*, in which work the figures of the various kinds take up four quarto plates.

It has been the general custom of authors to call these feathers; but they are by M. Reaumur, with much greater justice, called scales. Their structure has no resemblance to that of feathers, for they are little flat and thin bodies, of more or less length, and always having a short pedicle which enters into the substance of the wing.

When the wing of a butterfly is viewed by a microscope, the arrangement of these several bodies in it is seen to be extremely beautiful and regular. The scales lie as regularly and evenly one over another, as the tiles on a house or the scales on the fish-kind, every series of them covering a small part of that series which runs below it. The upper and under part of the wing are equally furnished with these, and there is no species of this creature, in every wing of which there are not several figures of these scales in several parts.

The structure of the wing itself which supports these several scales, hairs, &c. is very worthy our attention. In order to examine this, it is necessary to rub off all the dust or scales. We then find that the wing itself is framed of several large and strong ribs, which all take their origin at that part where the wing is fixed to the body, and thence extend themselves along the several sides of the wing. The largest and thickest of these surrounds the outer edge of the wing, the largest next to this extends itself round the interior edge, and the others direct their course along the middle of the wing, and then divaricate, and become ramified in the manner of the ribs in the leaves of plants. The substance which connects and fills up the spaces between these ribs, is of so peculiar a nature, that it is not easy to find any name to design it by, at least there is no substance that enters the composition of the bodies of the larger animals, that is at all analogous to it: it is a white substance, transparent and friable, and seems indeed to differ in nothing from that of the large and thick ribs, but in that it is extended into thin plates; but this is saying but little toward the determining what it really is, since we are as much at a loss to know by what name to call the substance they are composed of. Malpighi, indeed, calls them bones; but though they do serve in the place of bones, rendering the wing firm and strong, without making it heavy, and are, when cut transversely, found to be hollow; yet, when strictly examined, they do not appear to have any thing of the structure of bones, but appear rather of the substance of scales, or of that sort of imperfect scales, of which the covering of those insects which we call crustaceous is composed.

The wings of butterflies, thus large, and thus light, are very well able to sustain them a long time in the air, and thus they might be expected to fly better than most other insects; but many people have observed the irregular manner in which these insects usually fly, which is not straight forward, but up and down, and to one side and the other: this has been supposed owing to some imperfection of the wings; but, in reality, it is their great perfection that enables the creatures to do this, and this manner of flying is absolutely necessary to the preservation of their life, as birds of many kinds are continually after them while they are on the wing; and it is a pleasant sight to observe in what manner this sort of dodging motion in the butterfly disappoints the bird that flies straight at it, and often preserves it safely for a long way together.

The beautiful variety of colours, seen in the wings of these insects, is owing to the scales and feathers. Reaumur's Hist. Inf. vol. i. part i. p. 255, &c.

WINGS of Gnats. These are of a very curious structure, and well worthy the use of the microscope, to see them distinctly.

It is well known that on touching the wings of butterflies, a coloured powder is left on the fingers, which, though to the naked eye it appear a mere shapeless dust, yet when examined by the microscope, it is found to be very regularly-figured beautiful bodies, encompassed with a furbelow of long feathers, and with veins or ribs that seem to strengthen them, in form of feathers or scales, or sometimes beset with prickles: these are of various figures, and all of them very elegant. The generality of flies have nothing of this kind; but the close examination of the wings of the gnat will shew, that they are not wholly destitute of them; they are much more sparingly bestowed indeed upon the gnat than on the butterfly, but then they are arranged with great regularity. Between the ribs of the wings there is extended a very thin transparent membrane, full of little

black sharp-pointed hairs, ranged throughout with the utmost regularity. The wings in different sorts of gnats are very different: some have a border of long feathers, others of short ones, and others have none at all. Reaumur's Hist. Inf. vol. iv. p. 577. Baker's Microsc. 8vo. 1743, p. 204.

WINGS, Warbling of the. See **WARBLING**.

WINGS, in Heraldry, are borne sometimes single, sometimes in pairs, in which case they are called *conjoined*; when the points are downward, they are said to be *inverted*; when up, *elevated*.

WINGS, in Gardening, &c. denote such branches of trees, or other plants, as grow up aside of each other.

Quintiny says, the term is particularly applied to artichokes, whose wings, or *ale*, are the lesser heads, or fruits, that grow up with the principal one on the same stalk.

WINGS, Ale, in the *Military Art*, are the two flanks, or extremes of an army, ranged in form of battle; being the right and left sides thereof, and including the main body.

The cavalry are always posted in the wings, *i. e.* on the flanks, on the right and left sides of each line; to cover the foot in the middle.

Pan, one of Bacchus's captains, is said to have been the first inventor of this method of ranging an army; whence, say they, it is, that the ancients painted him with horns on his head; what we call wings, being by them called *cornua*, *horns*. This at least is certain, that the method of arranging in wings is very ancient. The Romans, we know, used the term *ale*, or wings, for two bodies of men in their army; one on the right, the other on the left, consisting each of four hundred horse, and four thousand two hundred foot usually, and wholly made up of confederate troops. These were designed to cover the Roman army, as the wings of a bird cover its body.

The troops in these wings they called *alares*, and *alares copiae*; and we, at this day, distinguish our armies into the *main body*, the *right* and *left* wings.

WINGS are also used for two files, that terminate each battalion, or squadron, on the right and left. The pikes used to be ranged in the middle, and the musqueteers in the wings.

WINGS, in Fortification, denote the longer sides of horn-works, crown-works, tenailles, and the like outworks, including the ramparts and parapets, with which they are bounded on the right and left, from the gorge to their front.

These wings, or sides, are capable of being flanked, either with the body of the place, if they stand not too far distant, or with certain redoubts; or with a traverse made in the ditch.

WINGS, in a Ship, the places next the side upon the orlop, usually parted off in ships of war, that the carpenter and his crew may have free access round the ship in time of action, to plug up shot-holes, &c.

WINGS are also the skirts or extremities of a fleet, when it is ranged into a line a-breast, or when bearing away upon two sides of an angle.

It is usual also to extend the wings of a fleet in the day-time, in order to discover any enemy which may fall into their track. To prevent separation, however, they are commonly summoned to draw nearer to the centre of the squadron before night, by a signal from the commander-in-chief, which is afterwards repeated by ships in the intervals. Falconer.

WING-Transom, the uppermost transom in the stern-frame of a ship, &c., upon which the peels of the counter-timbers are rested. It is by some called the main-transom.

WINGS,

WINGS, *Goose*. See GOOSE.

WING, *St. Michael's*, is the name of a military order in Portugal, instituted, according to the Jesuit Mendo, in 1165; or, according to di Michieli, in his *Tesoro Militar. de Cavalleria*, in 1171. Its institutor was Alphonfus Henry I. king of Portugal; and the occasion was a victory gained by him over the king of Savil, and his Saracens; for which he thought himself beholden to St. Michael, whom he had chosen for his patron in the war against the infidels.

The banner they bore was a wing resembling that of the archangel, of a purple colour, encompassed with rays of gold. Their rule was that of St. Benedict; the vow they made was to defend the Christian religion, and the borders of the kingdom, and to protect orphans. Their motto, *Quis ut Deus!*

WING-Walls, of a bridge or lock, are splaying-walls for diminishing the width of the canal to such bridge or lock, and for keeping up the banks.

WINGÉ, in *Geography*, a river of France, which runs into the Demer, 2 miles W. of Arschot.

WINGED, in *Botany*, a term applied to such stems of plants as are furnished, all their length, with a sort of membranous appendage.

Several kinds of thistles have winged stalks and branches.

WINGED Leaves are such as consist of divers little leaves, ranged in the same direction, on each side of a rib or stalk, so as to appear no more than one and the same leaf. Such are the leaves of agrimony, acacia, ash, &c. See WING.

WINGED Seeds are such as have down or hairs on them, by which the wind taking hold blows them to a distance.

WINGED Stalk. See STALK.

WINGED, in *Heraldry*, is applied to a bird when its wings are of a different colour, or metal, from the body.

Winged is also applied to any thing represented with wings, though contrary to its nature; as *winged* or *flying hart*, &c.

WINGER, in *Geography*, a town of Norway, in the province of Aggerhuus; 2 miles S. of Kongswinger.

WINGHAM, a village and parish in the hundred of its own name, and lathe of St. Augustine, in the county of Kent, England, is situated 34 miles E. from Maidstone, and 62 E. by S. from London. A college of a provost and six secular canons was projected here by Kilwardby, archbishop of Canterbury, but settled and endowed by his successor, Peckham, in 1286. It was valued at 84*l.* per annum at the general suppression. By Edward VI. the college, with the patronage of the church and all tythes, were granted to sir Henry Palmer. The building, now called the college, and which formed the mansion of the Palmers, appears to have been the provost's lodge. The church contains memorials of the Palmers and the Oxendens, who have a seat at Deane, in the parish. A double row of stalls still exists in the chancel. Wingham gives a title to earl Cowper, who, however, has no estate in the parish. It gave birth to Henry de Wingham, chancellor of England, bishop of Winchester, and afterwards of London. In 1811 the inhabitants of the parish were 859, who occupied 162 houses.—*Beauties of England*, Kent, by E. W. Brayley.

WINGHAM's Island, a small island in the North Pacific ocean, near the W. coast of North America; 3 miles N.W. of Kaye's island. N. lat. 60° 4'. E. long. 215° 46'.

WINGROD, a town of Austrian Poland, in Galicia; 16 miles N.W. of Sniatyn.

WINHALL, a township of Vermont, in the county of Bennington, with 429 inhabitants; 30 miles N.E. of Bennington.

WININGEN, a town of France, in the department of the Rhine and Moselle, on the N. side of the Moselle; 5 miles W. of Coblenz.

WINKEL, a town of France, in the department of Mont Tonnerre; 14 miles W. of Mentz.

WINKELMAN, *Abbé JOHN*, in *Biography*, a German antiquary, was born at Stendal, in the Mark of Brandenburg, in 1718. Although born in very humble life, he fortunately enjoyed favourable opportunities of cultivating his talents in that department in which he afterwards attained to eminence. He had arrived at the age of 37 years before he was known to the public as an author. His first work was "Reflections on the Imitation of the Greeks in Painting and Sculpture;" and it was received in a manner that very much contributed to establish his reputation. At the court of Augustus, king of Poland, he was profelyted to the Catholic faith, more, as some have said, by arguments addressed to his worldly interest, than to his spiritual welfare. It is certain, however, that he much wished to visit Italy for the sake of examining those masterpieces of art that were to be found in that country. With this view he left Dresden, and in passing through Florence in 1756, he made a descriptive catalogue of the antiquities in the collection of the celebrated baron de Stofsch, which seemed to introduce him with advantage to Rome, whither he proceeded towards the close of this year. His acquaintance with the famous painter Mengs, Bianconi, and several other ingenious artists, forwarded his access to two of the most celebrated literary men at Rome, cardinal Passionei and the prelate Giaconelli, from whose library and learning he derived much useful information, so that he was soon acknowledged as a man of fine taste, and a distinguished connoisseur in works of art. Assuming the ecclesiastical habit, he succeeded the abbé Venuti as keeper of the pope's cabinet of antiquities; and he was also appointed copyist in the library of the Vatican. Under the patronage of the pope, who increased his income out of his privy-purse, he completed his *History of Art among the Ancients*, and then left Rome in 1768 to visit his friends in Germany, and to revise his work to be translated into French by M. Toussaint of Berlin. On his return to Rome by way of Trieste, he was assassinated, in June 1768, by a wretch who had joined him on the road, and who had so far gained his confidence, that he had shewn him some gold medals and valuable presents which he had received at Vienna. "Abbé Winkelman," says one of his biographers, "was of the middle size, with a very low forehead, a sharp nose, and black hollow eyes, which gave him rather a gloomy appearance. An ardent and impetuous disposition often hurried him into extremes. Naturally enthusiastic, he frequently indulged an extravagant imagination; but as he possessed a strong and solid judgment, he knew how to give things their just value. In consequence of this turn of mind, as well as a neglected education, he was a stranger to cautious reserve. If he was bold in his decisions as an author, he was still more so in his conversation, and often made his friends tremble for his temerity." The translation of his *History of the Arts* was completed only in part by Toussaint. Another French translation was published by Huber, professor at Leipsic. It is said that the last French translation is far preferable to the first, as it was made from an enlarged edition of the original, printed at Vienna in 1776, after a MS. left by the author. Among the other works of Winkelman were, "Letters on the Discoveries made at Herculaneum," translated into English by Mr. Gough; "Unpublished Monuments of Antiquity, such as Statues, ancient Paintings, engraved Stones, Bas-Reliefs, in Marble and

and Terra Cotta," of which there is a French translation from the Italian, Paris, 1808, 3 vols. 4to. with plates; "On Allegory, or Treatises on that Subject," 2 vols. 8vo.; and "Remarks on the Architecture of the Ancients," 8vo. Winkelman's "Letters to his Friends" were published in German, in 2 vols. 8vo., with an account of his life prefixed by Heyne. *Nouv. Dict. Hist. Gen. Biog.*

WINKOOP'S BAY, or *Wine Cooper's Bay*, in *Geography*, a large bay on the south coast of Java. S. lat. $7^{\circ} 5'$. E. long. $106^{\circ} 38'$.

WINKOOP'S *Island*, a small island near the south coast of Java. S. lat. $7^{\circ} 28'$. E. long. $106^{\circ} 36'$.

WINKOOP'S *Point*, a cape on the south coast of Java. S. lat. $7^{\circ} 25'$. E. long. $106^{\circ} 36'$.

WINLATON, a township of Durham; 6 miles W. of Newcastle.

WINNEBAGO. See WINEBAGO.

WINNENBURG, a citadel of France, in the department of the Sarre, which heretofore gave name to a lordship within the archbishopric of Treves; 1 mile N.W. of Cochem.

WINNENDEN, a town of Wurtemberg. In the year 1693, this town was laid in ashes by the French; 12 miles E.N.E. of Stuttgart. N. lat. $48^{\circ} 53'$. E. long. $9^{\circ} 30'$.

WINNICZA, a town of Poland, in the palatinate of Braclaw; 32 miles N.N.W. of Braclaw.

WINNING OF HAY, in *Agriculture*, a term sometimes applied to the operation of making hay in certain states of the weather. See HAY-Making.

WINNINGE, in *Geography*, a river of Lancashire, which runs into the Lune, 6 miles N.E. of Lancaster.

WINNINGEN, a town of Westphalia, in the principality of Halberstadt; 4 miles N. of Ascherleben.

WINNIPEG, or WINIPIC, a lake of Upper Louisiana, being the great reservoir of several large rivers, and supposed to be the largest of the inland seas, near the heads of the Mississippi, which discharges itself by the river Nelson into Hudson's bay. It is connected with other lakes to the N.W., and has, from the rivers entering into it, an inconsiderable portage to the waters of lake Superior. This lake is said to be 240 miles in length, and from 50 to 100 in breadth, though in some places it is hardly five. N. lat. $52^{\circ} 10'$. W. long. $97^{\circ} 30'$.

WINNIPEG or *Winipic River*, a large body of water, interspersed with numerous islands, causing various channels, and interruptions of portages and rapids. The lake Du Bois discharges itself at both ends of an island, on which is the carrying-place out of the lake, and which is named Portage du Rat, in N. lat. $49^{\circ} 37'$, and W. long. $94^{\circ} 25'$, about 50 paces long, and forms this river. In some parts, the river has the appearance of lakes, with steady currents: its winding course to the Dalles is estimated at 8 miles; to the Great Décharge $25\frac{1}{2}$ miles, which is a long carrying-place for the goods; from thence to the Little Décharge $1\frac{1}{2}$ mile; to the Tunejaune Portage $2\frac{1}{2}$ miles; then to its galet or rocky portage, 70 yards; $2\frac{3}{4}$ miles to the Tune Blanche, near which is a fall of from four to five feet; $3\frac{1}{2}$ miles to Portage de l'Isle, where is a trading port, and about 11 miles on the N. shore a trading establishment, which is the road, in boats, to Albany river, and from thence to Hudson's bay. There is also a communication with lake Superior, through what is called the Nipigoes country, that enters the lake Winipic above 35 leagues E. of the Grande Portage. Mackenzie's *Voyages*, &c. *Introd.* p. 60.

WINNIPEG, *Little*, a lake of North America, 80 miles long and 15 wide. N. lat. $52^{\circ} 10'$. W. long. $100^{\circ} 15'$.

WINNIPISIOGEE, or WINNIPISSIOKEE, a lake of New Hampshire; 80 miles N. of Boston. N. lat. $43^{\circ} 35'$. W. long. $71^{\circ} 18'$.

WINNOW, in *Agriculture*, signifies to fan, or separate corn from the chaff by wind.

WINNOWER, and WINNOWER-Machine. See FAN-Machine, and THRESHING-Machine.

WINNSBOROUGH, in *Geography*, a town of South Carolina; 30 miles N. of Columbia. N. lat. $34^{\circ} 28'$. W. long. $81^{\circ} 15'$.

WINNY HAY, in *Agriculture*, a term applied to hay in some conditions of it. See HAY.

WINSCHOTE, or WINSCHOTTEN, in *Geography*, a town of Holland, in the department of Groningen, near which the Spaniards were defeated by Louis, brother to the prince of Orange, on the 24th of May 1568. The Spaniards lost 2500 men, all their baggage, and six pieces of cannon. This was the first battle fought on account of the Revolution, and gave the prince a happy preface of success; 19 miles E. of Groningen.

WINSDER, a river of Norfolk, which runs into the Yare, 12 miles W.N.W. of Norwich.

WINSEN AM DER ALLER, a town of Westphalia, in the principality of Luneburg, on the^e Aller; 6 miles below Zell.

WINSEN *am der Lube*, a town of Westphalia, in the principality of Luneburg, on an island in the lake; 12 miles S.E. of Hamburg.

WINSLOW, JAMES BENIGNUS, in *Biography*, an eminent anatomist, was born in 1669 at Odenfee, in the isle of Funen, and having studied a year under Borrichius, was sent with a pension from the king of Denmark to seek improvement in the principal universities of Europe. In 1698 he became a pupil of the celebrated anatomist Duverney at Paris, and during his residence in this capital, he abjured Protestantism, and was confirmed by Bossuet, assuming in addition to his own baptismal name that of his converter, Benignus. Haller denominates Winslow "simple and superstitious," and of course his conversion to the Catholic faith afforded no great occasion for triumph. This event, however, detached him from his family and native country, and was the means of fixing his abode in France, where the patronage of Bossuet was highly favourable to his advancement, and served to obtain for him the degree of doctor in 1705. In 1707 Duverney recommended him to be an élève of anatomy in the Academy of Sciences. He afterwards read lectures of anatomy and surgery for Duverney at the royal garden; and in 1743 was promoted to the professorship in this institution. In the meanwhile, he communicated several papers on anatomical and physiological subjects to the Academy of Sciences, by which body, as well as by the Royal Society of Berlin, he was admitted into the number of associates. His great work, mentioned by Haller as superfluous all former compositions of anatomy, and entitled "Exposition Anatomique de la Structure du Corps Humain," first appeared at Paris in 1732, 4to. It was frequently reprinted, and translated into various languages; and is still regarded as of standard authority. Winslow planned, but never finished, a larger work, of which this was merely an abridgment, and he was also the author of disputations and treatises on particular topics. He died in 1760 at the advanced age of 91. Haller. *Eloy. Gen. Biog.*

WINSLOW, in *Geography*, a market-town in the county of Buckingham, England, $6\frac{1}{2}$ miles from Buckingham, and 51 N.W. from London. The market, now inconsiderable, was granted in 1235 to the abbot of St. Alban's, lord of the manor,

manor, by king Offa. The manor is now the property of William Selby, esq., who has a seat in the town. The parish-church, a spacious structure consisting of a nave, two aisles, a chancel, and a tower, contains no monuments of note. According to the population return of 1811, the houses in the parish were 223, and the inhabitants 1222. Here is a small market on Thursdays, and five annual fairs.—*Magna Britannia*, by the Rev. D. Lyfons and S. Lyfons, esq. 4to. 1806.

WINSLOW, a town of the province of Maine, on the Kennebeck, in the county of the same name, containing 658 inhabitants; 88 miles N.N.E. of Portland.

WINSTER, a small market-town in the hundred of High Peak, and county of Derby, England, is situated 5 miles W. by N. from Matlock, and 152 miles N.N.W. from London. The manor belonged to Henry de Ferrars when the Domesday-survey was taken. At a later period it was held by the Mountjoys, who were succeeded by the Meynells. The latter sold it to the freeholders in the reign of queen Elizabeth. The town affords nothing worthy of particular notice. It has a chapel of ease to the parish of Youlgrave, of which Winster forms a part; and also a chapel for the Wesleyan Methodists. A market is held on Saturdays, which appears to be by prescription; for there is no grant of it on record: till lately here was an annual fair, but it is now discontinued. The population return of the year 1811 states Winster to contain 217 houses, and 852 inhabitants; the latter are chiefly employed in the mining business, and in the inferior branches of the cotton trade. On the commons, in the vicinity of the town, are several cairns, or stone barrows, and also two or three barrows of earth: in one of the latter, which was opened in the year 1768, two glass vessels were discovered, about nine inches in height, containing a pint of water, of a light green colour, and very limpid. With these a silver collar or bracelet was found, together with some small well-wrought ornaments, several beads of glass and earth, and remains of brass clasps and hinges, with pieces of wood, that seemed to have belonged to a box in which the ornaments had been deposited. These antiquities induced Mr. King to suppose the barrow to have been raised over some Briton of distinction, though long after the Romans were in possession of the island.—*Beauties of England and Wales*, vol. iii. Derbyshire; by J. Britton and E. W. Brayley, 1803. *Lyfons' Magna Britannia*, vol. v. Derbyshire, 1817.

WINSTER, a river of the county of Lancaster, which runs into the Ken, at its mouth.

WINTBERG, a town of Prussia, on the Curisch Haff; 14 miles N. of Preckol.

WINTENAU, a town of the duchy of Stiria; 2 miles S. of Marburg.

WINTER, —, in *Biography*, a German opera composer, of great abilities, who succeeded Bianchi at our Lyric theatre in 1803; during which year he produced, in 1803-4, the music of the ballet of Achille and Deidamia, and for Mrs. Billington's benefit.

WINTER, one of the four seasons or quarters of the year.

Winter properly commences on the day when the sun's distance from the zenith of the place is the greatest, and ends on the day when its distance is at a mean between the greatest and least.

Notwithstanding the coldness of this season, it is proved, in astronomy, that the sun is really nearer to the earth in winter than in summer. The reason of the decay of heat, &c. see under HEAT.

Under the equator, the winter, as well as the other seasons,

return twice every year; but all other places have only one winter in the year; which, in the northern hemisphere, begins when the sun is in the tropic of Capricorn; and in the southern hemisphere, when in the tropic of Cancer: so that all places in the same hemisphere have their winter at the same time.

WINTER *Management of Flowers, in Gardening*, among florists, mostly consists in placing them in proper situations and exposures, in properly protecting them, in duly earthing them on the approach of the spring season, and some other matters of less consequence. Different kinds of flower-plants require different sorts of management in these respects; but in those of the primrose kind, especially in the auricula, (see AURICULA and PRIMULA,) the plants, after being placed out in proper frames, in a full southern exposure, from about the middle of October throughout the winter, and having a rather warm protection given them the whole of that time, when the weather is severe, should in all the autumnal and winter months, until the beginning of April, or later, be exposed during the day to the full open air, by wholly removing the glasses, except in the time of very heavy rains, and severe frosts or storms, though the common practice is that of keeping them on, and only letting in air by raising the lights behind. In the mid-winter season they should be kept very dry, as severe frost has in that case less effect on the roots; consequently, when rain obliges the lights to be kept on, they should be raised behind. Heavy rain, or much wet, is very prejudicial and sometimes destructive to these plants, which are otherwise hardy. Much exposure to the free air in dry weather has likewise great effect on the richness and brilliancy of their ground colours and good spring bloom, as well as on their health, vigour, and hardiness. In the afternoon, as about four o'clock, however, the plants should be covered by the lights at this season in a close manner, and have two or three thicknesses of mats thrown over them, to remain until about nine o'clock on the morning following, when, should there not be rain, hail, or snow, they may be exposed to the full open air as above; but in the contrary circumstances, the mats should only be removed so as to give light, air being plentifully let in behind. In the two beginning months of the year much must depend on the state of the weather; when mild and open, the plants may be managed nearly as above; but in severe frost and snow much more caution must be used in regard to exposure, so as not to have the mould of the pots much frozen, as the bloom is now beginning to form, and would be injured thereby; but in long frosts air should be let in as much as possible in the above manner, and light be given, with the influence of the sun, when there is any, in the middle of the day; the plants being always closely shut and covered up by three o'clock in the afternoon. Though the plants should be very dry, they should have but little water, either in rain, or from the watering-pot, in the two preceding months, and only a small quantity, or some small light southerly showers in these, so as to render the ground in a moderately moist condition. Towards the middle or end of February, the plants should be dressed, cleaned, and new-earthed with fresh mould for the spring, when there is mild open weather, removing those from the small pots into larger, and exposing them fully to the gentle rains and showers, but constantly defending them well from frosts, hail, and storms, as they now begin to shoot new fibres more quickly, and to grow fast. This manner of managing them should be continued until nearly the middle of March, after which they should be covered more warmly in the nights, for fear of frosts, and that they may be bloomed very fine.

From the middle period of the above month, and through the following, they must also be defended from frost, in order to promote the coming bloom. Great care and attention are especially necessary for blooming the plants well from the above time in March to near the end of the succeeding month, as in this time they will mostly attain their greatest perfection and beauty. It is only necessary, as it is thought, for blooming such flower-plants in the greatest perfection, to have them continually under glass, night and day, for about twenty-four of the last days, as they will then have their middle pips well expanded. In very strong sun they must be slightly shaded by a thin mat, but in other cases they may be thrown open and exposed to the full free air.

After the beginning of April, as the fifth or sixth, the glasses of the frames are to be kept completely over the plants night and day, until they are in full bloom, only letting in proper supplies of air from behind the frames, and giving the shade of old thin mats when necessary. This mode is to be pursued to about the middle of this month; but the plants are not to be over-hastened in their bloom by too much sun, as that may fade their fine colours; but in such cases they must be removed from the full southern exposure to a full eastern one, though by no means yet to a northern aspect, as that would endanger their bloom; if the season be suitable, the protection of a privet-hedge, wall, or paling-fence, is the most proper, being covered by hand-glasses; when about the end of the month, they may be removed to a northern exposure on stages, or in other proper places.

In this finishing blooming eastern exposure, all the mats and other coverings should be taken off from the glasses that are placed over the flowers, about seven o'clock in the morning, and in sunny weather the plants be shaded from about nine to twelve or one, the thin mats being then removed. The covering-glasses are to be prepared by well washing, and other means.

The flowers in blooming are mostly much benefited by having a south-west exposure as much as possible, and by carefully attending to the north and north-east winds, as well as by receiving all mild moderate rains from about the beginning of February until towards the end of March. In the latter part of this time, before the trusses are too forward, and the blossoms open, three or four hours rather heavy mild rain greatly promotes the swelling of the pips, and much increases the size of the foliage, especially if care be taken immediately after it is over to shut the flowers close down, and cover them up in a warm manner, as below. Watering them from a pot with a fine rose in a warm sunny day all over the leaves in the afternoon, in the manner of rain, and directly covering them up warmly while the sun is upon them, has likewise been found beneficial. They are now, too, to be well guarded from late frosts, as they are so soon destroyed by them.

In the late winter, or early spring, night-covering, as from the middle of the above month, the following mode has been found highly beneficial, in not only repelling the cold frosty night-air, but in assisting the bloom, and preventing its being checked in any way thereby.

The heat at this period being usually from about forty-five to fifty degrees in the day-time, the flowers may be exposed to the open air in it, and in covering them in for the night, be kept nearly to that state; which is only to be effected by an artificial covering of some sort or other, for other sorts of heat do not answer the purpose; as those of the warm blanket, horse-cloth, sheep-skin, and other similar kinds, laid next to the glasses, over which mats may be placed so as fully to protect the flowers, and keep the

other coverings from being injured by rain or other wetness. Where wood-frames and not brick ones are used, it is also often necessary to have hay, fern, straw, or some other such material, applied on the outsides of them, to guard against the penetration of the cold frosty air, as is otherwise liable to be the case in severe seasons. But such full coverings should not be had recourse to in the winter season sooner than about the middle of March, as they might not only injure the fine strong blooming plants, but counteract the good effect they are intended to have in assisting nature to gradually bloom the flowers in fine condition as the season approaches. The keeping the flowers so warm on the nights at this period of the season is supposed to prevent any check to the vegetation of the plants; and another great effect which it has is, that as soon as the pips open, they proceed vigorously, expand freely, and come out level, fine, and nearly flat; while, if they once get a complete *chill* by cold night air, their blossoms will not expand flat, but on the contrary, ruffle or furlbelow.

In the leaves of the auricula and some other kinds of plants, there is as much variety produced by these means in the shades of their green as in the colours of their flowers. The green of the leaves, or *grafs*, as it is termed, in this sort of flower-plants, should constantly be that which affords the best contrast, and has the most power in setting off the flower to which it belongs. Different varieties in the shape of the leaves also proceed from the nature of the culture and management, as well as from the raising them from seed. They have from these causes leaves with smooth even edges, with thick and fleshy edges, and with thin edges. These varieties in the leaves of such plants are often of importance to the florist in different ways. In the grafs or green leaves of these plants, there is likewise some variety in the mealy dust or farina which is upon them: in some the whole plant is nearly covered with it; but those with blueish or pea-green leaves are commonly the most powdered with this sort of dust, which contributes not only to the beauty of the plants, but serves in some degree to preserve them from the effects of the scorching heat of the sun during the summer season.

The different other fine flower-plants are to have something of the same sort of winter-management pursued for them, only making proper allowances and distinctions, in so far as their differences in the nature of their growths or other habits are concerned.

The diversities of the auricula, as well as most other flower-plants, owe their present perfection, in a great measure, to the care, ingenuity, cultivation, and management of the florist-gardener, and some of those private individuals who cultivate flowers for the amusement and delight which they afford. By these means, this and many other sorts have been wonderfully improved, which were at first single and simple; and their variety, size, and beauty, have been increased in an astonishing manner. The sportiveness of nature has likewise done much, as is evident in so many flower-plants; as in the daisy, ranunculus, the anemone, the stock, the wall-flower, the pink, the carnation, the Siberian larkspur, and a vast many more.

There is, indeed, something extraordinary in the great and uncommon diversity of the colours, and the differences of the shades and hues of this as well as some other flowers; and it is not less singular or true that out of more than an hundred flowers of this sort, which are raised from seed in this way, there will not, perhaps, be two which are exactly alike; and that yet, in all these deviations, the changes take place in the most naturally pleasing, agreeable, and unthought-of manner possible.

By attention to proper winter and other management, still more diversity and variety may most probably be produced in this and different other flowers.

WINTER, among *Printers*, that part of the printing-press, serving to sustain the carriage, &c. See PRINTING-PRESS.

WINTER's-Bark, *Cortex* WINTERI, or WINTERANUS, WINTERA *Aromatica*; which see. See CORTEX.

This is one of the largest forest-trees upon Terra del Fuego, often rising to the height of fifty feet. Dr. Solander has given an accurate botanical description of it, illustrated by a figure, in *Med. Obs. and Inq.* vol. v. p. 46, &c. Its leaves are ever-green, smooth, oval, and entire; the flowers consist of seven petals, with from fifteen to thirty stamens, and from three to six germs, terminating in as many stigmas; each germ becomes a seed-vessel, containing several seeds: the bark of the trunk of the tree is externally grey, and very little wrinkled. The pieces of this bark brought over by the Dolphin are about three or four inches square, of different degrees of thickness, from one-fourth to three-fourths of an inch. It is of a dark brown cinnamon colour, an aromatic smell if rubbed, and of a hot, pungent, spicy taste, which is lasting on the palate, though imparted slowly. A watery infusion of it struck a black colour with a solution of green vitriol. An infusion of two ounces, coarsely powdered, yielded on evaporation two drachms and twenty-four grains of extract: the same quantity, with rectified spirit, afforded two drachms of extract.

This bark, though much celebrated as an antiscorbutic by the first discoverers, is unknown in the practice of physic; the *canella alba*, (see CANELLA,) which is totally different from it, having been confounded with it in the shops; and no quantity having been brought to Europe, except as a curiosity, till the return of the ships sent out on an expedition to the South seas. It has been thought to be a useful antiscorbutic; but it seems to possess in this respect no advantage over the other pungent aromatics, and it is now generally superseded by the *canella alba*.

From some experiments on this bark by Dr. Morris, it appears to be an astringent of a particular kind, and therefore likely to be of use in several manufactures; and that water is the proper dissolvent of it.

It is hoped that this tree, no less useful than elegant, may be cultivated in our country, where it would probably grow luxuriantly, as in a much warmer region than its own, and furnish, not only a valuable ever-green, bearing our severest winters, but also a valuable medicine. *Med. Observ. ubi supra.*

WINTER-Barley, in *Agriculture*, a term applied to an excellent sort, which is put into the ground in the autumn, and which stands the winter. It is found by some farmers to be very productive in its nature, and when made into malt to form a much stronger sort than that which is produced from common barley.

In some districts, it is a good deal sown and cultivated as an early sheep-feed, in which intention it often answers very well. See BARLEY.

WINTER-Berry. See PRINOS.

WINTER-Bloom. See AZALEA.

WINTER-Cherry. See PHYSALIS *Alkekengi*.

WINTER-Cresses. See ERYSIMUM *Barbarea*.

WINTER-Crops, in *Agriculture*, a term used to signify all such as are put into the soil to grow or rise at that time of the year, which are capable of withstanding that severe season, or which can be converted to the purpose of fodder for animals at that inclement and necessitous period.

WINTER-Fallow. See FALLOW.

WINTER-Garden, a term often applied to that kind of ornamental garden which is chiefly for use and amusement at that season of the year. It has been advised by Mr. Loudon, that a winter-garden should contain all such trees, shrubs, plants, and other vegetable productions, as are in a state of perfection, or retaining their beauty and verdure, at and during this season, in the most complete manner; as most of the ever-green tribe or class of trees and shrubs, many flowering plants, as the aconite, snow-drop, Christmas-rose, and several others of similar kinds; that these should be grouped and arranged in the natural manner in such garden-grounds; and that a dry gravel or other similar kind of walk should be conducted throughout, or carried round-about the whole, in the view of being walked upon at this season without inconvenience; that these sorts of gardens should be situated near the mansion or residence, in order that they may be comfortably and conveniently approached in the different winter months; and that the conservatory too, as well as some other such houses, should be placed in them.

WINTER-Green, in *Botany*. See PYROLA.

The greater round-leaved winter-green, or *pyrola rotundifolia major*, is generally brought over from Switzerland with other vulnerary plants, in which class it is ranged, and by some greatly commended. Miller.

WINTER-Green, *Ivy-flowering*. See KALMIA.

WINTER-Green, with *Chickweed Flowers*. See TRIENTALIS.

WINTER-Heyning, in our *Statutes*, a season between the eleventh day of November, and the three-and-twentieth of April, which is excepted from the liberty of commoning in the forest of Dean, &c. Stat. 20 Car. II. cap. 3. Blount.

WINTER-Pears, in *Gardening*, such as will keep, and are ready for use in that season. It has been suggested in a paper in the second volume of the "Memoirs of the Caledonian Horticultural Society," that in the cultivation of pears of this sort, those of the *sky-bearing* sorts should be carefully avoided; that they should be suited as much as possible to the nature of the climate or region where they are to be grown; that they should have their situation in a proper exposure, and in a proper soil; that they should be well pruned, trained, and managed, in all other respects; that those kinds which can be most depended on be had recourse to; that new varieties may probably be raised from seed with advantage in this view; and that endeavours should be made to bring into use any good late sorts of this fruit.

The number of winter-pears in the northern parts of this island are supposed to be scanty indeed. That if the few that have been favourably spoken of by some cannot be had, there are not, it is believed, above five more to be depended on in these situations; which are these, the swan-egg, achon, brier-bush, the John Monteth, and to which may be added the muirfowl-egg, which keeps there much longer than the swan-egg, and must be allowed to be a winter-pear, though commonly set down as an autumn fruit. The swan-egg has there, it is said, never kept good longer than the end of November, while the muirfowl has sometimes remained in good preservation until towards the end of April. In the then last season they were taken from the tree, it is said, sooner than usual; consequently were earlier ripe or fit to eat, and of course have decayed more speedily, than ordinary. They were, however, perfectly good until towards the end of January in the following year, after which they spoiled in a very sudden manner. The muirfowl-egg

may also, however, with great safety, be allowed to remain on the tree ten or twelve days longer than the swan-egg; the leaves of the latter, too, fall, it is said, much sooner than those of the former.

On walls, in different proper aspects, the following sorts of winter-pears have, it is said, been recommended to be planted: the cressanne, the colmar, the boncretien d'hyver, the chaumontelle, and some others, which are certainly excellent pears, but that some of them are *fly*-bearers, and others do not ripen well in these parts, except in the most favourable situations. Some have found the four following sorts particularly useful on walls, especially in high situations in those northern parts of the country where the other finer sorts do not ripen in a proper manner: the green yair, muirfowl-egg, swan-egg, and winter achan. But it is noticed, that the second and the last of these sorts of pears, when planted as standards, produce not only better crops, but fruit of a higher flavour. Many other sorts are mentioned by different writers as very good winter-pears for the purpose of cultivation in these and other places; as may be seen in the above useful paper.

WINTER-Proud, in *Agriculture*, a term applied provincially to such winter-wheat, or other crop, as puts on a more green and luxuriant growth and appearance than it is able to maintain and support in the following summer season; or in which the tillering shoots, branches, or ramifications of the seed-grain, become too numerous to be nourished and brought to maturity in consequence of the previous over-exertion of the soil or land. In these cases, the crops decline during the spring and summer months, and at the harvest time yield imperfectly, falling much below the quantity afforded by such crops as had a more backward appearance in the winter season.

It is of course always of advantage to have these sorts of crops in rather a backward state in the winter period of the year.

WINTER-Quarters. See **QUARTERS**.

WINTER-Rig, among *Husbandmen*, signifies to fallow or till the land in winter.

WINTER-Solstice. See **SOLSTICE**.

WINTERA, in *Botany*, is so called in memory of the companion of sir Francis Drake, captain William Winter, who brought the bark, of the first species, from the straits of Magellan in 1579, and introduced it to the knowledge of European physicians, as a valuable tonic, more especially useful in the scurvy. Linnæus, meaning to commemorate this discovery, established a genus by the name of *Winterana*, G. Pl. 238, the bark of which he conceived to be what captain Winter introduced. But the Linnæan plant is the *Canella alba*, to the fructification of which alone the description applies. Browne had already founded this genus, by the name of **CANELLA**, (see that article,) and Swartz, as well as Murray, have confirmed it. Meanwhile Forster, having found and investigated the fructification of the Winter's-bark tree, described it by the name of *Drimys*, alluding to its hot and pungent flavour. This is retained by the younger Linnæus in his *Supplementum*, with a remark properly distinguishing it from the *Canella alba*, though his father, like prof. Bergius, *Mat. Med.* v. 1. 381, had confounded them. Finally Murray, in *Linn. Syst. Veg. ed.* 14, aware of these various errors and misconceptions, very properly establishes Browne's genus, by its right denomination, *Canella*, and restores Winter's name to the plant to which it properly belongs, and with which Linnæus intended to associate it. Murray, however, prefers *Wintera* to *Winterana*, which is the more judicious, as his genus is not really the *Winterana* of Linnæus. The name he has chosen is now,

except by an accidental mistake of De Candolle in chronology, universally adopted. Perhaps *Winteria* would have been better; but we refrain from embroiling the subject with any further alteration, of what has received the sanction of such men as Murray and Schreber.—Murr. in Linn. Syst. Veg. ed. 14. 507. Forst. Prodr. 86. Schreb. Gen. 368. Willd. Sp. Pl. v. 2. 1239. Mart. Mill. Dict. v. 4. (Drimys; Forst. Nov. Gen. t. 42. G. Forst. Nov. Act. Upf. v. 3. 181. Linn. Suppl. 43. Lamarck Illustr. t. 494. De Cand. Syst. v. 1. 442. Drymis; Juss. 280. Lamarck Dict. v. 2. 330.)—Class and order, *Polyandria Tetragynia*. Nat. Ord. *Magnolia*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, splitting into two or three segments. Cor. Petals six, or more, ovate, spreading. Stam. Filaments numerous, shorter than the corolla, dilated upwards; anthers terminal, of two lateral ovate cells, separate at the base, converging at their points. Pist. Germens four to eight, crowded, obovate; styles none; stigmas depressed, flat. Peric. Berries four to eight, ovate, somewhat triangular. Seeds several, disposed in two rows.

Ess. Ch. Calyx splitting unequally. Petals numerous. Stamens club-shaped, with terminal two-lobed anthers. Styles none. Berries superior, aggregate. Seeds several, in a double row.

Obf. Willdenow copies what we suspect may be a casual error of the younger Linnæus, *germina clavata*, for *flamina clavata*. De Candolle, who describes two new species, first gave a correct account of the arrangement of the seeds, an important circumstance in this natural order. His observations, confirming those of Linnæus, shew the petals to be indeterminate in number. Possibly the line is not drawn distinctly between them and the *stamens*, of which *Nymphaea* affords another instance, so that an inner series of smaller petals may occasionally occur.

1. *W. aromatica*. Official Winter's-bark. Murray n. 1. Willd. n. 1. Mart. n. 1. Forst. Pl. Magell. 24. t. 7. Comm. Goett. v. 9. 34. t. 7. Soland. in Med. Obf. and Enq. v. 5. 41. t. 1. Woodv. Med. Bot. t. 257. (Drimys Winteri; Forst. Act. Upf. v. 3. 181. Linn. Suppl. 269. Winteranus cortex; Cluf. Exot. 75. Dale Pharmac. 324. Laurifolia magellanica, cortice acri; Bauh. Pin. 461. "Periclymenum rectum, foliis laurinis, cortice aromatico acri; Sloane in Phil. Transf. v. 17. 923. t. 1. f. 1, 2.")—Leaves elliptical, obtuse, coriaceous. Flower-stalks aggregate, terminal. Pistils about four.—Native of the country on both sides of the straits of Magellan, in valleys exposed to the sun, where it was first observed by captain Winter, and has since been found by several following navigators, but no one has brought living plants or seeds to Europe. This is a tree of considerable size, often 50 feet high, with twisted knotty branches, and a thick rugged bark, of an aromatic smell, and pungent permanent flavour. This bark is not much used in practice at present, there being many drugs of equal, or superior, powers; as the *Canella alba*, which has taken its place, and caused the botanical mistake above-mentioned. (See **WINTER'S BARK**.) The leaves are alternate, crowded about the ends of the branches, ever-green, two or three inches long, and one and a half wide, thick and rigid, entire, somewhat revolute, with a stout midrib, and scarcely visible veins, very smooth on both sides; somewhat glaucous, but not invariably or permanently so, beneath. Footstalks broad and thick, smooth, half or three-quarters of an inch long. Stipules none. Flower-stalks at the ends of the branches, two or three together, simple or three-cleft, smooth, not half the length of the leaves, accompanied at their base by several ovate, pale, deciduous bractes. Flowers smaller

smaller than a hawthorn blossom, white. *Calyx* reddish, unequally three-lobed. *Berries* from three to six, each with four triangular *seeds*. By the above synonyms to this species it appears, that even G. Forster, who with his father established the genus and unexceptionable name of *Drimys*, gave way to those eminent botanists who wished to retain the memory of the original discoverer. Indeed the name of Winter may claim even a right of priority, though a mistake attended its commemoration and publication by Linnæus, in his Gen. Pl. We trust our amiable friend M. De Candolle will forgive our not joining with him, in overturning what has been finally settled, with the approbation of all the world. If chronology is to be our absolute guide, without attention to sense, or expediency, the nomenclature of botany must relapse into its pristine barbarism, and in this case Bauhin's name *Laurifolia* should have been adopted. Even on this ground, weak as it is, we can however defend the name we have retained; for Clusius's *Winteranus cortex*, erroneously printed *Cortex Winteranus* by De Candolle, may be considered as the first commemoration of captain Winter, being the first publication of any thing relating to the genus in question.

2. *W. grandensis*. New Granada Winter's-bark. Murr. n. 2. Willd. n. 2. Mart. n. 2. "Humb. et Bonpl. Pl. Æquinox. v. 1. 205. t. 58. Lozano in Sem. Nov. Gran. for 1809, 180." (*Drimys grandensis*; Linn. Suppl. 269. De Cand. n. 3.)—Leaves elliptic-lanceolate, obtuse. Flower-stalks axillary, solitary. Pistils eight.—Sent by Mutis from New Granada. It grows on the most lofty mountains of that country, Quito, &c. The tree is 18 or 20 feet high, with round branches, more straight, and less rugged, than the foregoing. *Leaves* four or five inches long, and near one inch and a half broad, obtuse, not acute, scarcely revolute, perfectly smooth; very glaucous beneath, like those of *Magnolia glauca*, the longer-leaved variety of which they greatly resemble. *Footstalks* smooth, an inch long. *Flower-stalks* sometimes nearly the length of the leaves, always half as long, simple, divided, or three-cleft. *Flowers* twice the size of *W. aromatica*, with about 12 petals, and a deeply three-cleft calyx. *Berries* six or eight, obovate, sometimes confluent, each with from four to six seeds. The bark is aromatic, like the former. The younger Linnæus imagined this to be a variety of that species, caused by a warmer climate. They are indeed more nearly related than appears at first sight, and yet we can scarcely think they belong to one species, though well aware that the leaves, in this natural order, are liable to vary considerably in shape; witness the *Magnolia* just mentioned, if more than one species be not confounded under that name.

3. *W. chilensis*. Chili Winter's-bark. (*Drimys chilensis*; De Cand. n. 4.)—Leaves oblong-obovate; glaucous beneath. Flower-stalks either aggregate or compound, axillary. Pistils five or six.—Gathered by Dombey, in marshy situations in Chili. A tall shrub, with a very aromatic bark, and round branches. *Leaves* nearly obovate, coriaceous, very smooth, tapering at the base, on short stalks, resembling the foliage of *Magnolia glauca*. *Flower-stalks* axillary; sometimes very short, bearing an umbel of four or five elongated simple stalks; sometimes four or five simple ones all together, each an inch long at most, single-flowered. *Calyx* in two or three ovate blunt divisions, not soon deciduous, and perhaps lasting till the fruit is ripe. *Petals* fix to nine, oblong, bluntish, twice the length of the calyx. *Stamens* very short. *Germens* five or six, ovate, crowded, on a small globose receptacle. *Berries* oval, rather compressed, obtuse. De Candolle.

4. *W. mexicana*. Mexican Winter's-bark. (*Drimys mexicana*; De Cand. n. 5. "Moq. et Seffé Pl. Mex. ined. t. . .")—Leaves oblong-lanceolate, pointed at each end. Flower-stalks elongated, umbellate, four-flowered. Petals twenty to twenty-four, acute. Germens four.—Native of Mexico. A shrub, with round branches, terminating in a sharp bud, as in the *Magnolia*. *Leaves* stalked, tapering at each end. *Common flower-stalks* an inch, or an inch and a half long, divided at the top into an umbel of four long, single-flowered, *partial stalks*. *Calyx* divided, permanent, concave. *Petals* white, spreading, oblong, in a double row. *Stamens* very short. *Berries* four, or, from occasional abortion, only two or three, obovate, tapering at the base, of a blueish-violet colour. De Candolle from a coloured drawing.

5. *W. axillaris*. Small-flowered Winter's-bark. Forst. Prodr. 42. Willd. n. 3. Mart. n. 3. (*Drimys axillaris*; Linn. Suppl. 270. Forst. Act. Upf. v. 3. 182. De Cand. n. 1. Lamarck f. 2, copied from Forst. Nov. Gen. t. 42. f. a—l.)—Leaves obovate, pointed, reticulated with veins. Flower-stalks simple, aggregate, thread-shaped. *Calyx* orbicular, lobed, reflexed.—Native of woods in New Zealand. A tree, with round branches, rough to the touch, but not warty. *Leaves* on stalks rather above half an inch long, broadly obovate, tapering to a bluntish point, smooth, more thin and membranous than in any of the other species, copiously reticulated with innumerable veins, not observable in any of those; their length three or four inches, breadth two; their under side glaucous when young only. *Flower-stalks* two or three together, seldom solitary, from the bosoms of most of the leaves, simple, very slender, each bearing a small green flower. *Calyx* discoid, soon reflexed, about a line broad, splitting into two principal, and two smaller, lobes, not differing in any particular respect from the divisions of the calyx of the other species, though Forster's figure has misled De Candolle to suppose otherwise. *Petals* six, oblong, flat, equal, four times the length of the calyx. *Stamens* about sixteen. *Germens* four, turbinate, all perfectly and evidently distinct, in the numerous flowers of the Linnæan specimen; so that Forster might well wonder how the younger Linnæus, who had this very specimen before him, could make a "solitary pistil" a part of the specific character. *Stigmas* dilated, peltate, terminal. *Berries* four, globose, black, with a tawny pulp, lodging four ovate, acute, somewhat triangular, gibbous seeds. The flavour of the whole plant, especially of the bark, is extremely acrid and pungent. G. Forster.

WINTERANA. See CANELLA, and WINTERA supra.

WINTERBERG, in Geography, a town of the duchy of Westphalia; 37 miles S. of Paderborn. N. lat. 51° 11'. E. long. 8° 39'.

WINTERBERG, or Winberg, a town of Bohemia, in the circle of Prachatitz; 10 miles W. of Prachatitz. N. lat. 49° 2'. E. long. 13° 39'.

WINTERBURG, a town of France, in the department of the Rhine and Moselle; 10 miles W.N.W. of Creutznach.

WINTERHAM, a place in Virginia, where black-lead is found; 30 miles N. of Richmond.

WINTERHAUSEN, a town of the duchy of Wurzburg, on the Maine; 4 miles S. of Wurzburg.

WINTERINGHAM, a town of England, in the county of Lincoln; 166 miles N. of London.

WINTERTHUR, a town of Switzerland, in the canton of Zurich. This was formerly an imperial town. In the year 1467, it was mortgaged to the canton of Zurich, and by subsequent treaties entirely ceded, since which Winterthur

thur has acknowledged Zurich for its sovereign. It is governed, however, by a magistracy and police of its own. The government is aristocratical; the supreme power, in all things not interfering with the claims of Zurich, residing in the Great and Little council, in all criminal proceedings these two tribunals unite, and pass sentence of death without appeal. In civil causes, an appeal lies from the Little to the Great council. In all cases respecting the burghers, appeals may be carried from the town-court to the council of magistracy, and no farther; but if either of the parties be a foreigner, an appeal lies from the council to the senate of Zurich. A bailiff from this latter place likewise resides here, but without any authority over the town, excepting that of assisting at the ceremony of an annual homage paid to Zurich by the burghers on St. Alban's day. In case of a war, Winterthur furnishes Zurich with 200 men, either burghers or dependents, but to serve under its own colours. Except in the articles of silk manufacture, and the establishment of a printing-press so profitable to Zurich, the commerce of Winterthur is under no restraint. The principal manufactures are, muslin, printed cottons, and cloth: it has some vitriol works; and the earthen-ware made here, particularly the white, together with its painted stoves, are in great repute for their beauty and durability. The town is small, and the inhabitants, who are about 2000, are very industrious. The schools are well endowed and regulated. Ober Winterthur, or Upper Winterthur, is a small village near the town, on the high road leading to Frauenfeld, on the site of the ancient Vitodurum, which was a Roman station. Here are found the foundations of ancient walls and numerous Roman coins and medals. The castle of Kyburgh, seated on an eminence overlooking Winterthur, is a picturesque object; 14 miles N.E. of Zurich.

WINTERTON, a town of England, in Lincolnshire; 9 miles N.N.W. of Glanford Brigs.—Also, a town of England, in the county of Norfolk, near the coast. The market is discontinued; 7 miles N. of Yarmouth.

WINTERTON *Nefs*, a cape on the E. coast of the county of Norfolk, on which is a light-house; 10 miles N. of Yarmouth. N. lat. $52^{\circ} 44'$. E. long. $1^{\circ} 41'$.

WINTFELDEN, a town of France, in the department of the Upper Rhine; 10 miles S.W. of Colmar.

WINTHAG, a town of Austria; 6 miles N.E. of Freystadt.

WINTHROP, a post-town of the province of Maine, in the county of Kennebeck, with 1444 inhabitants; 57 miles N. of Portland.

WINTHROP'S Bay, a bay on the N. coast of Antigua.

WINTON, a county of United America, in the state of South Carolina.—Also, a post-town of North Carolina; 30 miles E. of Halifax.

WINTONLÆ ROTULUS. See ROTULUS.

WINTZENBERG, in *Geography*, a town of Silesia, in the principality of Neisse; 5 miles S.E. of Grotkau.

WINTZENHEIM, a town of France, in the department of the Upper Rhine; 3 miles W. of Colmar.

WINTZIG, a town of Silesia, in the principality of Wohlau; 9 miles E.N.E. of Steinau. N. lat. $51^{\circ} 27'$. E. long. $16^{\circ} 36'$.

WINWEÏLEK, a town of France, in the department of Mont Tonnerre; 24 miles N.E. of Deux Ponts.

WINWOOD, Sir RALPH, in *Biography*, a statesman in the reign of James I., was born at Aynho in Northamptonshire, about the year 1564, educated at St. John's college, Oxford, and having passed through several stages of preferment, was chosen professor of the university in 1592. After having sustained several diplomatic characters and missions,

he was made secretary of state in 1614, which office he occupied till his death in 1617. "He was married, and left one son. Sir Ralph was an accomplished gentleman, well acquainted with business, and particularly conversant with commercial and military affairs." A work, intitled "Memorials of Affairs of State in the Reign of Queen Elizabeth and King James I., collected chiefly from the Original Papers of the Right Honourable Sir Ralph Winwood, Knt. &c. &c." was published in 1725 by Edmund Sawyer, esq. in 3 vols. fol., and contained a valuable record of the political transactions of those times. Biog. Brit.

WINYAH, in *Geography*, a county of South Carolina.

WINZAH HARBOUR, a bay on the coast of South Carolina, a little to the N. of the mouth of the Santee. N. lat. $33^{\circ} 12'$.

WINZER, a town of Bavaria, on the Danube; 9 miles S.S.E. of Deckendorf.

WIOCHIST, among the *Indian Natives of Virginia*, is their priest, who is also generally their physician; and is the person in the greatest honour amongst them, next to their king, or great war-captain. Phil. Transf. N^o 454. sect. 1.

WIOGRODEK, in *Geography*, a town of Poland, in Volhynia; 14 miles E.S.E. of Kreminek.

WIP, a town of Prussia, on the Curisch Haff; 23 miles S.W. of Tilsit.

WIPACH, a town of the duchy of Carniola; 5 miles S. of Hydria.

WIPE, a town of Prussia, in the province of Smaland; 28 miles N.E. of Königsberg.—Also, a river of Prussia, which runs into the Curisch Haff, 10 miles E.N.E. of Labiau.

WIPFELN, a town of the duchy of Wurzburg; 5 miles N.N.W. of Volkach.

WIPPELSPACH, a town of the duchy of Stiria; 17 miles S.W. of Voitsberg.

WIPPER, a river of Germany, which rises in the county of Mark, about 6 miles S.S.W. of Lunschede, passes by Wipperfurt, Elberfeld, Solingen, &c. and runs into the Rhine, between Cologn and Zons.—Also, a river of Thuringia, which rises 2 miles N. of Dingelstadt, and runs into the Unstrutt, 4 miles N.E. of Kindelbrucken.—Also, a river of Pomerania, which runs into the Baltic below Rugerwalde.—Also, a river of Saxony, which runs into the Saal, near Bernberg.

WIPPERAU, a river of Westphalia, which runs into the Ilmenau, near Ultzen.

WIPPERFURT, a town of the duchy of Berg; 27 miles S.E. of Duffeldorf. N. lat. $51^{\circ} 5'$. E. long. $7^{\circ} 27'$.

WIPPINGEN, a town of Switzerland, in the canton of Friburg; 12 miles S.S.W. of Friburg.

WIPRA, a town of Westphalia, in the county of Mansfeld, on the Wipper; 10 miles W.N.W. of Eifzleben. N. lat. $51^{\circ} 30'$. E. long. $11^{\circ} 30'$.

WIRBEN, a town of Westphalia, late in the Old Mark of Brandenburg, on the left side of the Elbe; 12 miles N. of Stendal.

WIRBENTHAL. See WURBENTHAL.

WIRDOIS, a town of Sweden, in North Finland; 65 miles N.N.E. of Biorneborg.

WIRE, in the *Mechanic Arts*, is a very useful preparation of different metals, in form of a regular and even thread, which can be obtained in very great lengths, and of any required size or shape.

Wire is made of any ductile metal, as platina, gold, silver, copper, brass, zinc, iron, or steel. The process of making wire

wire consists in drawing the piece of metal through a hole in a plate of steel, by which means the metal is rendered of an equal size, and either round or of any other figure corresponding with the figure of the hole in the draw-plate; the metal is thus reduced in size, and at the same time is lengthened in proportion. From the great regularity of wire, and from its toughness and ductility, it is extremely useful to all artists who work in metal.

The operation is called wire-drawing, and the plate of steel a draw-plate. The machine by which the wire is drawn is called a draw-bench.

The common draw-bench is of a simple structure. A strong plank of wood is fixed on legs, like a stool or bench, *fig. 1. Plate Wire.* At one end is a roller or axis, *A*, fixed in an horizontal position, so that it can be turned round by means of four levers, *B B*, fixed like radii on the end of the axis of the roller. If the resistance is great, the workman applies both his hands and his feet to the levers, to turn them round in the same manner as for a rolling-press. It is usual to have a strong strap, or chain, *C*, to wrap and wind up round the roller; and at the end of it a pair of pincers, *D*, are linked: these take hold of the end of the piece of metal, and draw it through the hole in the draw-plate *E*, which is lodged against two strong iron pins, *aa*, fixed in the bench, and standing up perpendicularly, so that the plate bears against them.

The pincers are shewn in *fig. 2.* They are adapted to bite the end of the wire; and the inside of the jaws, *dd*, are cut with teeth like a file, that they may hold the metal very tight. The opposite ends of the handles are bent in form of hooks at *ee*; and a triangular link of iron *f*, which is fastened to the end of the strap or chain *C*, embraces both hooks *ee*, and from its triangular figure, it tends to approach the two hooks at the ends of the tongs together: by these means, the strain of drawing the wire closes the pincers, and makes them bite more forcibly in proportion as the wire makes a greater resistance, so that they rarely let the wire slip.

The draw-plate, *figs. 3 and 4*, is a thick plate of steel, with holes made through it of various sizes, and in a regular gradation from the largest to the smallest. The holes are made large on that side where the wire enters, and they diminish with a regular taper to the other side; the goodness of the draw-plate is an object of the first importance. The different holes must diminish by very small gradations, or there will be danger of breaking the wire by forcing it too much at once.

In some draw-benches a rack and pinion are employed, instead of a strap or chain; and a train of wheel-work may be used like that of a crane to obtain a sufficient power. (See *fig. 5.*) If the workman turns the machine by a winch or handle, it is preferable to four levers, because the motion is more regular; this is of importance for some purposes. Suppose a piece of elastic metal is forcibly drawn through a hole in a plate with a tolerably quick motion, it will be compressed at the moment of passing through the hole; but after it quits the hole, the metal will expand a little. When it is drawn very slowly, this effect will not take place; for if the compression is continued long enough it becomes permanent: hence, if a piece of large wire be drawn with an irregular motion, first quicker, and then slower, it will be sensibly larger at all the parts which pass quickly through the hole, and smaller where it is drawn slowly: if the motion is suspended for a few seconds, that part of the wire which remains in the hole will have a ring or indentation round it. This is most obvious in drawing hollow tubes, or copper-wire, which is plated over with gold or silver.

In the machine which is used for drawing strong pieces

of metal, and for the very largest, the roller is usually placed in a vertical position, like a capstan, with four levers, at which several men push, whilst they walk round in a circle to turn the capstan, and wind up the chain which draws the wire through the draw-plate.

A powerful machine of this kind is described in our article *PIPES*, for drawing lead-pipe through a steel plate.

We have seen a very powerful wire-drawing machine used for forming large hollow tubes of brass or copper, on which the power to draw the tube was obtained by a screw, like that of a press. This screw was turned by a train of wheel-work, with a fly-wheel to regulate the motion.

Another plan, which is perhaps the best mode for a very powerful drawing-machine, is to apply the force of the hydrostatic machine originally invented by Pascal, and revived by the late Mr. Bramah. (See *MACHINE*, and *PRESS.*) By this means, very large wires for piston-rods of steam-engines, and other similar pieces, may be rendered straight and true with little expence.

All these machines are confined to draw pieces of metal, which are only a few feet in length, that is, the length of the bench. But when the metal by repeated drawing becomes lengthened into a regular wire, if it is required to reduce it to a still smaller size, it must be drawn through succeeding plates, by wrapping the wire itself upon the roller or barrel, instead of employing a long chain. This method is not applicable at first, because a thick bar of iron could not be made to bend easily round a roller; but when the wire becomes small and flexible, it can be practised very advantageously, and admits of drawing a very great length of wire by a small and commodious machine.

The common wire-mills used in France do not, however, employ a roller or windlafs, but the pincers are attached to a lever, which draws them backwards and forwards alternately by the power of the water-wheel.

The pincers are so constructed, that the jaws open when they move towards the draw-plate, and release themselves from the wire; but when the pincers are drawn back from the draw-plate, the link causes the pincers to close and bite the wire with such force, that they will draw it through the plate.

A machine of this kind is shewn in *fig. 7.* of the plate. The base of the machine is a very strong log of timber *R*; one end of it is cut open to receive a wooden lever *A B*, which moves round an iron pin or bolt *n*, as a centre of motion; this lever is shaped like the letter *L*. To the upright arm *A* of this lever, an iron link *C* is jointed, and the other end of this link is formed like a ring, to receive the handles of the pincers *D*. The pincers are supported upon a plate of iron *d*, which is placed in an inclined position, and there is a groove in the plate, into which the end of the pin or joint of the pincers is received, and they are by that means guided in their motion backwards and forwards: *aa* are the pins which support the draw-plate *E*; there are four of them, and the plate is fastened between them by wedges.

The end *B* of the lever is operated upon by cogs fixed on the axis of the water-wheel, which, as it turns round, depresses the end *B* of the lever; and the end *A* pulls the pincers back, and draws the wire through the draw-plate; but when the cogs quit the end of the lever, it is returned by means of a rope fastened to the end of *B*, and going up to a strong wooden pole fixed on the roof of the building; and it acts as a spring. When the pincers return, they open to release the wire, and slide down the inclined plate *d* by their own weight, till they are near the draw-plate; the wire being all the time included between the jaws, though they

they do not bite. The next cog which seizes the end of the lever draws back the pincers, which immediately close upon the wire, and draw it through the plate.

A wire-mill usually contains three such machines of different sizes: the largest only draws two inches of the wire at each stroke, and makes about forty-eight strokes in a minute; the second machine, four inches; and the third, five inches. This works quicker than the other two, and makes sixty-four strokes *per* minute. This is a simple machine, but very defective, for much time is lost in the returning of the pincers; they sometimes fail to take good hold of the wire, and they always make deep marks upon the wire at every place where they bite, which are not more than two inches distance in the great wire, and five inches in the smaller.

Fine wire is always made from large wire, by reducing it and lengthening it out by repeated drawings. The large wire is usually manufactured at the wire-mills in the country, and some part of it is reduced to small wire at the same establishments, but more commonly the large wire is bought by those who have occasion for it, and they reduce it by drawing until it becomes as small as it is wanted.

The hand-machine for this purpose, represented in *fig. 8*, is extremely simple. *A* is the roller on which the wire is wound up; it turns round upon a vertical pin, fixed in the bench *R*, and to the upper end a handle *B* is fixed, for the workman to turn it round; *E* is the draw-plate, and *a a* the pins against which it rests. The wire which is to be drawn is put upon a small circular reel *F*, which turns round upon a vertical pin; this pin is sometimes fixed in the table, or otherwise in a small cask containing starch-water, or beer which has become acid. The use of this is to loosen the oxyd from the surface of the wire, for it is necessary to anneal or soften the wire very frequently, by putting it in the fire, and this produces a black coat of oxyd on the surface, which will be removed when the wire is again drawn through the plate, and the wire will come out bright and clean. The removal of this oxyd will be facilitated by some slightly corrosive menstruum.

Fig. 9. is a very simple and complete wire-drawing machine, to draw three wires at once. *A R* are two rollers or barrels with cog-wheels, *T V*, on the ends of their axis, which wheels are engaged together. *S* is a pinion, which is turned round by means of a handle *B*, and gives motion to the wheels *T V*. Both these wheels are fitted upon round parts of the axis of their respective rollers, so as to slip or turn freely round upon the same; but a square is formed on the axis outside of the wheel, and a clutch or catch, *t* or *v*, is fitted on this square part, so as to turn always round with the axis. The catch is at liberty to slide upon the axis in the direction of its length, by means of a lever *W*, which operates upon both catches at once. When either of them is pushed back in contact with the wheel, it intercepts two studs which project from the face of the wheel, and then compels the axis and roller to turn round with the wheel; but when the catch is drawn away from the wheel, then the wheel will flap round upon its axis, without communicating any motion. By means of the lever *W*, only one wheel can be engaged at once, and the other must be free. The draw-plate *E* is firmly fixed between the two rollers, and it has a great many holes; the rollers are long enough to receive three wires at the same time. Each roller has a groove in it parallel to the axis, into which a bar of metal is fitted, and will exactly fill it up. When the wires are introduced through the holes in the plate, the ends are laid across this groove; the bar is then put in and fastened by a simple contrivance, and it

fastens the ends of the wires beneath it, so that they become attached to the roller; then by turning the handle *B* round, the two wheels are put in motion in contrary directions; and that wheel which is connected with its axle by its catch, will turn its barrel round, and wind up the wires so as to draw them through the plate *E*. The other roller being at the same time detached, its wheel is at liberty to turn round in a contrary direction to the wheel, as fast as the wires are drawn off from it. When the whole length of the wires has been drawn through the plate, they are detached from the roller, the ends introduced through smaller holes in the plate, and fastened again to the roller; then the lever *W* is shifted, to disengage that wheel which operated before, and engage the other. This being done, the rollers will be turned in an opposite direction, and will wind back the wires, although the handle *B* is turned the same way round.

After the wire has been then drawn three or four times, the metal becomes so hard and fibrous, that it would not draw any more without breaking; it therefore requires to be heated in the fire to restore its ductility; for this purpose it must be taken off the barrels. A roller *M* is provided to wind the wire upon and draw it off from the barrel; this roller is turned round by a handle *m*, fixed on the extremity of its axis; and the wire which is wound upon it in a coil is slipped off sideways. This machine is well adapted to be worked by a mill, because the handle may always be turned the same way.

Fig. 10. represents the machine used at the wire-mills for reducing the wire which is to be used for musical instruments, or for making cards for wool and cotton. The rollers *A* are situated in a vertical position, being fitted on the tops of iron spindles, which are sustained in a vertical position by bearings in the frame of the table or bench. These spindles are kept in continual motion by wheel-work situated beneath the bench, but the spindles are round, so that the rollers *A* are not turned with the spindles, unless any one of the rollers is lifted up upon the spindle. A cross-bar, which is fixed on the top of the spindle, then engages with two projecting knobs fixed in the roller, within a hollow recess made at the top of it, and turns the roller round. The draw-plate *E* is supported by two pins, as before described; and the wire which is to be drawn is wound on a reel, which is put into a cask of stale-beer grounds, or starch-water. The end of the wire, which is put through the draw-plate, is made fast to the roller, which does not turn round as long as it is dropped down upon the spindle; but when all is ready to begin drawing, the roller must be lifted up, and the clutch at the top of the spindle will engage with the two knobs within the hollow at the top of the roller. This puts it in motion, and draws the wire through the draw-plate. The strain of drawing is sufficient to keep the roller up upon the spindle; but as soon as the whole of the wire is drawn through the plate, the resistance ceases, and the roller drops down on its spindle, and becomes disengaged until the workman puts it again in action.

Manufacture of Iron Wire.—Iron is a very ductile metal, but requires a careful treatment in the process of wire-drawing, because it becomes very hard and brittle when the fibres are greatly compressed by repeated drawing. Its ductility must then be restored by heating the wire to redness; this is called annealing: it renders the wire soft, and it will then draw finer and longer; but it will soon require annealing again, and so on.

The iron which is selected for wire-drawing must be of good quality, to bear the requisite extension without breaking. It must be of an uniform substance, without any grains

of hard or soft parts. The softest iron is not always found the best, as it will diminish by the strain of drawing it through the holes alone: and to obviate this, the workman must draw such iron through a greater number of holes to obtain the required extension.

The iron is wrought at the tilt-mills from square bars into round rods of a proper size to commence drawing. The operation of tilting is nearly the same as *tilting of steel*. (See that article.) The tilt-hammer for a wire-work generally makes twenty strokes *per* minute, and weighs about fifty pounds. There is also a larger hammer worked by the same mill, which strikes about 130 times *per* minute, and weighs 100 pounds. This hammer is only used for the first preparation of the iron, or for welding a faggot of small bars together, in order to give the iron a better quality by a preparation similar to the German steel. To draw out the iron bars into rods of a proper size to begin drawing, the workman heats six or eight inches of the end of a large bar, which comes from the great forge where the iron is made, and when properly heated he works it regularly under the small tilt, until it is drawn out to a small and regular round rod of five or six feet in length. A good workman can thus draw out two hundred weight of iron in a day, or an ordinary workman one and a half hundred weight. The loss of metal in the operation is near 6 *per cent.* by weight.

The small rod, before it is cold, is taken by another workman, who straightens the rod with a hammer upon an anvil, then cuts it off, and places the end of the great bar again in the forge. This same workman also superintends the heating of the iron, and must be very careful not to overheat it, but to heat the whole regularly.

It is a good practice to pass the iron-rod through a pair of grooved rollers, the grooves of the two rollers being opposite, so as to form a round between them. By these means, the iron may be reduced small, and rendered very true, previously to beginning the drawing. For common wire, the whole reduction may be done by the rolling-mill without a tilt; but the hammer will give a more tenacious quality to the iron than can be obtained by rolling.

A small round bar, thus prepared, must be drawn through a hole in a draw-plate, by a strong machine with a chain, or else by the lever-machine, *fig.* 7. The end of the iron is first reduced, so that it will enter the hole in the draw-plate, and pass through sufficiently for the pincers to take hold. This is done at the forge by a hammer and anvil. By passing through the plate the wire becomes lengthened, in proportion as it is diminished in size. It must then be annealed to soften it, the end pointed anew, and again put through a smaller hole.

The workman who attends the process must study the nature of the iron, and regulate the manner of drawing accordingly. This he does by altering the figure of the hole through which the wire is drawn. The hole must be conical; the smallest part, being that which acts principally on the metal, must be at that side of the plate where the wire comes through. If the taper of the hole is not properly proportioned, the iron will be strained in drawing; for though the machine will force it through, grains of harder metal than the rest of the wire will form themselves, which will occasion the wire to break when it comes to be much reduced. This is particularly the case in soft iron. To avoid this, the hole must be chosen very little smaller than the iron, and must be made with a regular taper. It must be well supplied with grease, to diminish as much as possible the friction; and the motion of the draught must be regulated according as the metal will bear it.

Much depends upon the quality of the draw-plate; although the metal of the plate is sufficiently hard to draw the wire, it will not resist the blow of a hard steel hammer and punch. The punch is driven into the hole from behind, until it enlarges it to the required size and figure. In the operation of drawing, the hole becomes gradually enlarged, and that in a greater degree at the smallest end of the hole, so that it becomes nearer to a cylinder. To rectify this, the punch must be applied, or the wire would not pass easily; that is, if the same degree of reduction in the size of the wire was attempted, it would break or strain the wire, if the hole was cylindrical, although it would pass through a regular taper hole. The hole sometimes wears irregularly, and loses its circular figure. In this case, the plate is hammered around the small end of the hole, and the hole is thereby reduced. The punch is then driven in, to enlarge it again to the required size: sometimes the punch is introduced at the small end, and then at the large end, as it may be required to form the hole. In all cases, the punch must be driven very gently; and after every stroke of the hammer it must be loosened in the hole, and turned round before another blow is struck, and without this precaution it would fix fast in the hole.

The French draw-plates are the most esteemed; and, in time of war, a good French draw-plate has been sold for its weight in silver. M. Du Hamel, in *Les Arts et Metiers*, vol. xv. gives the following account of the process of making the draw-plates for the large iron-wire.

A band of iron is forged of two inches broad and one inch thick. This is prepared at the great forge. About a foot in length is cut off, and heated to redness in a fire of charcoal. It is then beaten on one side with a hammer, so as to work all the surface into furrows or grooves, in order that it may retain the substance called the *potin*, which is to be welded upon one side of the iron, to form the hard matter on which the holes are to be pierced. This *potin* is nothing but fragments of old cast-iron pots; but those pots which have been worn out by the continued action of fire are not good: the fragments of a new pot which has not been on the fire are better.

The workman breaks these pieces of pots on his anvil, and mixes the pieces with charcoal of white wood. He puts this in the forge, and heats it till it is melted into a sort of paste; and to purify it he repeats the fusion ten or twelve times, and each time he takes it with the tongs to dip it in water. M. Du Hamel says, this is to render the matter more easy to break into pieces.

By these repeated fusions with charcoal, the cast iron is changed, and its qualities approach those of steel, but far from becoming brittle; it will yield to the blows of the hammer and to the punch, which is used to enlarge the holes. The bar of iron which is to make the draw-plate is covered with a layer of pieces of the *potin*, or cast iron, thus prepared. It is applied on the side which is furrowed, and should occupy about half an inch in thickness. The whole is then wrapped up in a coarse cloth, which has been dipped in clay and water mixed up as thick as cream, and is put into the forge. The *potin* is more fusible than the forged iron, so that it will melt. The plate is withdrawn from the fire occasionally, and hammered very gently upon the *potin*, to weld and in some measure amalgamate it with the iron, which cannot be done at once; but it must be repeatedly heated, and worked until the *potin* fixes to the iron. The workman then throws dry powdered clay upon it, in order, they say, to soften the *potin*.

The union being complete, the plate is again heated, and forged by two workmen, who draw out the plate of one

foot to a length of two feet, and give it the form it is to have. It is well known that cast iron cannot be worked at the forge without breaking under the hammer; but in the present instance, it is alloyed with the iron-bar, and is drawn out with it. It has also acquired new properties by the repeated fusions with charcoal.

The holes are next pierced whilst the plate is hot. This is done with a well-pointed punch of German steel, applied on that side of the plate which is the iron-bar. It requires four heats in the fire to pierce the holes, and every turn a finer punch is employed, so as to make a taper hole. The makers of draw-plates do not pierce the holes quite through, but leave it to the wire-drawers to do it themselves when the plate is cold, with sharp punches, and then they open the hole to the size they desire; and although this potin is of a very hard substance, the size of the hole may be reduced by gentle blows with a hard hammer, on the flat surface of the plate, round the hole.

A great many holes are made in the same plate; and it is important that they should diminish in size by very imperceptible gradations; so that the workman can always choose a hole suitable for the wire he is to draw, without being obliged to reduce it too much at once.

To ascertain the size of the wire, gauges are used. They are commonly made of a piece of wire bent in zigzag, as shewn in *fig. 11*; and the space between every bend is of a different width; but a better sort is made of a steel-plate, with notches on the edge. (See *fig. 12*. for the standards.) These should be hardened, that they may not be subject to wear.

Fig. 13. is another kind of gauge, which is very accurate. It consists of two straight rules of steel, put together at an angle. The diameter of the wire is indicated by the depth to which it will enter into the angle; the edges of the rulers are divided into equal parts for that purpose, and numbered, to correspond with the different sizes of wire.

The wire manufactory of Messrs. Mouchel, situated at l'Aigle, in the department de l'Orne, is one of the most considerable in France. It furnishes annually, in cards for wool-combing only, an hundred thousand quintals of iron-wire, each 100lbs. A part of this is consumed in France, and the rest is exported to Portugal, Spain, Italy, and even to the shores of the Levant.

They employ the iron manufactured in the departments of l'Orne and La Haute Saone, as being of the best quality. The first produces the best wire for making screws, nails, and pins, as much on account of its hardness as its fine polish, which resembles steel-wire. In this respect, it is superior to the iron of Haute Saone, but from its ductility the latter can now be made extremely fine, and it appears to be most free from heterogeneous particles.

The smelted iron, prepared and hammered, being in a state nearly fit for their purpose, is transported, at a small expence, to l'Aigle, by the rivers and canals. They have a forge to reduce the steel and iron of Normandy, which arrives in large pieces, into small and regular bars.

When the iron is formed into an irregular bar of about a centimetre, near four-tenths of an inch in diameter, they begin to draw it into wire. Although it be already much extended by hammering, it is in the first place passed four times through the drawing-plate; then its molecules become disposed lengthways, and exhibit fibres at their utmost extension. The fibres must be removed by means of heat, which disperses and divides them; and after that the wire may again be reduced three numbers. The fibres which are re-produced by this operation are again removed by heat. The whole process is five times repeated; conse-

quently the wire is passed through fifteen numbers; after which, a single exposure to the fire is sufficient to fit it for passing six others, whereby it is reduced to the thickness of a knitting-needle.

The steel-wire, being much harder, requires to be passed through forty-four numbers, and to be annealed every other time.

The machine which draws the steel-wire must go slower than that which draws the iron; for the first being very hard, and offering more resistance to the drawing-plate, should be pulled out with more care, since the quickness ought to be proportioned to the resistance, and reciprocally; and if they depart from this principle, the results will vary. Thus, for example, the iron of the department de l'Orne, which is more compact than that produced at Haute Saone, if drawn by the same machines, augments in hardness, and is weakened when it is brought to too great a degree of fineness. But this iron, which is very hard, and capable of receiving a very high polish, is to be preferred for certain uses.

In order to anneal the wire, they formerly employed a large and elevated furnace, with bars of cast iron to support the wire in the middle of the flames. It contains seven thousand pounds weight, so contrived as to contain equal portions of each number. They are so arranged that the thickest wires receive the strongest heat; therefore, the whole is equally heated in the same space of time. The operation lasts three hours with a fire well kept up, and it might be imagined that this apparatus was completely adapted to the purpose; but there are imperfections in this method, because it leaves the wire exposed to the contact of the atmospheric air, the oxygen of which seizes it with extreme avidity; whence a considerable quantity of oxyd is occasioned, and also an operation to free it from the scales, which consists of beating the bundles of wire with a wooden hammer wetted with water.

Notwithstanding this precaution, there often remains a portion of oxyd adhering to the surface of the metal, which streaks the draw-plate, or fixes on the wire, and gives it a tarnished appearance, and causes it to break when it is brought to a great degree of fineness. This furnace is only used for the steel-wire, or the iron from l'Orne, which is less liable to change, and besides being harder is not so easily attacked by the oxygen.

In order to diminish the waste that the fire occasions, they have contrived another process, which consists in dipping the bundles of wire into a basin of wet clay before they put them into the furnace; and they are left in the furnace to dry before the fire is lighted, without which precaution the clay would peel off from the iron.

For making wire for cards, M. Mouchel invented another furnace. It is round, and about one metre six decimetres in diameter, and one metre eight decimetres in height, without including its parabolic arch and the chimney above it. The interior is divided by horizontal grates into three stories; the lowest receives the cinders, the second is the fire-place, and into the third or upper place they slide a rouleau of wire, weighing one hundred and fifty kilogrammes, which is inclosed in a space comprised between two cast-iron cylinders, being luted to prevent the admission of air between them. The flames circulate about the outside of the first, and within the interior of the second, which defends the wire from atmospheric air. The diameter of the largest cylinder is about one metre four decimetres, that of the second one metre. Thus the space comprised between them is two decimetres, on an elevation of five decimetres. There must be several pairs of cylinders provided; because whilst one pair

pair is in the furnace another must be prepared to receive a fresh rouleau of wire. They are changed every hour by means of a long iron lever, with which a single man can easily push them in and draw them out again, as the cylinder slides on cast-iron rails.

They are very careful not to open the cylinders immediately on their being drawn out of the fire; for the rouleaus of wire contained in them, being still red, would oxydate quite as much as if they had been heated in the midst of the flames without the least precaution.

The opening contrived for the passage is on the side, and has a door of cast iron, with a groove which winds round the furnace. The fire-place has one something similar to it. That of the ash-hole is vertical, in order that it may be raised to increase the fire at will.

When the iron-wire is reduced to the thickness of a knitting-needle, it is made up in bundles of 125 kilogrammes (275 pounds) each, into a large iron vessel, in order to anneal it sufficiently to be reduced for the last time. This vessel is placed upside-down in the middle of a round furnace, which is so constructed as to sustain burning coals all round it, and of which it consumes 35 kilogrammes (77 pounds) before the operation is completed. The cover must be carefully luted, as the slightest admission of air is sufficient to burn the external surfaces of the wire to an oxyd, which cannot afterwards be reduced.

When one of these vessels is sufficiently heated, it is filled with water, containing three kilogrammes (six pounds and a half) of tartar, and suspended over the flames of the furnace to make it boil. This solution, without attacking the metal, frees it from the grease and the little oxyd that adheres to it. This is the last operation in which the wire is exposed to the fire; and it is then in the proper state for being reduced to the utmost degree of fineness it is capable of sustaining, and will preserve enough of the effect of the annealing to require it no more. But when the natural hardness of the iron varies, this last exposure to the fire should take place in proportion to its thickness. As steel loses its capacity of extension much sooner than iron, it is annealed until it is no thicker than a sewing-needle. The space which is left in the vessel is filled up with charcoal-dust, which prevents it from losing the quality of steel, and preserves the heat long enough to give it the proper degree of pliancy.

As Messrs. Mouchel always use iron and steel of the same manufactory, they have been able to reduce their operations to a general system; and to attain this end, have determined a graduated scale, by which the wire will not be more stretched in the drawing-plate in one number or size than another. The following is the method they contrived, in order to form this scale for the iron-wire. They take a certain quantity of various thicknesses, which has been drawn as fine as the iron would bear. The smallest size is 100,000 metres (109,333 yards) in length to the kilogramme, 2.2 pounds avoirdupois. They note the weight that each might be capable of supporting without breaking. This being expressed by figures, it is easy, by a few interpolations, to express them in a progressive form. This kind of scale has been partly formed by comparing the weight of the different sizes with equal lengths, from which gauges or calibres may be made for the use of the workmen. These gauges are certain guides, which they cannot mistake except through great carelessness. If they had not these guides they would often pass the wire through holes in the drawing-plate that are too large for it, whence it does not acquire the strength it should have in proportion to its thickness, and loses its hardness. They might also pass it through holes

that were too small, which would weaken it, and render it very brittle. In the latter case, it frequently happens that the steel of the drawing-plate, being unable to sustain the force to which it is exposed, will give way, as if the plate were too soft; and the wire will be brittle at the beginning, and soft and too thick at the other extremity.

The greatest part of the fine wire of Messrs. Mouchel's manufactory is drawn by workmen who are dispersed about the country; but they have also a machine which moves twenty-four bobbins in a horizontal direction, which only requires the workman to look after it. It is upon the bobbins that the wire is reduced to the different degrees of thinness desired; therefore, this is the last operation in the art of making iron and steel wire; although it has all requisite qualities given to it in the work-shop of the wire-drawer.

Wire is still incapable of being made into needles and carding-hooks, until it has undergone another operation for dressing or straightening the wire, by which it is made to lose the bend or curve that it acquires on the bobbins.

This work consists in drawing the wire between nails fixed in a piece of wood, and which act to bend the wire, first in one direction, and then in the opposite, in a waving line, of which the waves are at first larger, but decrease gradually, and the last bend of which tends to force the wire into a straight line. The dresser is obliged constantly to adjust the nails, by inclining or raising them with strokes of the hammer. Also for each number of wires the pins must be at different and calculated distances. This requires a workman of intelligence, diligence, and address.

An ingenious instrument is now appropriated to this operation, and removes all difficulty. Six little puppets of very hard steel are substituted for the nails of the ordinary instrument, and are fixed on parallel bars of metal, so jointed together that the movement of them all will be parallel, and the puppets are widened or brought nearer together by screws. The wire is drawn between these puppets in a zigzag or waving line, and the repeated flexures break the sinuosities of the wire. There is a conductor of the wire to the puppets, and another conductor which serves to prevent the wire from being shaken. There are slight grooves at the extremity of the puppets, to give a passage to the wire. A scale sustained by a screw indicates the distance at which the puppets should be placed from each other, to straighten each size of wire. This forms an invariable rule, and the dresser (who may be a child) saves a third of the time which is employed in regulating the nails of the instrument formerly used. There is nothing more to be done but to draw out the wire by means of a wheel, on which he reels it, and then forms it into bundles to be delivered to the consumers.

The steel-wire of France is proper for many purposes. It is brought from Messrs. Mouchel, for making knitting-needles in the English fashion, shoemakers' needles, and other similar articles. It may also be used for needles of all sizes, and even for cards for wool-combing; but as this steel is much more expensive than the iron-wire, it is very seldom used for the latter purpose.

The method of preparing the draw-plates is described by Messrs. Mouchel, and is different from that before described.

For making wire for cards, two sorts of drawing-plates are used, large and small ones. The first, for the sort of wire that we have been describing, is drawn with the pincers, as *fig. 7*, and with the bobbin or roller, which is a cylinder adapted to the axis turned by the water-mill, and is used in preference, to avoid the marks made on the wire by the pincers. The small drawing-plates are used for such wire

as may be drawn by hand. The steel which they employ for these drawing-plates should never vary in quality, except that the smaller plates are made of the finest steel. Several pieces of iron are disposed in the furnace in the form of a box without a lid, their weight being according to the use for which they are intended to be employed.

The workman fills each of these boxes with cast steel, and having covered it over with a luting of clay, it is exposed to a fierce fire until the steel be melted. His art consists in seizing the proper moment to withdraw the plate from the fire: he raises the luting, and blows on it through a tube, in order to drive off all heterogeneous parts, and then amalgamates it with the iron by light blows. After it is cool, he replaces it at the fire, where the fusion again takes place, but to a less degree than before; he afterwards works the steel with light blows of the hammer, to purify and solder it with the iron. This operation is repeated from seven to ten times, according to its quality, which renders it more or less difficult to manage. During this process, a crust forms on the steel, which is detached from it the fifth time of its exposure to the fire, because this crust is composed of an oxydated steel of an inferior quality. It sometimes happens that two and even three of these crusts are formed of about two millimetres, or one-sixteenth of an inch in thickness, which must also be removed.

After all these different fusions, the plate is beaten by a hammer wetted with water, and the proper length, breadth, and thickness, are given to it. When thus prepared, the plates are heated again, in order to be pierced with holes by punches of a conical form; the operation is repeated five or six times, and the punches used each time are progressively smaller. It is of importance that the plate never be heated beyond a cherry-red, because if it receives a higher degree of heat, the steel undergoes an unfavourable change. The plates, when finished, present a very hard material, which nevertheless will yield to the strokes of the punches and the hammer, which they require when the holes become too much enlarged by the frequent passing of the wire through them.

When the plates have been repaired several times, they acquire a degree of hardness, which renders it necessary to anneal them, especially when they pass from one size to another; sometimes they do not acquire the proper quality until they have been annealed several times. Notwithstanding all the precautions which are taken in preparing the plates, the steel still varies a little in hardness, and according to this variation they should be employed for drawing either steel or iron wire; and if the workman who proves them finds that they are too soft for either the steel or iron, they are put aside, to be used by the brass-wire drawers.

A plate that is best adapted for drawing steel-wire is often unfit for the iron; for the long pieces of this latter metal will become smaller at the extremity than at the beginning, because the wire as it is drawn through the plate is insensibly heated, and the adhering parts are swelled, consequently pressed and reduced in size towards the latter end. The plates that are fit for brass are often too soft for iron, and the effect resulting is the reverse of that produced by a plate that is too hard.

The smallest plates which Messrs. Mouchel use are at the least two centimetres, or eight-tenths of an inch in thickness, so that the holes can be made sufficiently deep; for when they are of a less thickness, they will seize the wire too suddenly and injure it. This inconvenience is much felt in manufactories where they continue to use the plates for too long a time, as they become exceedingly thin after frequent repairs. One of Messrs. Mouchel's large plates

reduces 1400 kilogrammes (3080 pounds avoirdupois) from the largest size of wire to No. 6, which is of the thickness of a knitting-needle; 400 kilogrammes (880 pounds) of this number are afterwards reduced in one single small plate to No. 24, which is carding wire; and to finish them, they are passed through twelve times successively.

For the tenacity of iron wire, see IRON.

The first wire-mill in England was set up by a Dutchman at Sheen, near Richmond, in 1663.

Wires are frequently drawn so fine, as to be wrought along with other threads of silk, wool, or hemp: and thus they become a considerable article in the manufactures. See DUCTILITY.

WIRE, Gold. See GOLD-WIRE.

Muschenbroeck records, that an artist of Augsbourg drew a wire of gold so slender, that 500 feet of it weighed only one grain; and Dr. Wollaston, secretary of the Royal Society, has shewn, that a wire of gold may be drawn much finer than this, and that wires of platina may be drawn much more slender, with the utmost facility. Those who draw silver-wire in large quantities for lace and embroidery, sometimes begin with a rod that is about three inches in diameter, and

ultimately obtain wires that are so small as $\frac{1}{100}$ of an inch in

thickness. If in any stage of this process a rod of silver-wire be taken, and a hole be drilled through it longitudinally, having its diameter one-tenth part of that of the rod, and if a wire of pure gold be inserted, so as to fill the hole, it is evident that by continuing to draw the rod, the gold within it will be reduced in diameter exactly in the same proportion as the silver; so that if both be thus drawn out

together till the diameter of the silver is $\frac{1}{500}$ of an inch, then

that of the gold will be only $\frac{1}{5000}$; and of such wire, 550

feet would be requisite to weigh one grain. In order to remove the coating of silver that surrounds it, the wire must be steeped for a few minutes in warm nitrous acid, which dissolves the silver without any injury to the gold. Dr. W., in his endeavours to make slender gold-wires by the method above-described, found it difficult to drill the central hole in a metal so fine as silver, and therefore tried whether platina might not be substituted for the gold, as in that case its infusibility would allow its being coated with silver, without the necessity of drilling. Having formed a cylindrical mould one-third of an inch in diameter, he fixed in the centre

of it a platina wire previously drawn to the $\frac{1}{100}$ of an inch,

and then filled the mould with silver. When this rod was

drawn to $\frac{1}{30}$, his platina was reduced to $\frac{1}{1000}$, and by suc-

cessive reduction he obtained wires of $\frac{1}{4000}$ and $\frac{1}{5000}$, and

excellent for applying to the eye-pieces of astronomical instruments, and perhaps as fine as can be useful for such purposes. The extremity of a platina wire having been fused into a globule near $\frac{1}{4}$ of an inch in diameter, was next hammered out into a square rod, and then drawn again into a

wire $\frac{1}{253}$ of an inch in diameter. The fusion was effected

by the following simple and easy method suggested by Dr. Marcet:

Marcel:—A piece of wire, about six inches long, having been bent to an angle in the middle, one half of its length was held in the flame of a spirit-lamp impelled by a current of oxygen, and its extremity was thus fused in about half a minute. An inch of the wire above-mentioned duly coated with silver was drawn, till its length was extended to 182 inches; consequently the proportional diminution of the diameter of the platina will be expressed by the square root of 182, so that its measure had become

$$\frac{1}{253 \times 13.5} = \frac{1}{3425}$$

The specific gravity of the coated wire was assumed to be 10.5, and since the weight of 100 inches was 114 grains, its diameter was inferred to be

$$\frac{1}{42.8}$$

of an inch, and just eighty times of the platina thus contained in it. With portions of the platina wire thus obtained, and successively reduced in diameter, its tenacity was ascertained; and the results of several trials shewed in general, that the process of wire-drawing, which is known to improve the strength of metals within moderate limits, continued also to add something to the tenacity of platina,

even as far as $\frac{1}{18,000}$ of an inch, which supported $1\frac{1}{2}$ grain

before it broke; but the wire in which the experiments were made began then to be impaired by repetition of the operation; so that although he afterwards obtained portions

of it as small as $\frac{1}{30,000}$ of an inch in diameter, it was in

many places interrupted, and he could not rely on any trials of its tenacity. For other particulars with regard to these fine wires, we refer to the Phil. Trans. vol. ciii. pt. 1.

WIRE, Silver, is the same with gold wire, except that the latter is gilt, or covered with gold, and the other is not. There are also counterfeit gold and silver wires: the first made of a cylinder of copper, silvered over, then covered with gold; and the second of a like cylinder of copper silvered over, and drawn through the iron, after the same manner as gold and silver wire.

By 43 Geo. III. c. 68. several duties are imposed on wire imported, as set forth in tables annexed to the act; and by c. 69. sched. A. duties are laid upon wire made in Great Britain; and by 49 Geo. III. c. 98. new duties are imposed. Every wire-drawer who shall draw any gilt or silver wire, commonly called 'big wire,' shall take out a licence, for which he shall pay 2*l.*, to be renewed annually on pain of 20*l.* 24 Geo. III. c. 41. One licence suffices for a partnership. Notice is to be given of working on pain of 20*l.*, and the place of working is to be approved by the commissioners under the same penalty. Wire, and bars for making it, and utensils, found in any private workhouse, of which no notice hath been given, shall be forfeited. Officers shall be permitted to enter and survey, and the penalty of obstructing him is 20*l.* 10 Ann. c. 26. Preventing him from taking a just account incurs a forfeiture of 100*l.* 26 Geo. III. c. 77. Just scales and weights shall be kept on pain of 10*l.* Persons using false scales and weights forfeit 100*l.* 10 Geo. III. c. 44. And the same shall be forfeited and seized. 28-Geo. III. c. 37. Ingots or bars of silver, designed for gilt wire, shall be weighed in the presence of the excise officer, before they be covered with gold, and again weighed and marked after the gold is laid on, under penalty of 20*l.* 15 Geo. II. c. 20.

By 10 Ann. c. 26. an allowance of one-fifth is made

for waste in reducing the big wire to small wire. Removing wire before it is surveyed incurs a penalty of 40*l.*; and unsurveyed wire is to be kept separate, on pain of 10*l.*; and the punishment of concealing wire, &c. is a forfeiture of 20*l.* The wire made shall be entered every month, on oath, on pain of 100*l.* The duty must be cleared off in six weeks after entry, on pain of double duty.

By 15 Geo. II. c. 20. and 22 Geo. II. c. 36. no foreign embroidery, or gold or silver brocade, thread, lace, fringe, or work made thereof, or of copper, brass, or other inferior metal, or gold or silver wire, or plate, shall be imported. And by 10 Ann. c. 26. if any person shall export any gold or silver thread, or lace or fringe made of plate wire spun upon silk, he shall have a drawback after the rate of 5*s.* a pound avoirdupois, of such wire thread, lace, or fringe, and of 6*s.* 8*d.* a pound of such gold thread, lace, or fringe.

For regulations concerning the true making of gilt and silver wire, see the statute 15 Geo. II. c. 20. and for prohibiting the felling or working up of foreign gold or silver lace or thread, see 22 Geo. II. c. 36.

WIRE, Brass, is drawn after the same manner as the former. Of this there are divers sizes, suited to the divers kinds of works. The finest is used for the strings of musical instruments, as spinets, harpsichords, manichords, &c.

The pin-makers likewise use vast quantities of wire of several sizes, to make their pins of. See PIN.

WIRE, Iron. See WIRE *supra*.

WIRE-Gauze Safety-Lamp, and **Safety-Lamp**, in the Arts, are lamps constructed to prevent the explosion of inflammable air in mines, by intercepting the communication of the flame on the inside of the lamp with the surrounding atmosphere. The discovery of safety-lamps for this purpose belongs exclusively to our own country, and will form a new era in mining operations. We shall, therefore, state the history of their invention with as much accuracy as possible, amidst the contending claims of the different inventors for priority. The explosions of inflammable air in coal-mines arise from the ignition of carburetted hydrogen evolved from the strata, and mixed with the atmospheric air that circulates through the mine. These explosions very frequently occasion the most fatal effects, destroying the lives of all the persons employed as well as of the horses, and producing great mischief to the subterranean works. Some mines are much more liable to accidents from this cause than others. In some the carburetted hydrogen accumulates slowly from the want of due circulation; in other mines, it is generated very rapidly, issuing from fissures called blowers, which occur either in the roof, the floor, or the sides of the mine.

In the coal-fields of the Tyne and the Wear, it has been estimated that six hundred men and boys were destroyed in two years by explosions in the mines; but these accidents, unless they took place on a large scale, were as much as possible kept from public notice, partly from the fear of alarming the workmen, and partly from the apprehension of blame to the viewers and managers of the works. Of these melancholy catastrophes, few registers are kept in any part of Great Britain; but in the year 1810 an explosion took place in a mine in the parish of Felling near Newcastle, which, from the magnitude of the evil it occasioned, excited a general sensation of horror throughout the country. In this mine, the property of wealthy and liberal owners, no expence had been spared in the introduction of machinery and the most approved methods of ventilation. (See VENTILATION of Mines.) Notwithstanding this, on the 25th of

May 1812, the inflammable air exploded in two discharges from one of the pits, which was shortly followed by a third from another pit.

The depth of these explosions under the surface out-tuned the sound of the reports; but for half a mile round the vibrations of the earth announced the occurrence of the accident before the noise escaped, and an alarm was created four or five miles round by low and hollow rumblings in the air. Immense volumes of dense vapour and coal-dust, with pieces of wood and coal, were driven high into the atmosphere; and the mangled bodies of several men and boys were absolutely thrown out of the shaft. The country in the immediate vicinity was enveloped in darkness, and every kind of machinery near the mouths of the pits was blown to pieces, or set fire to. Out of a hundred and twenty men and boys employed in the mine only thirty-two were saved, three of whom afterwards died. The coal being set fire to, and the subterranean works blown down or destroyed, the owners were compelled to close the mouths of the pits in order to extinguish the fire; and it was not till the seventh or eighth of the following month that it could be re-opened to extract the bodies, which were, many of them, too much mangled, and in too putrescent a state, to be identified by the relatives. A series of similar disasters, in each of which from twenty to thirty-five human beings were destroyed, occurred soon afterwards in the same districts, and even in the Felling mine another explosion took place in December 1813, by which twenty-three men and boys and twelve horses were killed. The only method that had been adopted to prevent explosions, besides the usual modes of ventilation for clearing the mine, was the substitution of steel-mills for candles.

The steel-mill is an instrument for producing light by the collision of flint and steel: it consists of a brass wheel about five inches in diameter, with fifty-two teeth, which works a pinion with eleven teeth. On the axis of the pinion is fitted a thin jagged steel wheel, from five to six inches in diameter; against the circumference of this wheel the sharp edge of a flint is fixed, and the toothed wheel has a handle, which is turned by a boy; the whole machine being fixed in an iron frame suspended by a leather belt. The steel wheel revolves with great velocity, and elicits a stream of scintillations, which give a considerable light. Where the mines were suspected to contain inflammable air, these machines were used; but besides affording only an unsteady light, and being difficult to manage, many instances had occurred of the air igniting from the scintillations of steel-mills. For the purpose of exploring the unworked and more dangerous parts of the mine, the steel-mill was both an inconvenient and incomplete instrument; but until the year 1809 no method of lighting had been attempted which might supersede its use.

About that time Dr. Reid Clanny, a scientific and ingenious physician at Sunderland, commenced a series of experiments, with a view to insulate the gas which might explode in a lamp, and cut off its communication with the surrounding air in the mine. With this intent, he constructed a lamp in which the combustion of the oil or tallow is supported by the ordinary air of the coal-mine supplied by a pair of bellows, and passing through a stratum or reservoir of water below the light; at the same time, a portion of the air already in the lamp is driven through another reservoir in the upper part above the light, and thus the air supplied may explode within the body of the lamp without communicating the flame to the external air, however highly it may be charged with carburetted hydrogen gas. The moment the air enters the lamp it comes in contact with the flame, and consequently only a small portion of it can be exploded, instead

of the whole contents of the lamp; by this means several obvious advantages are secured. The air passing in a brisk current close by the flame carries the snuff with it, so that the light is always clear and steady. The other parts of the lamp were air-tight, and the whole made very strong, with a glass nearly half an inch thick to prevent it from being broken by any common accident. It is capable of being managed by a boy at a much less expence than the steel-mill. This lamp, which, for strength and for security from explosions and accidents, exceeds any other that has since been invented, excited little attention among the coal-workers where it was first made known. Had not the prejudices against improvements prevented its general introduction, more than one thousand lives might have been preserved, which were destroyed in the mining districts of the Tyne and Wear in a few years after its discovery. In its first form, the lamp, though secure, was not made sufficiently light to be portable without being placed on a barrow; but Dr. Clanny afterwards improved it in this respect, by substituting a small pair of bellows to be worked under the right arm; the lamp, being suspended by a leather belt from the left side of the boy who carried it, might in this way be moved into the narrowest or most dangerous parts of the mine. A description of Dr. Clanny's safety-lamp, with a plate, was first given in the Philosophical Transactions of the Royal Society for 1813, part ii. p. 200. In this lamp, however strong may be the currents of air in the mine, the flame cannot be affected by them, and the most dangerous *blower* may be approached in perfect safety. When an explosion takes place in the lamp it extends no farther, and the flame is instantly extinguished; and wherever there is sufficient atmospheric air to support life, this lamp will afford a safe and abundant light. The construction of the lamp was rendered more simple by passing the air through the oil, by which the necessity of the lower reservoir of water was avoided.

In *Plate I. fig. 2. Geology*, is given an outline of the lamp on its original principle, which, though less portable, is, we consider, the safest that has yet been employed. A is the body of the lamp, constructed of copper or block-tin; B, the upper part of the lamp, ending in a conical bent tube, by which the air is discharged after supporting combustion through the water-cistern C and D, the part D being filled with water to keep the lamp cool, if necessary; E, the window of the lamp, made of very thick glass; F, the candle, supported on a tin stand; G, a cistern containing water, through which the air is forced by the bellows; H, a tube from the bellows, which conveys air to the lamp. A flexible leather tube may be fixed to the valve of the bellows, to send atmospheric air from a distance, if necessary. If the lamp be in order, it is scarcely possible to conceive any insulation of the flame more perfect than it presents; and to Dr. Clanny must be allowed the undoubted claim of priority in having first directed the attention of miners to a method of avoiding danger before unknown, and of shewing practically how it might be effected. In the improvement which Dr. Clanny made in this lamp afterwards, to render it more portable, (see *fig. 3.* in the same plate,) *a* is the tube fixed to the lamp, and which conveys the air; *b*, the oil-cistern; *c*, the air aperture, under the burner of the oil; *d*, the flexible tube connected with the bellows; *e, f*, the glass. In both these lamps, the air being supplied by bellows, required the constant attention of a boy; this, however, was the case with the steel-mills, which were in general use before. A lamp that would supply itself with atmospheric air was still a desideratum; when Dr. Clanny discovered, in November 1815, as he was making experiments with the original safety-lamp in an atmosphere of fire-damp in

WIRE-GAUZE SAFETY-LAMP.

in the Horrington mine, near Sunderland; that if the insulation of the lamp were made with hot water, the fire-damp burned silently at the wick, and did not explode within the lamp, as formerly. This he ascertained to be owing to the steam; and he farther discovered, that one part in volume of steam to two of the most explosive mixtures destroyed their inflammability. A similar effect of steam had been before noticed by Von Grothuss, in the 82d volume of the *Annales de Chimie*, but had not been applied to any useful purpose. In December of the same year, Dr. Clanny constructed a steam safety-lamp, which he exhibited to the Society, for preventing accidents in coal-mines, and received their unanimous thanks; and in 1817 he received a gold medal from the Society of Arts for the discovery.

In the steam safety-lamp there is a reservoir of water at the top of the lamp, which is a closed tin box, or cistern. The water is kept boiling by the flame of the lamp, and the steam mixing with the carburetted hydrogen prevents all risk from explosion. The air is supplied through a tube to the upper part of the cistern above the water, and descends, mixed with the steam, down two other tubes, into the body of the lamp. By this means, the fire-damp burns silently and steadily at the wick of the lamp alone for any length of time. Should the carburetted hydrogen exceed the proportion of atmospheric air for supporting combustion, the light is extinguished, but this can rarely happen. It has also the valuable property of keeping cool throughout every part, and under all circumstances; this is effected by the evolution and motion of the steam. This lamp, says Dr. Clanny, is now well known to burn most brilliantly in an atmosphere of fire-damp, even after the original safety-lamp has had the fire-damp exploded within it. The steam-lamp has now been extensively used in several of the northern collieries. Its great recommendation over other inventions is the superior light which it affords. These lamps are made of the strongest tinned iron, with a flat glass in front, three-eighths of an inch in thickness. They are exceedingly strong and durable, and cost about twelve shillings, but might be manufactured on a large scale for half the price.

Fig. 4. represents the short tube by which the air enters into the tube *b*, and this tube supports the water-cistern *c* at the top, being fitted into the tube *a* at the bottom, so as to be taken out and replaced when the water is to be poured in or removed from the cistern *c*. The air which ascends the tube *b* mixes with the steam of the water-cistern, and passes down the two tubes *d*, *d*, to support the combustion of the flame, and afterwards ascends by the side of the cistern through the chimney of the lamp. These tubes are closed at the bottom, and perforated on the sides, to retard the progress of the air, and mix it with the steam before it reaches the flame *e*. The bottom is air-tight; *f* the glass, and *g* the oil-lamp. These lamps are twelve inches in length, exclusively of the chimney. They should be cleared of water, and well dried, after they have been in use, that they may be more durable. When the lamp is first lighted it is necessary to establish a current, which is best done by turning the lamp, so that the tube *a* may be exposed to the current of air; this will be effected in five minutes, and the lamp will afterwards continue to burn regularly and steadily.

Dr. Clanny farther applied the same principle to the construction of a larger lamp, in which were three wicks to burn the inflammable air as it was made to issue through the oil; this is intended to consume the hydro-carburetted gas as it rushes from a blower.

In the history of useful inventions, perhaps no instance of supineness can be adduced, among those interested in any dis-

covery, which equals the inattention shewn for several years by the coal-workers in the north to the valuable labours of Dr. Clanny. We had an opportunity of examining his lamp in 1813, and were satisfied with the complete security which it affords. At that time, however, so far from receiving the patronage he highly merited, he was regarded by many with a strange jealousy, as an officious intruder into the mysteries of mining; mysteries which he had no right to investigate. To Dr. Clanny, however, the first discovery of a safety-lamp is undoubtedly due; and we have no hesitation in asserting our belief that his original safety-lamp is the most secure of any that have since been invented, where dangerous parts of the mine are to be explored, on account of its more complete insulation, and its greater strength. His lamp had also the merit of first suggesting the possibility of insulating the flame in the different lamps which have since been constructed.

The attention of the public was at length directed to the dangerous situation of the men working in the mines by a few gentlemen, who formed a society, in 1813, at Sunderland, entitled *A Society to prevent Accidents in Coal-Mines*. Dr. Gray, rector of Bishop-Wearmouth, an active member of this society, invited sir H. Davy, in 1815, who was then on a visit in the north of England, to examine the collieries with a view to assist the efforts of the society to prevent the accidents to which they were subject. From the information communicated to him by persons employed in the mines, he was induced to commence a series of experiments on carburetted hydrogen gas, which led to several unexpected results, not less interesting to science than useful in their application to the arts. Before proceeding to describe these, we must notice the labours of Mr. Stephenson, an engineer in the Killingworth main colliery, who previously to this time had, as he asserts in a pamphlet on the subject, entitled "*A Description of the Safety-Lamp invented by George Stephenson*," made the discovery that inflammable air will not explode through small apertures. In the same pamphlet he states, that a lamp constructed by him on this principle was tried in the above colliery on the 21st of October 1815, the lamp being carried in safety into a part of the mine where a strong blower of inflammable air was issuing. The experiment, he adds, was immediately repeated in the presence of two persons employed in the works.

These lamps, judging from Mr. Stephenson's own description, yielded but a feeble light. They were afterwards improved; but these improvements bear so close a resemblance to parts of sir H. Davy's lamp, hereafter to be described, that we conceive Mr. Stephenson must labour under no small difficulty in establishing his claim for their original invention. The question, at present agitated with much warmth, can only be decided by a reference to well-established dates and authentic evidence; an investigation not suited to the nature of the present work.

We have little doubt that the insulation obtained in Dr. Clanny's lamp by water first suggested to Mr. Stephenson the possibility that small apertures might intercept the extension of the flame as effectually as water. On this suggestion his first lamp appears constructed, the tube which admitted the air being covered with a slide, to diminish the aperture at pleasure; but the quantity of air which could be safely admitted through one aperture being inadequate to the support of the flame, it was obvious that the only way to ensure both light and safety was to increase the number of apertures, diminishing the size of each. In this manner, it appears that Mr. Stephenson proceeded mechanically, without a correct knowledge of the properties of the gas, or the principles on which the effects were produced. We think, however, that

WIRE-GAUZE SAFETY-LAMP.

that as an approximation to a valuable discovery, Mr. Stephenson's lamp entitled him to the patronage and support which he has received. It ought also to be recollected that Dr. Clanny and Mr. Stephenson both laboured under the disadvantage of living at a distance from the residence of ingenious practical mechanics to execute their inventions in the most simple, cheap, and portable manner; an advantage only to be obtained in the neighbourhood of the metropolis, or of large mechanical manufactories.

Sir H. Davy, after ascertaining that the fire-damp, or inflammable air in coal-mines, is the light carburetted hydrogen gas, as stated by other chemists, proceeded to examine accurately its combustibility and explosive nature. When one part of fire-damp was mixed with one of common air, the mixture burned on the approach of a taper, but did not explode. Two of air and three of fire-damp produced similar results. When four of air and one of fire-damp were exposed to a lighted candle, the mixture being in the quantity of six or seven cubic inches in a narrow-necked bottle, the flame descended to the bottom, but there was no noise. One part of gas inflamed with six parts of air in a similar bottle, producing a slight whistling sound. One part of gas with three of air rather a louder sound. One part with ten, eleven, twelve, thirteen, and fourteen parts, still inflamed, but the violence of the combustion diminished. In one part of gas and fifteen parts of air, the candle burned without explosion, with a greatly-enlarged flame. The same effect was observed, but in a gradually diminishing ratio, as far as thirty parts of the gas to one of common air. The mixture which seemed to possess the greatest explosive power was seven or eight parts of air to one of gas; but the report produced by fifty cubic inches of this mixture was less than that produced by one-tenth of a mixture consisting of two parts of common air and one of pure hydrogen.

It was also very important to ascertain the degree of heat required to explode the different mixtures of fire-damp. A common electrical spark, he found, would not explode five parts of air and one of fire-damp, though it exploded six parts of air and one of the latter gas. Very strong sparks from the discharge of the Leyden jar seemed to have the same power of exploding different mixtures of the gas, as the flame of a taper. Well-burned charcoal, ignited to the strongest heat, did not explode any mixtures of the gas; and when a fire of the same charcoal, which burned without flame, was blown to whiteness by an explosive mixture without producing inflammation. An iron rod at a red or even at a white heat did not inflame explosive mixtures of the gas; but when in brilliant combustion it produced that effect.

The flame of gaseous oxyd of carbon, as well as of olefiant gas, exploded the mixtures of the fire-damp.

In respect of combustibility, says Sir H. Davy, the fire-damp differs materially from the other common inflammable gases. Olefiant gas, when rendered explosive by a mixture of common air, is fired both by charcoal and iron, heated to a dull redness. Gaseous oxyd of carbon, which explodes with two parts of air, is likewise inflammable by hot iron or charcoal. And hydrogen, which explodes when mixed with three-sevenths of air, takes fire at the lowest visible heat of iron or charcoal; and the case is the same with sulphuretted hydrogen.

The importance of these experiments is too obvious to require illustration. Having ascertained the above facts, Sir H. Davy proceeded to examine the degree of expansion of mixtures of fire-damp and air during their explosion, and likewise their power of communicating flame through aper-

tures to other explosive mixtures. It is to this latter part of Sir H. Davy's experiments and its application to safety-lamps, that the controversy respecting the priority of the discovery refers.

When six parts of air and one of fire-damp were exploded over water by a strong electrical spark, the explosion was not very strong; and at the moment of the greatest expansion, the volume of the gas did not appear to be increased more than one-half. In exploding a mixture of one part gas from the distillation of coal, and eight parts of air in a tube one-quarter of an inch in diameter, and one foot long, more than a second was required before the flame reached from one end of the tube to the other, and he could not make any mixture explode in a glass tube one-seventh of an inch in diameter; and this gas was more inflammable than fire-damp, as it consisted of carburetted hydrogen mixed with some olefiant gas.

In exploding mixtures of fire-damp and air in a jar, connected with the atmosphere by an aperture of half an inch, and connected with a bladder by a stop-cock having an aperture of about one-sixth of an inch, the flame passed into the atmosphere, but did not communicate through the stop-cock so as to inflame the mixture in the bladder; and in comparing the power of tubes of metal and those of glass, it appeared that the flame passed more readily through tubes of glass of the same diameter, and that explosions were stopped by metallic tubes of one-fifth of an inch, when they were one inch and a half long; and this phenomenon probably depends upon the heat lost during the explosion, in contact with so great a cooling surface, which brings the temperature of the first portions exploded below that required for firing the other portions.

Metal is a better conductor of heat than glass; and it has been already shewn, that the fire-damp requires a very strong heat for its inflammation.

A mixture of the gas with air, he also found, would not explode in metallic canals or troughs when their diameter was less than one-seventh of an inch, and their depth considerable in proportion to their diameter, nor could explosions be made to pass through such canals.

Azote and carbonic acid, even in small proportions, diminished the velocity of inflammation in explosive mixtures of fire-damp. Azote, when mixed in the proportion of one to six of an explosive mixture containing twelve of air and one of fire-damp, deprived it of its power of explosion; when one part of azote was mixed with seven of an explosive mixture only, a feeble blue flame passed through it.

One part of carbonic acid to seven of an explosive mixture deprived it of the power of exploding; so that its effects are more remarkable than those of azote, probably in consequence of its greater capacity for heat, and probably likewise of its higher conducting power connected with its greater density.

The consideration of these various facts, Sir H. Davy informs us, led him to adopt a form of lamp in which the flame, being supplied with only a limited quantity of air, should produce such a quantity of azote and carbonic acid as to prevent the explosion of the fire-damp; and which, by the nature of its apertures for giving admittance and exit to the air, should be rendered incapable of communicating any explosion to the external air.

If in a close lantern supplied with a small aperture below and another above, a lighted lamp having a very small wick be placed, the natural flame gradually diminishes, till it arrives at a point at which the supply of air is sufficient for the combustion of a certain small quantity of oil; if a lighted taper be introduced into the lantern through a small door

WIRE-GAUZE SAFETY-LAMP.

door in the side, which is instantly closed, both lights will burn for a few seconds, and be extinguished together.

A similar phenomenon occurs: if in a close lantern supplied with a quantity of air merely sufficient to support a certain flame, a mixture of fire-damp and air is gradually admitted, the first effect of the fire-damp is to produce a large flame round that of the lamp, and this flame consuming the oxygen which ought to be supplied to the lamp, and the standard of the power of the air to support flame being lowered by the admixture of fire-damp and by its rarefaction, both the flame of the fire-damp and that of the lamp is extinguished together; and as the air contained a certain quantity of azote and carbonic acid before the admission of the fire-damp, their effect by mixing it is such as to prevent an explosion in any part of the lantern.

In an experiment which sir H. Davy made, to ascertain that the flame was extinguished in the lantern, though the mixture was still explosive which supplied the flame, the lantern was placed on a stand under a large glass receiver standing in water, which was of sufficient capacity to enable the candle to burn for some minutes. A quantity of fire-damp was thrown in from a bladder, so as to render the atmosphere explosive. As the fire-damp mixed with the air, the flame of the taper gradually enlarged till it half filled the lantern; it then gradually diminished, and was suddenly extinguished without the slightest explosion. The air in the receiver was found after the experiment to be highly explosive.

Sir H. Davy then introduced into a glass jar, containing an explosive mixture of one part fire-damp and ten parts of air, a lighted lantern, to which air was supplied by two glass tubes one-tenth of an inch in diameter, and half an inch long. The taper burned at first with a feeble light, the flame soon became enlarged, and was then extinguished. These experiments were several times repeated with a constancy of result. It is evident, he says, from hence, that it is only necessary to use air-tight lanterns supplied with air from tubes or canals of small diameter, or from apertures covered with wire-gauze, placed below the flame, through which explosions cannot be communicated, and having a chimney at the upper part on a similar system for carrying off the foul air.

This principle sir H. Davy adapted to a variety of glass lanterns, in which the air was admitted through small apertures or wire-gauze, with a top protected by the same. These lanterns, however they might have answered for experiments in the laboratory, were not, however, well fitted for practical use; for besides the fragility of common glass, which exposed the miner to explosions from the enlargement of the flame, the glass was liable to become heated and to break, however strong it might be made. This inconvenience was, however, removed by the substitution of a cylinder of fine wire-gauze, forming a close lamp or lantern, into which the air is admitted, and from which it passes through very small apertures. In the first experiments, the wire was of brass the $\frac{1}{16}$ th part of an inch in thickness, and the apertures were not more than the $\frac{1}{16}$ th part of an inch; this was found to stop explosions as well as the long tubes or canals, and to admit a free current of air. The wire-gauze lamp, in its present improved form, is the most simple and portable that has yet been introduced. *Plate V. fig. 5. Geology*, represents the lamp as at present used; *a* represents the single cylinder of wire-gauze; the foldings *aaa* must be very well doubled and fastened by wire. If the cylinder be of twilled gauze, the wire should be at least of the one-fortieth of an inch of iron or copper, and thirty in the warp, and sixteen or eighteen in the weft. If of plain wire-gauze, the

wire should not be less than one-sixtieth of an inch in thickness, and from twenty-eight to thirty both warp and weft; *b* represents the second top, which fits upon *a*; *c* represents a cylinder of brass, in which the wire-gauze is fastened by a screw, to prevent its being separated from the lamp by any blow; *c* is fitted into a female-screw, which receives the main-screw *b* of the lamp *f*, furnished with its safe-trimmer *h*, and safe-feeder for oil *i*.

Lamps on the same principle were constructed, in which the cylinder is made of copper of one-fortieth of an inch in thickness, perforated with longitudinal apertures of not more than one-sixteenth of an inch in length, and the one-thirtieth in breadth. (*See Plate I. fig. 6. Geology.*) In proportion as the copper is thicker, the apertures may be increased in size. This form of the lamp may be proper where such an instrument is only to be occasionally used, but for the general purpose of the collier, sir H. Davy states that wire-gauze is much superior from its flexibility, and the ease with which new cylinders are introduced.

To this lamp a valuable addition has been lately made by the application of a lens before the flame, to condense the rays of light, and direct them to any particular spot. It has the farther advantage of protecting that part of the wire-gauze from coal-dust, by which it is liable to be choked and obscured in a few hours.

In subsequent experiments, sir H. Davy discovered that much thicker wires and larger apertures might be used than were at first applied. This gave to the lamp greater strength, and transmitted more light.

Gauze made of brass wire $\frac{1}{16}$ th of an inch in thickness, and containing only 100 apertures in the square inch, did not communicate explosion in a mixture of one part coal-gas and twelve of common air, so long as the wire was cool; but as soon as the top became hot an explosion took place. A quick lateral motion also enabled it to communicate explosion. With 196 apertures to the square inch, the explosion was not communicated till the wire became strongly hot.

Iron wire-gauze, containing 240 apertures to the square inch, was safe in explosive mixtures of coal-gas, till it became strongly red-hot at the top.

Iron wire-gauze, of 576 apertures to the square inch, or the $\frac{1}{16}$ th part of an inch each in diameter, appears, says sir H. Davy, to be safe under all circumstances, in explosive mixtures of coal-gas. With very fine wire-gauze, mixtures of oxygen and hydrogen gases may be burned without explosion until the brass wire begins to melt.

The explanation which sir H. Davy gives of the effect of wire-gauze, and small tubes in arresting the progress of flame, is as follows:—These results are best explained by considering the nature of the flame of combustible bodies, which in all cases must be considered as the combustion of an *explosive mixture* of inflammable gas, or vapour and air; for it cannot be regarded as a mere combustion at the surface of contact of the inflammable matter: and the fact is proved by holding a taper, or a piece of burning phosphorus, within a large flame made by the combustion of alcohol; the flame of the candle, or of the phosphorus, will appear in the centre of the other flame, proving that there is oxygen even in its interior part.

The heat communicated by flame must depend upon its mass: this is shewn by the fact, that the top of a slender cylinder of wire-gauze hardly ever becomes dull-red in the experiment on an explosive mixture; whilst in a larger cylinder made of the same material, the central part of the top soon becomes bright-red. A large quantity of cold air thrown upon a small flame, lowers its heat beyond the explosive

WIRE-GAUZE SAFETY-LAMP.

explosive point; and in extinguishing a flame by blowing upon it, the effect is probably produced principally by this cause, assisted by a dilution of the explosive mixture.

If a piece of wire-gauze sieve is held over a flame of a lamp, or of coal-gas, it prevents the flame from passing it, and the phenomenon is precisely similar to that exhibited by the wire-gauze cylinders: the air passing through is found very hot, for it will convert paper into charcoal; and it is an explosive mixture, for it will inflame if a lighted taper is presented to it; but it is cooled below the explosive point, by passing through wires even red-hot, and by being mixed with a considerable quantity of air comparatively cold. The real temperature of visible flame is, perhaps, as high as any we are acquainted with. Mr. Tennant was in the habit of shewing an experiment which demonstrates the intensity of its heat. He used to fuse a small filament of platinum in the flame of a common candle; and it is proved by many facts, that a stream of air may be made to render a metallic body quite hot, yet not be itself luminous.

A considerable mass of heated metal is required to inflame even coal-gas, or the contact of the same mixture with an extensive heated surface. An iron-wire of $\frac{1}{16}$ th of an inch, and eight inches long, red-hot, when held perpendicularly in a stream of coal-gas, did not inflame it, nor did a short wire of one-sixth of an inch produce the effect held horizontally; but wire of the same size, when six inches of it were red-hot, and when it was held perpendicularly in a bottle containing an explosive mixture, so that heat was successively communicated to portions of the gas, produced its explosion.

A certain degree of mechanical force, which rapidly throws portions of cold explosive mixture upon flame, prevents explosions at the point of contact. Thus, on pressing an explosive mixture of coal-gas from a syringe, or a gum elastic bottle, it burns only at some distance from the aperture from which it is disengaged.

Taking all these circumstances into account, there appears no difficulty in explaining the combustion of explosive mixtures within, and not without the cylinders: for a current is established from below upwards, and the hottest part of the cylinder is where the results of combustion, the water, carbonic acid, or azote, which are not inflammable, pass out. The gas which enters is not sufficiently heated on the outside of the wire to be exploded; and as the gases are no where confined, there can be no mechanical force pressing currents of flame towards the same point.

Two papers by sir H. Davy, connected with this subject, were afterwards published in the Philosophical Transactions for 1817, entitled "Some Researches on Flame." In these papers, a number of new and extremely interesting experiments on the properties of flame are detailed. The practical application of the results to safety-lamps we shall briefly state, as they explain more clearly the principle on which their safety depends, and the circumstances essentially requisite to their proper construction. Sir H. Davy commences the paper by informing us, that the intensity of the light of flames depends principally upon the production and ignition of solid matter in combustion; and that the heat and light in this process are in a great measure independent phenomena: and he afterwards defines flame to be gaseous matter, heated so highly as to be luminous, and that to a degree of temperature beyond the white heat of solid bodies, as is shewn by the experiment; that air not luminous will communicate this degree of heat; for if we hold a fine platina wire one-twentieth of an inch from the exterior of the middle flame of a spirit-lamp, and conceal the flame by

an opaque body, the wire will become of a white heat in a space where there is no visible light.

When an attempt is made to pass flame through a very fine mesh of wire-gauze at the common temperature, the gauze cools each portion of the elastic matter that passes through it, so as to reduce its temperature below that degree at which it is luminous; and the diminution of temperature must be proportional to the smallness of the mesh and the mass of the metal. The power of a metallic or other tissue, to prevent explosion, will depend upon the heat required to produce the combustion, as compared with that acquired by the tissue; and the flame of the most inflammable substances, and of those that produce most heat in combustion, will pass through a metallic tissue that will intercept the flame of less inflammable substances, or those that produce little heat in combustion. Or the tissue being the same, and impermeable to all flames at common temperatures; yet when heated it will become permeable to each different kind of flame at different temperatures: those which produce most heat will most readily pass through it. A tissue of one hundred apertures to the square inch, made of wire of one-sixtieth part of an inch, will, at common temperatures, intercept the flame of a spirit-lamp, but not that of hydrogen; and when strongly heated will no longer arrest the flame of the spirit-lamp.

The ratio of combustibility of the different gases is to a certain extent proportionate to the masses of heated matter required to inflame them. Thus, an iron-wire of one-fortieth of an inch heated cherry-red will not inflame olefiant gas, but will inflame hydrogen gas: and a wire of one-eighth of an inch heated to the same degree will inflame olefiant gas; but a wire of one-five-hundredth part of an inch must be heated to whiteness to inflame hydrogen.

These circumstances will explain why a mesh of much finer wire is required to prevent the explosion from hydrogen and oxygen from passing; and why so coarse a texture of wire is sufficient to prevent the explosion of the fire-damp, the least combustible of the known inflammable gases.

The following experiments afford a satisfactory and simple explanation of the cause of the stoppage of flame by the wire-gauze lamp. Let the smallest possible flame be made by a single thread of cotton immersed in oil, and burning immediately on the surface of the oil; it will be found to be about one-thirtieth of an inch in diameter. Let a fine iron-wire one-hundred-and-eightieth part of an inch be made into a circle of one-tenth of an inch in diameter, and brought over the flame. Though at such a distance it will instantly extinguish the flame if it be cold; but if it be held above the flame, so as to be slightly heated, the flame may be passed through it without being extinguished. The effect depends entirely on the power of the metal to abstract the heat of the flame. This is shewn by bringing a glass capillary ring of the same diameter and size over the flame: this being a much worse conductor of heat will not extinguish it even when cold. If its size, however, be made greater, and its circumference smaller, it will act like the metallic wire, and require to be heated to prevent its extinguishing the flame.

Suppose a flame to be divided by the wire-gauze into smaller flames, each flame must be extinguished in passing its aperture, till that aperture has attained a temperature sufficient to produce the permanent combustion of the explosive mixture. Where rapid currents of explosive mixtures are made to act upon wire-gauze, it is of course much more rapidly heated, and therefore the same mesh which arrests the flames of explosive mixtures at rest will suffer them to pass when in rapid motion; but by increasing the cooling surface,

WIRE-GAUZE SAFETY-LAMP.

surface, by diminishing the size or increasing the depth of the aperture, all flames, however rapid their motion, may be arrested. Precisely the same law applies to explosions acting in close vessels: very minute apertures, when they are only a few in number, will permit explosions to pass which are arrested by much larger apertures, when they fill a whole surface. A small aperture was drilled at the bottom of a wire-gauze lamp, in the cylindrical ring which confines the wire-gauze; this, though less than one-eighteenth part of an inch in diameter, passed the flame, and fired the external atmosphere, in consequence of the whole force of the explosion of the thin stratum of the mixture included within the cylinder driving the flame through the aperture; though, had the whole ring been composed of such apertures, it would have been perfectly safe. Nothing, says sir Humphrey Davy, can demonstrate more decidedly than these simple facts and observations, that the interruption of flame by solid tissues permeable to light and air, depends on no recondite or mysterious cause, but to their cooling powers simply considered as such.

When light, included in a cage of wire-gauze, is introduced into an explosive atmosphere of fire-damp at rest, the maximum of heat is soon obtained, the radiating power of the wire and the cooling effects of the atmosphere, more efficient from the mixture of inflammable air, preventing it from ever arriving at a temperature equal to that of dull redness. In rapid currents of explosive mixtures of fire-damp, which heat common gauze to a high temperature, twilled gauze, in which the radiating surface is considerably greater and the circulation of air less, preserves an equal temperature. Indeed the heat communicated to the wire by combustion of the fire-damp in wire-gauze lamps is completely in the power of the manufacturer, for by diminishing the apertures, and increasing the mass of metal, or the radiating surface, it may be diminished to any extent. One important circumstance, however, is not here adverted to by sir Humphrey Davy; by increasing the thickness of the wire and diminishing the aperture, the quantity of light transmitted is greatly reduced, and its power of illumination rendered nearly inefficient. Hence the power of the manufacturer to construct a lamp perfectly safe and sufficiently luminous must be limited by certain conditions. However, sir Humphrey Davy informs us, he has lately had lamps made of thick twilled gauze formed of wires the one-fortieth of an inch, sixteen to the warp and thirty to the weft, which being rivetted to a screw cannot be displaced, from its flexibility it cannot be broken, and from its strength cannot be crushed, except by a very strong blow.

From some very ingenious experiments on the combustion of inflammable substances at low temperatures, sir Humphrey Davy discovered that a coil of platina wire, one-seventieth of an inch thick, remains at a white heat when the quantity of coal-gas is increased so as to extinguish the flame of the lamp; hence he has suggested the advantage of introducing a coil of such wire into the safety-lamp, but we do not learn that it has yet been found of practical use. An account of these experiments is given in the Phil. Trans. for 1817.

The principal objections to the use of wire-gauze safety-lamps in mines, and also to other safety-lamps, may be briefly stated; namely, the accidents to which the lamps may be unavoidably subject, and the accidents which may arise from negligence in the use of them; the injury to the health of the men, from remaining in explosive mixtures of fire-damp longer than they would have done before the introduction of these lamps into mines; and lastly, the temptation they present to neglect the more expensive methods of

ventilating mines, and trusting too much to the security of the lamp. The accidents which may happen to the lamp from one or more of the meshes being broken, when made of such slender wire, and exposed to the corrosive effects of mineral waters in the mine, or the rapid oxydation from moisture alone, must be very frequent, independently of accidents from the falling of pieces of coal on the lamp. The breaking of a single wire being sufficient to enlarge the aperture and occasion an explosion, it is obvious that extreme caution is required in the use of the lamps, and a careful inspection of them should be made every day before they are delivered to the men. This we understand is done in extensive collieries, a person being appointed for the sole purpose of inspecting and trimming the lamps. The accidents which may arise from the negligence of a single man, in extensive mines where more than fifty or one hundred persons are employed, are less easy to guard against; the lives of a great number are constantly depending on the carefulness of each person; and, however perfect the instrument may be, no one can feel perfectly safe when the air in the mine is in an explosive state. Some of the lamps were at first so constructed that they could not be opened except by the key of the inspector; but we believe this precaution is not generally introduced, the great object being to get the lamps made as cheap as possible. We conceive it, however, essential to the security of the miners, that the lamp should be closed by a lock, to prevent the men from uncovering the flame. The lamp itself, by the enlargement of the flame, gives due notice when the air of the mine is in an explosive state, and at such times the proper remedy is to be sought in ventilation; for we conceive it to be neither wise nor humane to suffer the men to remain working in an explosive atmosphere, unless under particular circumstances. Should the invention of safety-lamps induce coal proprietors to allow their workmen to remain for a longer time inhaling the fire-damp, or lead them to neglect the only permanent security, that of efficacious ventilation, we should consider the discovery as injurious to the interests of humanity. It would, however, be extremely unfair to decry the merit of any invention from the possible misuse of it. Were coal-mines first opening in a district where they had never before been worked, we believe that in most cases it would be practicable to secure a constant and safe ventilation through all the works: but in districts like those on the Tyne and the Wear, there are numerous old excavations remaining filled with impure air, of which the present miners have little knowledge, having been worked out in remote periods. Any communications accidentally opened with these old workings may suddenly fill a mine with a mixture of fire-damp, in which case the safety-lamp offers the only means of security with which we are acquainted. For viewing the old workings or *wastes* of the mine, which cannot be approached with a common lamp or candle, the safety-lamp is a most invaluable instrument; and in all cases where the steel-mill was formerly used it affords a far more secure and convenient light. Though we have thought it necessary to state the objections which may be urged against the safety-lamp, we conceive that they apply principally to the misuse of it: and the following statement made by sir Humphrey Davy offers the most satisfactory proof of its utility. "It has now been (Jan. 1817) for ten months in the hands of hundreds of common miners in the most dangerous mines in Great Britain, during which time not a single accident has occurred where it has been employed, whilst in other mines much less dangerous, where it has not been adopted, some lives have been lost, and many persons burned."

The farther experience of another year, on a more extended

tended scale, has fully confirmed the conclusions to be drawn from the above statement, and we may justly consider the safety-lamp as one of the most valuable presents which philosophy has made to the useful arts.

WIRE-Grates, in *Gardening*, are contrivances formed of fine wire-work, and used for keeping various kinds of large insects out of vineries, hot-houses, and such places, as being very mischievous to the fruit in them.

WIRE-Heels, &c. a defect and consequent disease in the feet of the horse or other animal. Some, as Gibson, think that narrow heels are for the most part a natural defect, but that they are often rendered incurable by bad shoeing. Some, in shoeing, hollow the quarters so deep and so thin, it is said, that one may almost pinch them in with one's fingers, and think by that means to widen them out by a strong broad-webbed shoe; but this turns them narrow above and *wires their heels*, and dries up or rots the frog. The best way in all such cases is, it is supposed, not to hollow the foot in shoeing, and to pare nothing out but what is rotten or foul. If the foot be hard or dry, or inclined to be ragged, it may be bathed often with chamber-ley; or two pounds of linseed bruised may be boiled in two quarts of chamber-ley to the consistence of a poultice, then adding to it six ounces of soft-soap, and the foot be softened with it every day, rubbing a little of it upon the sole; or, a composition formed of two ounces of bees'-wax, six ounces of hog's-lard, one ounce of tar, and linseed oil as much as will make it into the consistence of a smooth ointment, may be mixed together, and be used daily in the same manner as the foregoing poultice.

The diseases and affections of the feet of these animals have of late been more accurately understood, and better means of relief and cure recommended.

In the case of narrow or contracted heels, attended with inflammation, and mostly confined to the fore-feet, there is great pain; the animal is constantly moving its legs, and generally inclined to lie down. When first taken out, it is almost incapable of performing any of the paces; the weight being so much thrown on the hinder legs. In trotting, the legs are scarcely lifted above the surface of the ground; the steps are very short, and a walk or canter is gone into instead of any other pace. In the gallop, the weight of the body is thrown on the fore-part of the foot; and in trotting, on the heels; which produce very considerable pain, on account of the action of the foot being confined to the quarter in a backward direction.

The disease is mostly caused by improper shoeing, very great and hard exercise, standing in confined situations on litter, and many other such causes.

In effecting a cure in all the more fresh cases of this sort, where the variation from the natural round form of the hoof is not considerable, it may be accomplished without the animal being entirely made to rest, by removing the shoes, and if possible reducing the heels on a line with the inferior part of the frog. The sole parts may be thinned, and that portion which is between the bars of the foot and the crust be hollowed out. The hoofs should likewise be thinned with a proper tool, especially at the quarters. The shoes should not be put on again for two or three weeks in such cases, and the parts from near the coronet to the fetlock be anointed with a blistering liniment, composed of half an ounce of finely-powdered cantharides and four ounces of Barbadoes tar, well mixed together.

And when necessary, three or four pints of blood may be taken from the plate vein, and a rowel be put in the chest.

Mashes, containing nitre in the quantity of an ounce,

are to be occasionally had recourse to. At the same time, the feet of the animal should be put in a trough of warm water for two or three hours every day, so filled as just to cover the hoof-parts of them; gentle walking or trotting exercise being used on such ground as is soft.

Afterwards the shoes which are made use of should be thinner at the heels than those which were taken off, the heels resting well and firmly on the bars and crust. The patent frog may be used when the animal is at rest, as by continuing its use in a proper manner, the foot will gradually regain its natural form and action. See **FROG**.

In such cases, too, the coronet may now be bathed every day with an embrocation composed of an ounce and a half each of marsh-mallow ointment and Barbadoes tar, with half an ounce of spirit of turpentine, well incorporated together; which will promote and hasten the growth of the hoof-part of the foot.

In case the animal has been lame some length of time, and the contraction of the heels is very considerable, it should be put in moist pasture-grounds, to run for some time, carefully lowering the heels every four or five weeks, or oftener if necessary. As soon as the hoof has been elongated from the coronet to the sole, the cure will be completely effected; which will in most cases be accomplished in the course of about five months; at the end of which time the animal will have regained an entirely new circular foot of the natural shape. The animal should then be shod with thin-heeled shoes, which admit the frog-part of the foot to rest upon the ground.

In cases in which the animals cannot be turned out in this manner, they should be provided with a large shed building, well clayed on the bottom part, and preserved soft and moist by the occasional application of water slightly over it.

But though this sort of management may mostly recover and restore the natural shape of the foot, the proper action of it is not restored with such facility. In a great number of cases, the feet become so much altered in their structure and power on account of the long-continued inflammation, that the means of expansion are wholly destroyed; as is often the case in the cartilages that are situated at the higher and hinder part of the foot, which not unfrequently become bony, and, of course, it becomes impossible to regain the action of the foot. As in these cases, the more the foot is exposed, the greater will be the injury and mischief afforded; the only means of relief that can be made use of, is the covering of the foot with such a shoe as is calculated to prevent concussion, which may be accomplished by the application of a bar-shoe that will rest on every part of the crust, and not upon the frog-part of the foot. This is supposed to be the best form of shoe that can be used for the purpose.

In these cases, when the animals are at rest, the feet should be stopped with an ointment, composed of one ounce and a half each of common turpentine and tar, and two ounces and a half of mallow ointment, well mixed together.

In the cases of cracks or separations of the fibres of the hoofs in a perpendicular manner, which when they extend to the coronet are often very troublesome; the animals most liable to them, are those which have either strong brittle hoofs or narrow heels. Blood animals of the horse kind are more subject to them than others.

In the management and cure of them, the parts around the cracks should be made thin by the rasp, when the firing iron should be drawn over above and below them, to the extent of the fissures, in order to prevent their extension. It should

should likewise be carried over the cracks, by which means a slight quantity of tenacious moisture will exude, and glue up the separated parts; which may be covered over with an ointment composed of four ounces of marsh-mallow ointment, and two ounces of common turpentine, spread upon tow, and kept on the parts by bandages.

The animals should have bar-shoes, which may rest firmly on the frogs, and be made hollow in the parts opposite to the seats of the complaints, in order that no pressure may be given to those parts of the feet; rest being given for some days, and then only moderate exercise allowed, until the cracks have descended towards the lower parts of the feet. The coronets and hoofs may be bathed twice a day, as in the above cases of contracted heels, in order that the growth of horn may be promoted. By the use of these means, the animals mostly soon get better.

WIRES of Asteria, in *Natural History*, a name given by authors to a sort of extraneous fossil belonging to the *asteria*, and being a sort of branches from the body of that column.

WIRE of Lapland. The savage inhabitants of Lapland have a sort of shining slender substance in use among them on several occasions, which is much of the thickness and appearance of our silver wire; and is therefore called, by those who do not examine its structure or substance, *Lapland wire*.

The people of this miserable country find many uses in every thing nature has afforded them, and, among the rest, that species of stag called the rein-deer, which is the most frequent animal among them, is not only serviceable in furnishing them with meat, clothes, houses, and the means of carriage and travelling; but its bones make many of their most necessary utensils; and the sinews, which are all carefully separated in the eating, are, by the women, after soaking in water, and beating, spun into a sort of thread, which is of admirable fineness and strength, when wrought to the smallest filaments; but when larger, is very strong, and fit for the purposes of strength and force. Their wire, as it is called, is made of the finest of these threads, covered with tin. The women do this business, and the way they take is to melt a piece of tin, and placing at the edge of it a horn with a hole through it, they draw these finewy threads, covered with the tin, through the hole, which prevents their coming out too thickly covered. This drawing is performed with their teeth, and there is a small piece of bone placed at the top of the hole, where the wire is made flat, so that we always find it rounded on all sides but one, where it is flat.

This wire they use in embroidering their clothes as we do with gold and silver; and they often sell it to strangers, under the notion of its having certain magical virtues. Scheffer, Hist. Lapland.

WIRE-Worm, in *Agriculture*, a most mischievous worm in different sorts of grain-crops. It has been described by Bierkander, in the Swedish Transactions, as having in the grub-state a yellow colour, with the head brown, and the extremities of the jaws black; the body constituted of twelve joints, shining, and hard-skinned; when it changes its skin it is for some time white; a few hairs are scattered here and there, but mostly upon the head and last joint; under the three first joints are six horny and pointed feet, and at the beginning of the last joint, which is round, there are two black spots, one on each side, which are, probably, apertures through which it breathes.

It is considered by some, notwithstanding the almost general opinion of farmers to the contrary, that the disease

of wheat-crops, which is attributed to this insect or worm, depends upon some other cause, as a fault in ploughing, by which the land is left in too light, open, and porous a state or condition, and which prevents the young plants from being fully and properly nourished, and consequently from forming their roots in a proper manner in the ground. And this notion is in some measure supported by the circumstance of the benefit which is afforded by rolling, treading, and otherwise compressing the land.

It has been proved and shewn by many different trials, that this worm is one which is extremely tenacious of life, and consequently not easily destroyed or got quit of by any means which have yet been made use of for the purpose.

WIRE, in *Geography*, one of the smaller Orkney islands, separated from Rousa by a strait called Wire Sound, about three-quarters of a mile in breadth. N. lat. 58° 58'. W. long. 2° 51'.

WIRE. See *WYRE*.

WIREDY, a town of Sweden, in the province of Smaland; 16 miles N.E. of Jonkioping.

WIRESTA, a town of Sweden, in the province of Smaland; 26 miles S.W. of Wexio.

WIRI, two small islands in the gulf of Finland. N. lat. 59° 50'. E. long. 27°.

WIRING, among *Animals*, the operation of putting a sharp-pointed wire up the nostrils of a sheep, so as to pass up into the brain, and produce a discharge in cases of the sturdy, turn, gid, or vertigo. It seems, however, a dangerous remedy, though it is said to have been successful in curing the disease in many cases.

WIRING Fruit-Trees, in *Gardening*, the operation and practice of passing a fine wire round their branches, in order to bring on the fruiting state.

WIRKOWENES, in *Geography*, a town of Poland, in the palatinate of Kiev; 44 miles W.N.W. of Biala-cerkiew.

WIRKSWORTH, an ancient market-town in the wapentake of the same name, in the county of Derby, England, is situated near the southern extremity of the mining district, in a valley nearly surrounded by hills, at the distance of 14 miles N.N.W. from the county-town, and 140 miles N.W. by N. from London. In the year 835, the manor belonged to the abbey of Repton; after the destruction of that monastery by the Danes, it became vested in the crown, to which it appertained at the time of taking the Domesday-survey. King John granted it to William de Ferrars, earl of Derby. Having been forfeited by the attainder of earl Robert in 1265, it was granted, together with the wapentake, by Edward I. to his brother, Edmund, earl of Lancaster; and has ever since formed part of the earldom or duchy of Lancaster. It is now held under the duchy by Richard Arkwright, esq. A market on Wednesdays, and a fair of three days, were granted for this town to Thomas, earl of Lancaster, in 1305. The market is now held on Tuesday, chiefly for butcher's-meat, butter, eggs, and pedlar's-ware: the corn-market is small. Four annual fairs are now held. The town-hall, a handsome brick structure, was built in 1773, by the direction of Thomas, lord Hyde, the chancellor of the duchy. In this hall are held courts-baron for the manor, courts-leet for the wapentake, and barmote-courts for regulating the mines and mineral concerns. The church, a spacious edifice, apparently of the fourteenth century, consists of a nave and side-aisles, a north and south transept, a chancel, and a square tower, supported by four large pillars. In the church-yard is a grammar-school, founded in 1576, by Anthony

Anthony Gell, esq. who endowed it with lands which now produce 17*ol. per annum*. He also founded an alms-house for six poor men, to which he gave a rent-charge of 2*ol.*; this has been augmented by subsequent benefactions. In the town was formerly a meeting-house for Presbyterians, but it is now occupied by a congregation of Independents. Here are also chapels for Baptists and Wesleyan Methodists. In the population return of the year 1811, the inhabitants of this town are enumerated at 3474, occupying 777 houses. The parish of Wirksworth is extensive, and includes, besides the town, fourteen townships or villages, some of which are very populous.—*Beauties of England and Wales*, vol. iii. Derbyshire. By J. Britton and E. W. Brayley, 1803. *Lynons' Magna Britannia*, vol. v. Derbyshire, 1817.

WIRNAU, a town of the county of Henneberg; 5 miles S.E. of Smalkalden.

WIRRAL, or WIREHALL, a strip of land in the county of Chester, extending from the city of Chester to the sea, between the rivers Dee and Mersey.

WIRREY, or ST. ANDREW, one of the Shaint islands. N. lat. 57° 53'. W. long. 6° 19'.

WIRSRUM, a town of Sweden, in the province of Smaland; 46 miles N.N.W. of Calmar.

WIRSTBERGHOTZEN, a town of Westphalia, in the bishopric of Hildesheim; 8 miles S. of Hildesheim.

WIRSUNG, JOHN GEORGE, in *Biography*, was a native of Bavaria, studied medicine at Padua, and was a disciple of Vesling. In 1642 he published the discovery of the pancreatic duct, with which his name is connected; and in the following year he was assassinated by a Dalmatian, under the influence of a passion excited by having been silenced by him in a public disputation. Haller. Eloy.

WISANGI, in *Geography*, a town of Sweden, in West Bothnia, on the Tornea; 95 miles N.N.W. of Tornea.

WISBADEN, a town of Germany, in the principality of Nassau Saarbruck Ufingen. This town was known to the Romans, and the *Heidenische Maur*, or *Heathen Wall*, which runs through the present town of Wisbaden, appears to be a work of that nation; and a part of the boundaries of this town are derived from the lined trenches thrown up by Drusus, opposite to Mentz, for the covering of the Rhine. In the days of the kings of the Franks, in this town was a royal court. At Wisbaden are some medicinal springs, formerly in great repute; 5 miles N.W. of Mentz. N. lat. 50° 3'. E. long. 8° 9'.

WISBECH, a large market-town in the county of Cambridge, England, gives name to a hundred and a deanery, and is situated in the extreme northern part of the county, about 30 miles N. from Ely, 42 from Cambridge, and 90 from London, in the same direction. Wisbech is a great mart for corn, about 100,000 quarters being annually exported from thence by the river Ouse, and the canals communicating with Cambridge, Lynn, and other towns. Other articles of export are rape-seed and long wool, of which great quantities are sent to the Yorkshire clothiers. Timber, from Northamptonshire, is also embarked for the service of the navy. The principal imports are, coals, deals, and wine. The river is navigable up to Wisbech, at spring-tides, flowing six or eight feet, for vessels of 60 tons, which are constantly employed in the corn trade, to London, Hull, and other ports. Prior to the Norman Conquest, Wisbech belonged to the convent of Ely. In 1071 William of Normandy erected a castle of stone at the town;

but this being dismantled, a new castle of brick was built on the scite, between 1478 and 1483, by Morton, bishop of Ely, and which became the episcopal residence. Being purchased by secretary Thurloe during the interregnum, it was rebuilt after designs by Inigo Jones. Reverting at the Restoration to the see of Ely, it was sold some years ago, and on the ground of the detached buildings some good houses have been erected. The church is a spacious, handsome fabric, although of a singular construction, having two naves and two aisles. The naves are lofty, and separated by light slender pillars, with pointed arches; the aisles, which are the most ancient, are divided from their respective naves by low massy pillars and semicircular arches. The tower of the church is beautiful, and notwithstanding the antiquity attributed to it, is proved by records to have been erected posterior to 1520. Wisbech, with the adjacent country, has frequently suffered by inundations, particularly in 1236, when great numbers of small craft, cattle, and men, were destroyed. In 1437, by a breach in the bank of Wisbech fen, upwards of 4000 acres of land were overflowed. But the greatest devastations of this kind occurred in Nov. 1613, by the spring-tide concurring with a violent N.E. wind; and in March 1614, by the melting of the snow in the country. In 1611 the inhabitants obtained a renewal of their charter, which constituted them a body corporate, by the style of the burgesses of Wisbech; but the right of the election of the ten capital burgesses was limited to the possessors of freeholds of the value of 40*s. per annum*. The executive officer, the town-bailiff, although a person wholly unknown to the charter, has the entire management of the estates and affairs of the corporation. The annual income under the management of these capital burgesses, allotted to public and charitable purposes, amounts to about 800*l.* A principal object of this charge is the maintaining of beacons and buoys, and the clearing of the channel of the river Ouse or Wis, from which the town takes its name; precautions highly necessary, on account of the shifting sands between the town and the sea. Among the improvements made in Wisbech of late years, must be mentioned the stone bridge of one elliptic arch, and the new custom-house. The streets are paved, lighted, and watched, at the expense of the corporation. The trade of Wisbech has much increased of late years, through the improved state of the drainage and navigation of the fens. The neighbouring lands are in high cultivation, and are chiefly appropriated to grazing. The sheep and oxen grow to a great size; and considerable numbers are sent off twice every week to London. The inhabitants are almost wholly employed in commerce, the town possessing no kind of manufacture, although the surrounding country produces vast quantities of wool, hemp, and flax. The canal, opened not many years ago, extending from Wisbech river to the river Nene at Outwell, and thence to the Ouse, affords a communication with Norfolk, Suffolk, and the western counties, and which proves very beneficial to the town. In 1781 a literary society was established in Wisbech, and the education of youth is provided for by a free-school, and by two charity-schools, supported by subscription. The dissenters from the established church are not numerous, but have their respective places of worship. The parish, containing 6308 acres, is in the greatest part a very rich arable and pasture land. In 1676 the inhabitants of Wisbech were computed to be 1705; in 1801 they amounted to 5004; and in 1811 to 6300: the inhabited houses were 1237.—*Beauties of England; Cambridgehire*. By J. Britton and E. W. Brayley, 8vo. 1802. *Magna Britannia*, by the Rev. D. Lyfons and S. Lyfons, 4to. 1808.

WISBERG, a town of Germany, in the principality of Culmbach; 8 miles E. of Culmbach.

WISBY, a town of Sweden, on the west coast of the island of Gothland. This is a very ancient staple, and in former times one of the Hanse towns. When Wineta, a place of great trade in the island of Ufedom, near the coast of Pomerania, was destroyed by an inundation, several of its wealthiest inhabitants removed to Wisby. It was likewise frequented by Swedes, Goths, Danes, Normans, French, English, Saxons, Livonians, Spaniards, Russians, Greeks, and other nations. The maritime laws of Wisby were famous in all parts, and adopted along the coast of the Baltic. (See *INSURANCE*.) The wall of Wisby, and the towers with which it is flanked, were built in the year 1289. This town continued in a flourishing condition till the year 1361, when the Danes almost totally destroyed it. The harbour is safe and commodious, but not very large. N. lat. 57° 38'. E. long. 18° 18'.

WISCASSET, a sea-port town of America, in the province of Maine, in the county of Lincoln, on the Sheep cut, with 2083 inhabitants; 30 miles N.E. of Brunswick.

WISCHAU, or **WISKAU**, a town of Moravia, in the circle of Brunn; 15 miles E. of Brunn. N. lat. 49° 17'. E. long. 16° 54'.

WISCHBACH, or **FISCHBACH**, a town of the duchy of Stiria; 5 miles S. of Muertzenschlag.

WISCHGROD, a town of the duchy of Warsaw, on the Vistula; 27 miles S.E. of Poloczko.

WISCHITEN, a town of Lithuania, in the palatinate of Troki; 70 miles W. of Troki.

WISCHKOWA, a town of Bohemia, in the circle of Saatz; 5 miles N.N.E. of Saatz.

WISCHNOWA, a town of Bohemia, in the circle of Beraun; 3 miles E. of Przbiram.

WISDIM, a town of Bohemia, in the circle of Boleslaw; 14 miles W.N.W. of Jung Buntzel.

WISDOM, **SAPIENCE**, usually denotes a higher and more refined knowledge of things, immediately presented to the mind, as it were by intuition, without the assistance of ratiocination.

In this sense, wisdom may be said to be a faculty of the mind, or at least a modification and habit of it.

Sometimes the word is more immediately used in a moral sense, for what we call *prudence* or *discretion*; which consists in the soundness of the judgment, and a conduct answerable to it.

The school-divines sometimes restrain wisdom to the knowledge of the more sublime and remote objects, as that of God, &c. In which sense, theology is properly said to be wisdom.

The Latin word for wisdom is *sapientia*, which literally expresses the sense of tasting; to which wisdom is supposed to have some conformity. The sight, and other senses, only represent to us the surface of things: taste goes deeper, and penetrates into the substances; so that what, *e. gr.* to the feeling seemed cold, to the taste will be found hot: so wisdom, arising from a deep attention to our ideas, goes farther, and frequently judges otherwise than the common apprehensions of men would reach to.

WISE, **MICHAEL**, in *Biography*, an admirable composer for the church, fostered in the Chapel Royal after the Restoration, under captain Henry Cook, at the same time as Humphrey and Blow, three musicians, who not only far surpassed their master in genius and abilities, but all our church composers of the 17th century, except Purcell. However, they prepared the way for his bold and original

genius to expand; as several new melodies, modulations, and happy licences, which we used to think entirely of his invention, upon an attentive examination of their works, appear to have been first suggested by these three fellow-students. Yet, what they had slightly and timidly touched, Purcell treated with the force and courage of a Michael Angelo, whose abilities rendered the difficult easy, and gave to what, in less powerful hands, would have been distortion, facility, and grace.

Dr. Boyce has printed six verse and full anthems, by Wife, which are admirable; and in Dr. Tudway's collection, Brit. Mus., there are seven more, and a whole service in D minor.

He was author of the celebrated two-part song, "Old Chiron thus preached to his pupil Achilles," which is still too well known to need an encomium here.

Michael Wife was killed in a street-fray at Salisbury, by the watchman, in 1687.

The first movement of his verse-anthem for two voices, "The ways of Zion do mourn," is more beautiful and expressive than any grave and pathetic composition for the church of other countries, of the same kind and period of time, that we have hitherto discovered.

The use which the author has made of chromatic intervals at the word *mourn*, is not only happy and masterly, but *new*, even now, at more than a hundred and twenty years distance from the time when the anthem was produced! The whole composition seems to us admirable; and besides the intelligence and merit of the design, the melody is truly plaintive, and capable of the most touching and elegant expression of the greatest fingers of modern times; the harmony too and modulation are such as correspond with the sense of the words, and enforce their expression.

There is an elegance of phrase in a passage of the second movement of the preceding anthem, at the word *down*, which has been lately revived, and in great favour, with a very minute difference, among the first fingers of Italy. The difference consists only in pointing the first note if a crotchet or quaver, and making the second and third notes semiquavers or demisemiquavers.

Wife was a native of Salisbury, in which cathedral he was appointed organist and master of the choristers, in 1668; and in 1675, a gentleman of the chapel royal. In 1686, he was preferred to the place of almoner and master of the boys at St. Paul's. He is said to have been in great favour with Charles II., and being appointed to attend him in a progress, claimed, as king's organist for the time, the privilege of playing to his majesty on the organ, at whatever church he went.

Wise Men of Greece, *Seven*, in the *History of Philosophy*, an appellation given to several eminent men, on whom was bestowed the praise of civil and moral wisdom. The history of these persons, originally without doubt plain and simple, has been rendered obscure and uncertain by traditionary reports. The incident to which this appellation was at first owing was as follows:

In the third year of the 49th Olympiad, it happened that certain youths of Ionia, purchasing from a fisherman of Miletus a large draught of fish, which he had brought to shore, found in the net a golden tripod of great value. Upon this a dispute arose between the fisherman and the purchasers: the former maintaining that he had only sold them the capture of fish; the latter asserting that they had bought the chance of the draught, whatever it might be. The question was referred to the citizens of Miletus, who were of opinion, that in an affair so extraordinary, the Delphic oracle

oracle should be consulted. The answer of the oracle was 'To the Wisest.' In obedience to this answer, the Milesians unanimously adjudged the tripod to Thales. Thales modestly declined the honour intended him by his fellow-citizens, and sent the tripod to Bias, a wise man of Priene; from him it was passed on through several hands, till it came to Solon, the Athenian legislator, who judging that the character of 'the wisest' could not properly belong to any human being, sent the prize of wisdom to Delphos to be dedicated to Apollo. The story, as above related, has in it something fabulous; and the circumstances that attend it are differently related by different writers. It is more probable, says Brucker, that in some public assembly a tripod was proposed as an honorary prize to the man who should recite, in verse, the most excellent maxims of political and moral wisdom, and that the sages who engaged in this generous contest afterwards agreed to dedicate the prize to Apollo. In confirmation of this conjecture it is alleged, from a passage in Plato's Protagoras, that the wise men of this period met together to frame concise precepts and maxims for the conduct of life, and agreed to send such sentences as were thought most valuable to Delphos, to be inscribed in the temple. Hence Apollo is said by the ancients to have been the author of the precept 'Know thyself.'—'E cælo descendit, Γνωθὶ σεαυτὸν.' The names commonly included under the appellation of the Seven Wise Men of Greece are, Thales, Solon, Chilo, Pittacus, Bias, Cleobulus, and Periander. Brucker's *Philos.* by Enfield, vol. i.

WISECK, in *Geography*, a river of Hesse, which runs into the Lahn, near Giessen.

WISELL, a town of the duchy of Stiria; 4 miles N.E. of Rein.

WISEMAN, RICHARD, in *Biography*, was first known as a surgeon in the civil wars of Charles I., and accompanied prince Charles, when a fugitive, in France, Holland, and Flanders. He served for three years in the Spanish navy, and returned with the prince to Scotland, and was made prisoner in the battle of Worcester. After his liberation, in 1652, he settled in London. When Charles II. was restored, he became eminent in his profession, and was made one of the serjeant-surgeons to the king. In May 1676 he appears, from the preface to his works, to have been a sufferer by ill health for twenty years; but the time of his death is not known. The result of his experience appears in "Several Chirurgical Treatises," fol. 1676, 1686, and in 2 vols. 8vo. 1719. The subjects of these treatises are, tumours, ulcers, diseases of the anus, king's-evil, wounds, gunshot-wounds, fractures and luxations, and lues venerea. The course of his practice comprehended more than 600 cases, of which he gives apparently an honest account, recording his failures as well as his cures, and the detail merits attention. In his relation of the miraculous effects of the royal touch in scrofula, it is not easy to reconcile his honesty with his sagacity, though from his own narration, duly considered, the fallacy is easily detected. His writings have long been regarded as standard authority in the examinations at Surgeon's-Hall. *Gen. Biog.*

WISEMAN, Mr., a worthy English musician, who went early in life to Italy, in order to receive lessons on the violin from Tartini, in Padua, who recommended him, in 1736, to one of his favourite scholars, Pasqualino Bini, at Rome, where, after some time, finding himself likely to thrive as a professor, by the patronage of the English nobility and gentry with which that city always abounds in their travels, settled there for the rest of his life; and though not a performer of the first class, being a good

musician, and a man of probity and good conduct, he was not only respected by his countrymen, but by the natives of that city, which, though no longer the capital of the world, is still the capital of Italy and the fine arts.

Mr. Wiseman had resided so long in Italy, that he had almost forgotten his native tongue. In 1770 he lived in the Palazzo Rafaele, without the gates of Rome, where, during the first winter months, he had a weekly concert till the operas began. It was here that the great Raphael lived and died, where there were still some of his paintings in fresco, and where the late duke of York, the prince of Brunswick, and several other great personages, gave concerts to the first people of Rome.

WISEN, in *Geography*, a river of Baden, which runs into the Rhine, near Bâle.

WISENT, a river of Bavaria, which runs into the Rednitz, near Forcheim, in the bishopric of Bamberg.

WISEPPE, a town of France, in the department of the Meuse; 3 miles S. of Stenay.

WISFTARDA, a town of Sweden, in the province of Smaland; 22 miles N. of Carlscrona.

WISHART'S ISLAND, an island in the Pacific ocean. This is one of the Solomon islands, and by the Spaniards called Artreguada. S. lat. 2° 20'. E. long. 150° 55'.

WISIR, a small island in the East Indian sea, near the west coast of Aroo. S. lat. 15° 21'. E. long. 134° 51'.

WISK, or **WIRSK**, a river of England, in the county of York, which runs into the Swale.

WISKA, a river of Sweden, which runs into the sea, 3 miles S. of Waro, in West Gothland.

WISKI, a town of Bohemia, in the circle of Beraun; 4 miles N. of Przibram.

WISLAUFF, a river of Wurtemberg, which runs into the Rems, N.E. of Schorndorff.

WISLITZA, a town of Poland, in the palatinate of Sandomirz; 48 miles W.S.W. of Sandomirz.

WISLOCH, a town of the duchy of Baden, in the palatinate of the Rhine; 14 miles E. of Spire. N. lat. 49° 18'. E. long. 8° 45'.

WISMAR, a town of the duchy of Mecklenburg, situated in a bay of the Baltic, with a good harbour; large, well fortified, and defended by a citadel. This is one of the best and largest places in the country; as, besides six churches, it has also a particular consistory of its own, with a grammar-school, under the direction of eight masters, and is the seat of a Swedish court of justice, erected in the year 1653, both for the district and Swedish Anterior Pomerania. The court consists of a president, a vice-president, and four assessors. It was formerly a Hanse town, and possessed of the privilege of coining; the first origin is not known with any degree of certainty. In the year 1238, it was enlarged; and in the year 1266, obtained the Lubeck rights. In the year 1261, it was annexed to the duchy of Schwerin; in the year 1627, the Imperialists got possession of it; but in the year 1632 were driven out by the Swedes, to whom it was ceded, at the peace of Westphalia, in 1648; 33 miles E. of Lubeck. N. lat. 53° 55'. E. long. 11° 26'.

WISMATH, a town of Austria; 14 miles S. of Ebenfurth.

WISNA, a town of the duchy of Warsaw; 70 miles N.E. of Warsaw.

WISNUM, a town of Sweden, in the province of Warmeland; 25 miles E.N.E. of Carlstadt.

WISOKIA, a town of Lithuania; 20 miles N.N.W. of Brzesc.

WISP, in *Rural Economy*, a term signifying a small bunch of

of straw which is used in rubbing horses down. Wisp is also a term sometimes applied to a rowel or feton put in animals.

WISPEL, in *Commerce*, a corn measure in Germany. A last of wheat contains 3 wispels; and a last of oats only 2 wispels. See **SCHEFFEL**.

WISSANT, in *Geography*, a town of France, in the department of the fraits of Calais; 12 miles N. of Boulogne.

WISSING, WILLIAM, in *Biography*, was born at Amsterdam in 1656. He received instructions in the art of painting from Dondyns, an historical painter at the Hague, but on leaving that master went to Paris, and in the year 1680, came to England, and assisted Lely in his numerous works. After Lely's death, he became rather a favourite, and promised to become a formidable rival to Kneller. He drew all the royal family, and was particularly favoured by the duke of Monmouth, whose portrait he painted several times. The duke of Somers set also patronized him, and employed him to paint himself and his duchess, and the pictures are now at Petworth.

Wissing was appointed principal painter to James II., and was sent by him into Holland, to paint portraits of William and Mary. He did not long survive his return to England, and died at Burleigh, the seat of the earl of Exeter, in 1687, at the age of 31. His heads were painted with softness and delicacy, in a style quite distinct from that of his master, Lely, or his rival, Kneller; too soft, indeed, for character; and his larger pictures lack composition and harmony, both in line and colour.

WISSOKY-MEYTO, in *Geography*. See **HOHENMAUT**.

WISSOWATIUS, ANDREW, in *Biography*, a Socinian divine, was born of a noble family in Lithuania, in 1608, educated in the New Unitarian college at Racow under Crellius, and for some time pursued his studies at Leyden, strictly adhering to the principles of his tutor. Finding, on his return to Poland, that his brethren suffered persecution from the diet of Warsaw, he exerted himself courageously in their defence, and encountered many personal difficulties and sufferings in the exercise of his ministry in various parts of Poland. He was not silenced by the decree issued against Unitarians in 1658, but leading an unsettled life, he was industrious in seizing every opportunity that occurred for making proselytes. In 1660, he was the only person of his party who was present at the "Colloquium Charitativum," where he firmly maintained his opinions against the jesuit Chichovius and others. He is said to have resisted large bribes, as well as to have encountered severe trials, in maintaining his sentiments. Removing to Hungary, he spent two years in learning the language so as to be able to instruct and fortify his brethren in that kingdom. Last of all he retreated to Holland, where he was employed in superintending an edition of the "Bibliotheca Fratrum Polonorum," in 9 vols. fol., and where he died in 1678. His integrity and constancy are highly applauded by the historians of his sect; his writings were numerous, and one of them, published after his death, was entitled "Religio rationalis, seu de Rationis judicio in controversiis, etiam theologiacis ac religiosis adhibendo, tractatus." Gen. Biog.

WISSOWITZ, in *Geography*, a town of Moravia, in the circle of Hradisch; 20 miles E.N.E. of Hradisch.

WIST, WISTA, a quantity or measure of land among our Saxon ancestors; of different dimensions, in different places. In the Monasticon, it is said to be half a hide, or sixty acres: in an old chronicle of the monastery of Battle, it is said to be forty-eight acres.

WIST, in *Geography*, a town of Sweden, in the province of East Gothland; 6 miles S.S.E. of Linköping.

WISTE, a town of the duchy of Bremen; 10 miles S.W. of Bremen.

WISTE, a river of the duchy of Bremen, which runs into the Wumme, 1 mile E. of Ottersberg.

WISTERNITZ, a town of Moravia, in the circle of Olmutz; 4 miles E. of Olmutz.

WISTERNITZ, *Unter*, a town of Moravia, in the circle of Brunn; 22 miles S. of Brunn.

WISTON, or **WIZTON**, a town in the hundred of Dan-gladdan, county of Pembroke, South Wales, at the distance of 5 miles N.E. by E. from Haverford West. It is a contributory borough with Pembroke and Tenby in sending one member to parliament, and is governed by a mayor. The parish contains about 6000 acres: and in the return of the year 1811, the population was enumerated as 607 persons, occupying 103 houses. An annual fair is held on the 8th of November. In ancient times here was a castle of great extent; but it is now in ruins.—Carlisle's Topographical Dictionary of Wales, 4to. 1811.

WISTRIZ, or **WESSERIZ**, a river of Bohemia, which runs into the Egra, 3 miles E. of Schlackenwerth.

WISTYCZA, a town of Lithuania; 5 miles N. of Brzesc.

WISZOGZOD, a town of the duchy of Warsaw; 52 miles N.W. of Warsaw.

WIT, DE, in *Biography*. There were several painters of this name very respectable in their profession. Peter Candido de Wit, born at Bruges in 1548, went to Italy, and became a friend and co-labourer with G. Vasari. He was afterwards employed by the grand duke of Tuscany at Florence, and painted in oil and fresco. The emperor Maximilian invited him to Munich, and there he terminated his career. Gasper de Wit, his brother, painted small landscapes very highly finished, in which he introduced Italian architectural ruins. Of later date was Emanuel de Wit, born at Alkmaer in 1607, and a painter of still life. He afterwards became a painter of architecture and perspective views of churches, &c. which were touched with great clearness, animation, and spirit. He died in 1692. Another of the name, Jacob de Wit, is the flower of the flock. He was born at Amsterdam in 1695, and having exhibited a desire for the pursuit of art, was placed with Van Spiers, an historical painter, for three years. He afterwards went to Antwerp to contemplate the admirable productions of Rubens and Vandyke, which adorned that city; and there he became the pupil of Jacob van Halen, continuing with him two years.

To him we are indebted for the preservation of the composition made by Rubens for four ceilings, divided into thirty-six compartments, in the church of the Jesuits, which was destroyed by lightning in 1718. They have been since engraved from de Wit's sketches by John Prout.

He was principally employed in adorning ceilings and the walls of apartments; and generally chose allegorical and emblematical subjects, which he composed with considerable ingenuity, and coloured in a clear and pleasing manner. He was employed by the magistrates of Amsterdam, in 1736, to adorn their great council-chamber; and his work has had the honour of being applauded by sir J. Reynolds. His sketches for his larger works are touched with great freedom and neatness, and with good colour. He was living in 1744.

WIT, a faculty of the mind, consisting, according to Mr. Locke, in the assembling and putting together of those ideas with quickness and variety, wherein can be found any resemblance or congruity; by which to make up pleasant pictures, and agreeable visions, in the fancy.

This faculty, the same great author observes, is just the contrary of *judgment*, which consists in the separating carefully from one another, of such ideas wherein can be found

the least difference, thereby to avoid being misled by similitude, and, by affinity, to take one thing for another: and hence he accounts for the reason of that common observation, that men who have much wit and prompt memories, have not always the clearest judgment, or deepest reason.

It is the metaphor and allusion wherein, for the most part, consist the entertainment and pleasantries of wit; which strikes in so lively a manner on the fancy, and is therefore so acceptable to all people, because its beauty appears at first sight, and there is required no labour of thought, to examine what truth or reason there is in it. The mind, without looking any farther, rests satisfied with the agreeableness of the picture, and the gaiety of the imagination; and it is a kind of affront to go about to examine it by the severe rules of truth, or reason. Whence it should seem, that wit consists in something that is not perfectly conformable to them. *Essay on Human Understanding*. b. ii. c. xi. s. 2.

Professor Dugald Stewart (*Elem. of the Philosophy of the Human Mind*, p. 302.) adds to Locke's definition of wit, that it implies a power of calling up at pleasure the ideas which it combines; and he inclines to believe, that the entertainment which it gives to the hearer is founded, in a considerable degree, on his surprise, at the command which the man of wit has acquired over a part of the constitution, which is so little subject to the will. Hence it is, that we are more pleased with a *bon mot* which occurs in conversation than with one in print; and that we never fail to receive disgust from wit, when we suspect it to be premeditated. The pleasure, too, which we receive from wit, is heightened, when the original idea is started by one person, and the related idea by another. Accordingly Dr. Campbell has remarked, that a witty repartee is infinitely more pleasing than a witty attack; and that an allusion will appear excellent when thrown out extempore in conversation, which would be deemed execrable in print.

To the same purpose another ingenious writer has observed upon Mr. Locke's description of wit, that every resemblance of ideas is not that which we call wit, unless it be such an one that gives delight and surprise. These two properties, he says, seem essential to wit, more particularly the latter of them. In order, therefore, that the resemblance in the ideas be wit, it is necessary they should not lie too near one another in the nature of things; for where the likeness is obvious, it gives no surprise. *Spectator*, vol. i. N^o 62.

From this account of the nature of wit, it is easy to perceive what good reason Cicero had for saying (*De Orat. lib. ii. cap. 54.*) *Wit is a thing not to be learned*: it is the offspring of nature, and proper effect of a bright and lively fancy. Cicero reduces wit to two kinds, *viz. cavillatio*, which, in our language, may be called *continued wit*, or humour, and *dicacitas*, which may be termed *concise wit*, or jesting.

The ingenious professor above cited suggests the following difference between invention in the arts and sciences and wit. The former depends, in most instances, on a combination of those ideas which are connected by the less obvious principles of association; and it may be called forth in almost any mind by the pressure of external circumstances. The ideas which must be combined in order to produce the latter are chiefly such as are associated by those slighter connections which take place when the mind is careless and disengaged. "If you have real wit," says lord Chesterfield, "it will flow spontaneously, and you need not aim at it; for in that case, the rule of the gospel is reversed; and it will prove, Seek and you shall not find." Accordingly wit is promoted by a certain degree of intoxication, which prevents the exercise of that attention which is necessary for invention in matters of science.

For the nature of wit in general, the different kinds of it, its use to an orator, and the manner in which it ought to be conducted, see Ward's *Orat.* vol. ii. p. 195, &c.

WIT is also an appellation given to persons possessed of the faculty called *wit, esprit*.

A French author, who, in 1695, published a "Treatise of Wit, du Bel Esprit," lays down four characters of it.

1. A man, who, with an open air and easy motions, affects those he converses with agreeably; and on any subject that presents itself, advances new thoughts, and adorns them with a sprightly turn; is, all the world over, a wit.

2. Another, who, less solicitous about the choice and delicacy of his sentiments, knows how to make himself valued by I know not what elevation of discourse; who draws much attention, and shews great vivacity in his speaking, and readiness in his answers; is likewise acknowledged a wit.

3. A third, who takes less care about thinking than about speaking well: who affects fine words, though perhaps low and poor in matter; who pleases by an easy pronunciation, and a certain tone of voice, is placed in the same rank.

4. Another, whose chief aim is not to make himself esteemed, so much as to raise mirth and laughter; who jokes pertinently, rallies pleasantly, and finds something to amuse himself with in every petty subject; is likewise allowed a wit.

Yet, it may be observed, that in all these cases, there is nothing of real wit, as above defined; but the whole is *imagination*, or *memory* at most: nay the whole is no more than what temperament may give.

A true wit must have a just faculty of discernment; must have, at the same time, both great energy, and peculiar delicacy, in his sentiments; his imagination must be noble, and at the same time happy and agreeable; his expressions polite and well turned; without any thing of parade or vanity in his discourse, or his carriage. It is not at all essential to a wit, to be ever hunting after the brilliant; still studying fine thoughts, and affecting to say nothing but what may strike and surprise.

This is a fault very frequent in dramatic persons: the duke of Buckingham rallies it very justly.

"What is that thing which we sheer wit do call?
'Tis when the wit of some great writer shall
So overflow, that is, be none at all,
That ev'n his fools speak sense —."

From the account we have given in the preceding article of the difference between invention and wit, it appears, that those who have the reputation of wits are commonly more confident in their own powers, who allow the train of their ideas to follow, in a great measure, its natural course, and hazard in company every thing, good or bad, which occurs to them. Men of modesty and taste seldom attempt wit in a promiscuous society; or if they are forced to make such an exertion, they are seldom successful. Such men, however, in the circle of their friends, to whom they can unbosom themselves without reserve, are frequently the most amusing and the most interesting of companions; as the vivacity of their wit is tempered by a correct judgment and refined manners: and as its effect is heightened by that sensibility and delicacy, with which we so rarely find it accompanied in the common intercourse of life. When a man of wit makes an exertion to distinguish himself, his sallies are commonly too far-fetched to please. He brings his mind into a state approaching that of the inventor, and becomes rather ingenious than witty.

Genuine wit, says lord Chesterfield, never made any man laugh since the creation of the world: upon which profess-

for Stewart remarks, that this observation is just, if by genuine wit we mean wit wholly divested of every mixture of humour; and if by laughter we mean that convulsive and noisy agitation which is excited by the ludicrous. But there is unquestionably a smile appropriated to the flashes of wit; — a smile of surprise and wonder: — not altogether unlike the effect produced on the mind and the countenance by a feat of legerdemain when executed with uncommon excess.

Humour, say our critics, is the genuine wit of comedy.

WIT, *Child*. See CHILD-WIT.

WIT-FISH, in *Ichthyology*, a name given by the Dutch in the East Indies to a fish common on those coasts, and seeming to be of the tania kind. It is of the size of our common whiting. Its back is straight and even, and its belly prominent; its snout is pointed somewhat upwards, and tail forked. It has one single spine or prickle on its back, and has a long belly-fin reaching from the head to near the tail; its whole body is friated, and it has two long filaments or beards hanging from its snout, and is a very fine and delicate fish. Ray.

WIT-FISH is also the name given by the Dutch to an East Indian fish, called by Mr. Ray, *Albula Indica*.

WITASARI, in *Geography*, a town of Sweden, in Tavastland; 70 miles N.N.E. of Jamsio.

WITCH of *Endor*, in *Biblical History*, a woman who had a familiar spirit, and who was employed by Saul to consult the deceased Samuel concerning the issue of his contest with the Philistines. See 1 Sam. xxviii.

The explication of this part of sacred history has greatly perplexed commentators and critics. Some, in deference to the authority of the ancient fathers of the Christian church, who ascribed to magicians and necromancers the power of calling up the souls of the dead, have given a literal interpretation of this history, and supposed that Samuel actually appeared to Saul. But to this opinion it has been justly objected, that it is repugnant to the order of the natural world, and to the doctrines of revelation respecting the state of the dead. It cannot be supposed consistent with a just reverence of God to believe, that he has subjected the souls of the departed, not excepting those of the most eminent saints and prophets, to be remanded back from their distinct abodes, by the practice of the most execrable rites, and at the call of some of the vilest mortals, and compelled to reveal what he has seen fit to conceal. Natural reason confirms the suffrage of scripture, when it brands the whole magic art, to which evocations of the dead, and all necromantic divinations appertain, as founded in imposture. Others, who cannot admit that witches are able to disturb the souls of good men, much less of prophets, are nevertheless of opinion, that these wretched women can cause the devil to counterfeit the souls of the dead; and that in the case before us, an evil spirit appeared before Saul in the likeness of Samuel. (See Patrick on 1 Sam. xxviii. 12.) But this opinion gives an unwarrantable advantage for the support of idolatry to those impostures that were practised by heathen forcerers and diviners. Besides, the very apparition of a spiritual and incorporeal being, and the gift of prophecy, are real miracles, and cannot take place but by divine appointment: and lastly, the historian calls the appearance to Saul Samuel, which he could not do with truth, if it was no other than the devil, who here appears, not as a tempter, but as a very severe reprover of impiety and wickedness.

Many learned men have, therefore, maintained, that it was neither Samuel, nor an evil spirit, who here appeared to Saul; but that the whole was the work of human imposture. In support of this opinion it may be pleaded, that

the woman to whom Saul applied to call up Samuel was merely a ventriloquist, possessing an art very serviceable to those who counterfeited the answers of the dead. This opinion, however, like the foregoing one, contradicts the sacred historian, who not only represents the Pythoness as affirming, but himself affirms, that she saw Samuel, and that Samuel spoke to Saul: nor has he dropt the least hint that it was not the real Samuel of whom he was speaking.

Others have supposed, that the appearance of Samuel to Saul was a divine miracle: though whether the miracle consisted in raising Samuel, or in presenting an image or representation of him before Saul, it is not necessary to determine. Accordingly, the apparition must be ascribed, not to the power of enchantment, but to the immediate appointment of God, as a rebuke and punishment to Saul. This opinion is maintained by Dr. Waterland, in his *Sermons*, vol. ii. p. 267, and defended by Dr. Delany in his *Life of David*; but combated by Dr. Chandler, with objections which, as far as they affect the scripture history of the matter, are answered or obviated by Mr. Farmer, in his *Dissertation on Miracles*, p. 486, &c.

WITCH-HAZLE, in *Botany*. See HAZLE.

WITCH ISLAND, in *Geography*, one of the smaller Virgin islands; 6 miles E. of St. John.

WITCHCRAFT, the crime of forcery, especially in women.

Many think there may be some foundation for what we call fascination and witchcraft. We have innumerable instances and histories to this purpose; which it would not be fair to set aside, merely because they are not reconcilable to our philosophy: but, as it happens, there seems to be something in philosophy to countenance some of them.

Indeed, the ridiculous stories that are generally told, and the many impostures and delusions that have been discovered, in all ages, are sufficient to demolish all faith in such a dubious crime; if the contrary evidence were not also extremely strong. Wherefore, (says judge Blackstone,) it seems to be the most eligible way to conclude, with an ingenious writer of our own (*Spect.* N^o 117.), that in general there has been such a thing as witchcraft, though one cannot give credit to any particular modern instance of it. Some readers will, however, probably dissent from this inference of Mr. Addison, and the opinion of the learned judge, and incline to consider witchcraft in general as a species of imposture. See MAGICIAN, and MIRACLE.

What the writers in favour of the opinion advance, as their reasons, is as follows:

All living things, they say, emit effluvia, both by the breath and the pores of the skin. All bodies, therefore, within the sphere of their perspiratory or expiratory effluvia, will be affected by them; and that, in this or another manner, according to the quality of the effluvia; and in this or that degree, according to the disposition of the emittent and recipient parts.

This, indeed, is incontestible; nor need we produce instances of animals exhaling sweet or stinking smells; or of infectious diseases conveyed by effluvia, &c. in confirmation of it.

Now, of all parts of an animal body, the eye, we know, is the quickest. It moves with the greatest celerity, and in all the variety of directions. Again, its coat and humours are permeable as any other part of the body (witness the rays of light it so copiously receives.) The eye, therefore, no doubt, emits its effluvia like the other parts. The fine humours of the eye must be continually exhaling. The heat of the pervading rays will rarefy and attenuate them: and that, with the subtle juice or spirit of the neighbour-

ing optic nerve; supplied in great abundance by the vicinity of the brain, must make a fund of volatile matter to be dispensed, and, as it were, determined by the eye.

Here, then, we have both the dart, and the hand to fling it. The one furnished with all the force and vehemence, and the other with all the sharpness and activity, one would require. No wonder if their effects be great!

Do but conceive the eye as a sling, capable of the swiftest and intensest motions and vibrations: and again, as communicating with a source of such matter, as the nervous juice elaborated in the brain; a matter so subtle and penetrating, that it is supposed to fly instantaneously through the solid capillaments of the nerves; and so active and forcible, that it distends and convulses the muscles, and distorts the limbs, and alters the whole habitude of the body, giving motion and action to a mass of inert, inactive matter. A projectile of such a nature, flung by such an engine as the eye, must have an effect wherever it strikes: and the effect will be limited and modified by the circumstances of the distance, the impetus of the eye, the quality, subtilty, acrimony, &c. of the juices, and the delicacy, coarseness, &c. of the object it falls on.

This theory, it is supposed by many, may account for some of the phenomena of witchcraft, particularly of that branch called fascination. It is certain the eye has always been esteemed the chief seat, or rather organ, of witchcraft; though, by most, without knowing why, or wherefore: the effect was apparently owing to the eye; but how, was not dreamed of. Thus, the phrase, to have an *evil eye*, imports as much as to be a witch. And hence Virgil,

“Nescio quis teneros oculus mihi fascinat agnos.”

Again, old bilious persons are those most frequently supposed to have the faculty; the nervous juice in them being depraved and irritated by a vicious habitude of body, and so rendered more penetrating and malignant. And young persons, chiefly children and girls, are most affected by it; because their pores are patent, their juices incoherent, and their fibres delicate and susceptible. Accordingly the witchcraft mentioned by Virgil only reaches to the tender lambs.

Lastly, the faculty is only exercised when the person is displeased, provoked, irritated, &c. it requiring some extraordinary stress and emotion of mind to dart a proper quantity of the effluvia, with a sufficient impetus, to produce the effect at a distance. That the eye has some very considerable powers is past dispute.

The ancient naturalists assure us, that the basilisk and ophlepa kill other animals merely by staring at them. If this fail of credit, a late author assures us to have seen a mouse running round a large snake, which stood looking earnestly at it, with its mouth open; still the mouse made less and less circles about it; crying all the while, as if compelled to it; and, at last, with much seeming reluctance, ran into the gaping mouth, and was immediately swallowed.

Who has not observed a setting-dog; and the effects of its eye on the partridge? The poor bird, when once its eyes meet those of the dog, stands as if confounded, regardless of itself, and easily lets the net be drawn over it. We remember to have read of squirrels also stupified and overcome by a dog's staring hard at them, and thus made to drop out of the trees into his mouth.

That man is not secure from the like affections is matter of easy observation. Few people but have, again and again, felt the effects of an angry, a fierce, a commanding, a dis-

dainful, a lascivious, an intreating eye, &c. These effects of the eye, at least, make a kind of witchcraft. But our readers will excuse our enlarging.

Witchcraft prevailed to such a degree both in England and Scotland in the 16th century, that it attracted the attention of government under the reign of Henry VIII., in whose 33d year was enacted a statute which adjudged all witchcraft and forcery to be felony without benefit of clergy; and at the commencement of the reign of Elizabeth, the evil seems to have been very much on the increase; for bishop Jewel, in a sermon preached before the queen in 1558, tells her; “It may please your grace to understand that witches and forcerers within these four last years are marvellously increased within your grace's realm. Your grace's subjects pine away even unto the death, their colour fadeth, their flesh rotteth, their speech is benumbed, their senses are bereft; I pray God they never practise further than upon the subject.” Of the prevalence of this delusion in 1584, we have the testimony of Reginald Scot, in his treatise intitled “The Discoverie of Witchcraft,” written in behalf of the poor, the aged, and the simple, as the author informs us; and it reflects singular discredit on the age in which it was produced, that a detection so complete, both with regard to argument and fact, should have failed in effecting its purpose. The mischief, instead of being restrained, was rapidly accelerated by the publication of the “Dæmonologie” of king James, at Edinburgh, in the year 1597; and the contagion was promoted by the succession of James to the throne of Elizabeth. In the year 1603, the royal treatise was printed at London, with an alarming preface concerning the increase of witches or enchanters, “these detestable slaves of the devil;” and it was accompanied by a new statute against witches, which describes the crime in a variety of particulars, and enacts, that offenders, duly and lawfully convicted and attainted, shall suffer death. Reginald Scot, in the treatise above-mentioned, has portrayed at large the character of those who were branded with the appellation of witches, stating the deeds that were imputed to them, and the nature of their supposed compact with the devil. The abode of a witch is admirably described by Spenser, the description being formed from an existing subject:

“There in a gloomy hollow glen she found
A little cottage built of sticks and reedes
In homely wise, and wald with fods around;
In which a witch did dwell, in loathly weedes
And wilful want, all careles of her needes:
So choosing solitarie to abide
Far from all neighbours, that her devilish deedes
And hellish arts from people she might hide,
And hurt far off unknowne whom ever she envie.”
Faerie Queene.

Scot has, with singular industry, collected from every writer on the subject the minutiz of witchcraft, and he has annexed comments for the purpose of refuting and exposing them; whereas James, the royal pedant, wrote in defence of this folly, and, unfortunately for truth and humanity, the doctrine of the monarch was preferred to that of the sage.

The old laws made in England and Scotland against conjuration and witchcraft are repealed by a late statute, and no person is to be prosecuted for any such crime. 9 Geo. II. c. 5. See CONJURATION.

WITCHES-BUTTER, a name given by the common people of England to a sort of tremella growing on the bark of old trees, in form of a corrugated membrane.

WITELSHOFEN, in *Geography*, a town of Germany,

many, in the margravate of Anspach; 7 miles S.E. of Creilshcim.

WITGENAU, or WITCHENAU, a town of Lusatia, on the Elster; 13 miles N.N.W. of Budissen. N. lat. $51^{\circ} 20'$. E. long. $14^{\circ} 16'$.

WITGENAU, or *Wittengau*, or *Trsebon*, a town of Bohemia, in the circle of Bechin, on the river Launicz; 22 miles S.S.E. of Bechin. N. lat. $49^{\circ} 4'$. E. long. $14^{\circ} 40'$.

WITGENSTEIN, a county of Germany, situated between the principalities of Hesse Darmstadt, Nassau Dillenburgh, and the duchy of Westphalia; about 18 miles long, and 12 broad. Some parts are mountainous and woody, and contain mines of silver, copper, and iron; the pastures are good, but the arable land inconsiderable. The principal rivers are the Lahn and the Eder. It is united to the county of Sayn, and that princely house is divided into two branches, Sayn Witgenstein of Witgenstein, and Sayn Witgenstein of Berleburg, each of which had a distinct vote in the Imperial college, and in the diet of the Upper Rhine. The county takes its name from a feat, the residence of the counts, which is situated on a mountain; 1 mile N. of Laafphe.

WITGEWALT, a town of Prussia, in Oberland; 8 miles N.E. of Osterrode.

WITH-VINE, or WINE, in *Agriculture*, a term provincially signifying couch, or couch-grass. See *BIND-Weed*.

WITHAM, in *Geography*, a market-town and parish in the hundred of the same name, in the county of Essex, England, situated on a branch of the river Blackwater, $8\frac{3}{4}$ miles N.E. from Chelmsford, and $37\frac{3}{4}$ in the same direction from London. By the parliamentary returns of 1811, the number of houses in the parish was 466, and the inhabitants amounted to 2352. Witham has a weekly market on Tuesday, and fairs on Friday and Saturday of Whit-week, on the 14th of September, and 8th of November. The petty sessions for the Witham division of the county are also held in the town. Witham is supposed to have been constituted a town by Edward the Elder, though perhaps it was only restored by him, at least the part on Cheping Hill round the church, which stands about half a mile N.W. from the other part of the town. On this eminence are considerable remains of a circular camp, inclosed by a double ditch and rampart. From this work, and the quantity of Roman bricks worked up in the body and tower of the church, Witham has been thought to occupy the position of the Canonium of Antoninus. The manor was anciently possessed by earl Harold, and afterwards by Eustace, earl of Boulogne, who married the sister of Edward the Confessor. Near the east end of the town is a mansion, now possessed by Thomas Kynaston, esq., but formerly belonging to the late earl of Abereorn. Faulkbourne-hall, between one and two miles N.W. from Witham church, is the seat of colonel Bullock, formerly member of parliament for the county of Essex. Here is a cedar-tree, about nineteen feet in circumference near the ground. A coin of Domitian and vestiges of walls indicate the Romans to have had a villa at this place.—*Beauties of England and Wales, Essex*. By J. Britton and E.W. Brayley, 8vo. 1808.

WITHAM, a river of England, in the county of Lincoln, which rises in the south part of Lincolnshire, on the borders of Leicestershire, passes by Grantham to Lincoln, where it becomes navigable; from thence it passes by Tatterfall, Boston, &c. and runs into the German sea, 5 miles below Boston, in what are called the *Wasbes*.

WITHE, in *Agriculture*, a small twisted stick of any kind used as a band.

WITHER-BAND, in *Rural Economy*, the band or piece of iron which is laid underneath a saddle, about four fingers above the withers of the horse, to keep tight the two pieces of wood that form the bow of the saddle.

WITHER-WRUNG, in the *Manege*. A horse is said to be wither-wrung, when he has got a hurt in the withers; which sort of hurts it is very hard to cure. See *WITHERS*.

WITHERING, WILLIAM, M.D. F.R.S., in *Biography*, was born in 1741, and finished his medical education in the university of Edinburgh, where he took his degree of doctor in 1766. From Stafford, where he first settled and married, he removed to Birmingham, and speedily attained by his skill and assiduity to very extensive and profitable practice; without seeking much society or neglecting his scientific pursuits in order to secure it. The chief objects of his attention, independently of his professional engagements, were botany and chemistry. The result of his scientific inquiries and labours appears in the following list of his valuable publications; viz. "A Botanical Arrangement of British Plants," in 2 vols. 8vo. 1776, which passed through two more editions, in 1787, 3 vols., and in 1796, 4 vols., with numerous improvements and additions, some of which were suggested by his friends, and particularly by Dr. Stokes. In chemistry and mineralogy, a translation of Bergman's "Sciagraphia Regni Mineralis," 1783, and the following papers in the *Philosophical Transactions*; "Experiments on different Kinds of Marle found in Staffordshire," 1773; an "Analysis of the Toad-stone of Derbyshire," 1782; "Experiments on the Terra Ponderosa," 1784; and "Analysis of a Hot Mineral Spring in Portugal," 1798. In the improvement of his own profession, "Account of the Scarlet Fever and Sore Throat, particularly as it appeared at Birmingham in the year 1778;" and "An Account of the Fox-glove and some of its Medical Uses; with Practical Remarks on the Dropsy and other Diseases," 1785. Subject to pulmonic attacks, which weakened his lungs, he thought it necessary, in 1793 and 1794, to pass the winter in a warmer climate, and he fixed on Lisbon. Afterwards he became incapable of his former professional exertions, and died at the Larches, near Birmingham, in November 1799, at the age of 58. In his intellectual character he joined unremitting application with sagacity and discernment. In his medical practice he limited prescription to that quantity and kind of medicine which was absolutely necessary for his patients; and if any in the inferior branches of the profession disliked this mode of practice, their disapprobation of it was a testimony in its favour. In his disposition he was mild and humane; and his natural reserve did not preclude him from the pleasure of rational society. His valuable library and handsome property were inherited by an only son. *Gen. Biog.*

WITHERING, in *Medicine*. See *ARIDURA*.

WITHERING of a Cow, is when, after calving, she does not cast her cleanting, which, if not timely remedied, will kill her.

WITHERINGIA, in *Botany*, was so named by the great French botanist, M. L'HERITIER, (see that article,) in compliment to the late Dr. William Withering, F.R.S. F.L.S., the well-known author of a most useful and popular English work, entitled an "Arrangement of British Plants," which has gone through several editions, in some of the earlier of which Dr. Stokes was his coadjutor. (See *STOKESIA*.) —L'Herit. Sert. Angl. 33. Schreb. Gen. 791. Willd. Sp.

Sp. Pl. v. 1. 622. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 248. ed. 1. v. 1. 149. Juss. 450. Lamarck Illustr. t. 82.—Clafs and order, *Tetrandria Monogynia*. Nat. Ord. *Lurida*, Linn. *Solanca*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very short, obfcurely four-toothed, permanent. *Cor.* of one petal, wheel-shaped: tube very short, nearly globular: limb in four deep, lanceolate, acute, recurved fegments. Nectary four fightly-bordered cavities, in the tube of the petal. *Stam.* Filaments four, erect, roundifh, downy, inferted into the bafe of the corolla; anthers converging, ovate, two-lobed, burfting at the fides. *Pift.* Germen fuperior, ovate; ftyle thread-shaped, rather longer than the ftamens; ftigma capitate. *Peric.* Berry roundifh, of two cells. *Seeds* numerous, inferted into the divided receptacle.

Eff. Ch. Corolla deeply four-cleft, reflexed; its tube with four external prominences, internally concave. Calyx obfcurely four-toothed. Anthers converging, burfting laterally. Berry with two cells, and many feeds.

1. *W. folanacea*. Yellow-flowered Witheringia. Willd. n. 1. Ait. n. 1. L'Herit. Sert. Angl. 33. t. 1.—Native of South America. A ftove plant, flowering moft part of the year, and cultivated as early as the year 1742 by the celebrated lord Petre. Its appearance and characters, fo nearly approaching to *Solanum*, had caufed this plant to be neglected by botanifts, till the eager and piercing eyes of M. L'Heritier detected its differences, and eftablifhed its generic characters. The mode of burfting of the *anthers* more efpecially ftamp the genus as diftinct from *Solanum*. The *root* is perennial. *Stem* herbaceous, hardly a foot high, round, downy, reddifh, rendered flightly angular by the decurrent *footftalks*. *Leaves* in alternate pairs, ftalked, ovate-oblong, acute, wavy, entire, rather downy, four or five inches long. *Flowers* about the fize and fhape of *Solanum nigrum*, except being only four-cleft, pale yellow, drooping, in many-flowered, axillary, feffile *umbels*; their *ftalks* round, fmoth, half an inch, or more, in length. *Stamens* whitifh, internally hairy. Few exotics are lefs likely to be cultivated for ornament, however interefting for the fake of its name and characters to a fcientific botanift.

WITHERITE, in *Mineralogy*, a name given to the carbonate of barytes, in honour of Dr. Withering, by whom this mineral was frft difcovered, as containing an earth before unknown. (See BARYTES.) Witherite occurs generally mafive, and fometimes cryftallized, in fix-fided prifms terminated by fix-fided pyramids, in which the edges and points are often truncated. It occurs alfo in double fix-fided pyramids. When mafive, it is often found in globular concretions, which have a radiated diverging ftructure. The principal fracture has a fhining luftre; the crofs fracture is glimmering. It is tranflucent, and is moft generally of a yellowifh-white colour, but is fometimes of a pale blueifh-grey, or flefth-red. Witherite is eafily frangible; it breaks into wedge-shaped fragments; it yields eafily to the knife.

The fpecific gravity is 4.3; it decrepitates flightly before the blow-pipe, and melts very readily into a white enamel. It is foluble with effervescence in dilute muriatic or nitric acid. It contains,

Barytes	-	-	-	-	-	79.66
Carbonic acid	-	-	-	-	-	20.
Water	-	-	-	-	-	.33

Witherite was frft difcovered at Anglefark, in Lancafhire, in a vein of lead-ore, accompanied with heavy fpar.

It occurs in confiderable quantities on the weftern fide of Yorkfhire, and in the counties of Northumberland, Durham, and Weftmoreland, in veins which traverse mountain lime-ftone and fand-ftone. In fome of thefe veins it has been obferved, that when the vein paffes through the lime-ftone, it contains Witherite, or carbonate of barytes; but where it paffes through the fand-ftone, it contains fulphate of barytes, or heavy fpar. It fometimes occurs in a ftatuecal or cellular form, and diffeminated in other minerals.

Witherite is rather a fcarce mineral on the continent. It is a very active poifon. It has not been ufed in the arts in this country. It is probable that it may be employed on the continent in the decomposition of the alkaline fulphates, as foreigners fometimes obtain it from the mines in Yorkfhire in confiderable quantities.

WITHERNAM, in *Law*, a reprifal, or taking of other goods or cattle, in lieu of thofe unjuftly taken and effoined, or otherwife withholden.

The word is compounded of the Saxon *wither*, *contra*, *againft*; and *nam*, *captio*, *taking*. See NAAM.

Where goods are taken by colour of diftreff, and driven to a hold, or out of the county, fo that the fheriff cannot, upon replevy, make deliverance thereof to the party diftrained; in this cafe, the writ of *capias in withernam*, or *de vetito namio*, is iffued, directed to the fheriff, for the taking as many of the party's beafts, as he did thus unlawfully diftrain; or as much goods of his, till he has made deliverance of the frft diftreff: and, therefore, goods taken in withernam cannot be replevied, till the original diftreff is forthcoming.

WITHERNAM, *Homine capto in*. See HOMINE.
WITHERS of a *Horfè*, the juncture of the foulder-bones at the bottom of the neck and mane, towards the upper part of the foulder.

Thefe parts fhould be well raifed and pretty ftrong, for this is a fign of ftrength and goodnefs in the horfe. They keep the faddle from coming forward upon the horfe's fhoulders and neck, which immediately galls and fpoils him. A hurt in this part is very difficult to cure, and, for this reafon, they fhould be lean rather than flefthy, as they are then lefs fubject to be bruifed and hurt by the faddle.

When there are fores on the withers, the caufe muft be looked to, in order to determine a proper cure, and prevent a return. If the hurt be caufed by the largenefs of the faddle-bands, provided that it be not too great, it may be eafily cured by the following remedy: take the whites of fix eggs, beat them with a piece of alum as big as an egg for a quarter of an hour, or till the whole is reduced to a thick fcum or froth; let the fwelling be rubbed well with this mixture, and then covered over with more of the froth; this is to be left to dry on, and the application is to be repeated every ten or twelve hours; notwithstanding that the heat and fwelling remains, this, by degrees, will take place, though not at frft.

If the hurt be great, recourfe muft be had to bleeding; and this may be repeated after two days, if the fwelling and inflammation continue.

If a tumour, with great inflammation, follow a bruife with the faddle-bows, the part affected is to be rubbed with lime-water, and covered with a lamb's skin, the woolly part next the back; after the washing, the ointment, well known among our farriers by the name of the *duke's ointment*, is to be applied; and if the tumour inclines to fuppurate, the ointment muft be wafhed off with a mixture of vinegar and water, warmed, mixed with a handful of falt to every quart of it: an ointment is then to be made of half a pound of populeon, and a quarter of a pound of black foap, and as much

much honey: these are to be thinned with a large glass of spirit of wine, and the part is to be well rubbed with some of this three or four times a-day, covering it afterwards with a lamb's skin. Some use instead of this ointment a poultice made of powder of cummin-seed, linseed-oil, and pigeons' dung, which does as well.

Where these means are not sufficient to remove such tumours or swellings, a more effectual remedy may frequently be found in the blistering liniment.

But wherever matter is formed and distinctly felt by the finger, an opening should be made as near as possible to the most depending part of it, to allow of a free discharge of it, and a rowel be introduced through the whole extent of the cavity, and be frequently moved, and washed with spirits of turpentine; the healing process being promoted by the injection of stimulating washes.

In cases where sinuses are formed, and these means are insufficient for healing the parts, the cure must be performed by making an incision through the whole extent of the hollow parts; dressing them afterwards in such a manner as to keep down the proud flesh, and preserving the wounds clean, as well as aiding the growth of new flesh by proper means. See *ULCER*, and *WOUND*, in *Animals*.

WITHERS of the Bow of a Saddle, in the *Manege*. See *Bow*.

WITHTY, a large species of willow, fit to be planted upon high banks and sides of ditches, within reach of the water, or on the weeping sides of hills.

WITHTY-Cragged, a term sometimes applied to a disease in horses. See *STRAIN*.

WITLAGE, in *Geography*, a town of Westphalia, in the bishopric of Osnabruck; 11 miles E.N.E. of Vorden.

WITLAH, a town of Germany, in the county of Verden; 3 miles S.E. of Verden.

WITLOWIZ, a town of Bohemia, in the circle of Koniggratz; 16 miles N.N.E. of Gitschin.

WITMARSEN, a town of Germany, in the bishopric of Munster; 7 miles W. of Lingen.

WITNESS, TESTIS, a person who certifies or asserts the truth of any fact.

All witnesses are deemed *competent*, who, having the use of their reason, are neither infamous nor interested in the event. See *EVIDENCE*.

Among the Romans, it was a custom to pull or pinch the ears of witnesses present at any transaction; that they might remember it when they were called to give in their testimony. Two eye-witnesses, or *de visu*, not suspected, are to be deemed a conclusive proof.

False witnesses, suborners of witnesses, &c. in England are punished with the pillory; in several other countries, with death. See *PERJURY*, *SUBORNATION*, &c.

In a synod at Rome, under Constantine, in the year 320, it was decreed, that there should be seventy-two witnesses heard, to condemn a bishop; which was called *libra testium*, a pound of witnesses. Accordingly there were seventy-two witnesses heard against pope Marcellinus; who, says the historian, *erant electi libra occidua*.

Anciently there were synodal witnesses, *testes synodales*, in each parish, chosen by the bishop, to inquire into the heresies, and other crimes, of the parishioners; and to make oath thereof on the relics of the saints. See *SYNODALES*.

WITNESS, Attic. See *ATTIC*.

WITNESSES, Trial by, in *Law*, is a species of trial, without the intervention of a jury. This is the only method of trial known to the civil law; in which the judge is left to form in his own breast his sentence upon the credit of the witnesses examined: but it is very rarely used in our law,

except only that when a widow brings a writ of dower, and the tenant pleads that the husband is not dead; this is, in favour of the widow and for greater expedition, allowed to be tried by witnesses examined before the judges; and also in some other cases mentioned by sir Edward Coke, as, to try whether the tenant in a real action was duly summoned, or the validity of a challenge to a juror: who observes, that in every case the affirmative must be proved by two witnesses at the least. Blackst. Com. book iii.

WITNEY, in *Geography*, in the hundred of Bampton, and county of Oxford, England, is a long and irregular, but large and populous market-town, situated 11 miles W.N.W. from Oxford, and nearly 66 in the same direction from London. Through the town runs the little river Windrush. Witney was one of the eight manors given to his cathedral in 1040 by Alwin, bishop of Winchester, in consequence of the suspicion of his improper conduct with Emma, the mother of Edward the Confessor. The queen-mother cleared herself by the fiery ordeal (an experiment of probably little danger), and the bishop made reparation for the scandal he had, although innocent, brought upon his church by a transfer to the clergy belonging to it of eight of his manors. In 1171 the manor was, by bishop Blois, bestowed on his new foundation of St. Cross, near Winchester. In the fifth year of Edward II. Witney became a borough, and continued to send members to parliament till the 33d year of Edward III. when the privilege was declined: it is still, however, called a borough, and governed by two bailiffs. The church, terminating the principal street, is large and handsome, with cross aisles, surmounted by a tower and spire. A free-school was founded here in 1660, and other charitable institutions for the education of youth have lately been formed. Witney has long been celebrated for the manufacture of blankets, of which the weavers were incorporated in queen Anne's reign. When Dr. Plott published his Natural History of Oxfordshire, in 1677, the weaving business employed no fewer than 3000 persons, "from children of eight years old, to decrepit old age;" a number probably not exaggerated, if it be considered, that, in his time, every part of the manufacture was performed by manual labour. But in the latter half of the last century the blanket trade suffered a great defalcation. In 1768 about 500 weavers only were employed, a number which gradually sunk to less than one half: the consequence of which was great distress among the inhabitants. Machinery was introduced into the manufacture, by which one man performed the work of two. The blanket business again revived; but the working hands reaped no benefit from its revival. In 1807, when the price of blankets was five pounds the pair, the workmen earned but twelve shillings per week, the same sum as in 1768, when the pair brought only three pounds. The staple, or blanket-hall, stands in the high street, as does also the town-hall, under which is a place for the market. The rectory of the parish is united with the vicarage, and in the patronage of the bishop of Winchester. The town contains meeting-houses for different descriptions of dissenters. According to the population return of 1811, the houses in the town were 543, and the inhabitants 2722.—Plott's Natural History of Oxfordshire, 1677 and 1705, fol. Beauties of England, Oxfordshire, by J. N. Brewer, 8vo. 1813.

WITRY, a town of France, in the department of the Marne; 6 miles N.E. of Reims.

WITSENIA, in *Botany*, was so named by professor Thunberg, in compliment to Mr. Witsen, "Counsellor to the Chief Magistrate of Amsterdam," whom he styles a most eminent patron and promoter of every kind of science.

Professor

Professor Martyn supposed the honour had been designed for Nicholas Witsen, a writer on shells, who gave one of the earliest accounts of New Holland. (See Phil. Trans. v. 17 and 20.) Thunberg's mission to Japan appears to have been furthered by the influence of the above-named gentleman. We can only rely on him for the propriety of the appellation in question.—Thunb. Nov. Gen. 33. Murray in Linn. Syst. Veg. ed. 14. 83. Schreb. Gen. 37. Willd. Sp. Pl. v. 1. 247. Vahl Enum. v. 2. 47. Mart. Mill. Dict. v. 4. Ker in Sims and Kon. Ann. of Bot. v. 1. 236. Ait. Hort. Kew. v. 1. 109. Juss. 59. Lamarck Illustr. t. 30.—Class and order, *Triandria Monogynia*. Nat. Ord. *Enfatae*, Linn. Ker. *Irides*, Juss.

Gen. Ch. *Cal.* none, unless the upper pair of the *bracteas* be so considered. *Cor.* of one petal, tubular, erect: tube cylindrical, slender at the base, gradually dilated at the top: limb spreading, regular, in six deep, equal, obovate segments. *Stam.* Filaments three, very short, inserted into the mouth of the tube, at the base of three alternate segments of the limb; anthers oblong, erect. *Pist.* Germen superior, roundish, small: style thread-shaped, erect, longer than the tube of the corolla, slightly curved at the extremity; stigma in three short, equal, rather spreading segments. *Peric.* Capsule membranous, of three cells and three valves. *Seeds* several, angular.

Eff. Ch. Calyx none. Corolla with a cylindrical tube; limb in six deep, equal, obtuse segments. Stigma slightly three-cleft. Capsule of three cells, with several angular seeds.

1. *W. maura*. Downy-flowered Witsenia. Thunb. Nov. Gen. 34. t. 2. f. 1. Fl. Cap. v. 1. 255. Willd. n. 1. Vahl n. 1. Ait. n. 1. Redout. Liliac. t. 245. (*Antholyza maura*; Linn. Mant. 175.)—Flowers terminal, in pairs. Outer segments of the corolla externally downy.—Native of the shady sides of hills, at the Cape of Good Hope, flowering in April and May. Sent to Kew by Mr. Masson, in 1790, but it does not appear to have blossomed in that collection, nor elsewhere in Europe, M. Redoute's fine figure being made from a dried specimen, aided by description. The root is perennial and woody. *Stem* shrubby, erect, more or less branched, two feet high, compressed; naked in the lower part, and appearing as if jointed, from the scars left by former foliage; leafy above. *Leaves* numerous, alternate, sessile, two-ranked, equitant, four or five inches long, compressed, striated, acute, entire. *Flowers* in pairs at the extremities of the short terminal branches, crowded, more or less numerous, into a corymbose tuft. *Corolla* two inches long: its tube yellow at the base, dark blue for a considerable extent in the upper part; limb yellow, scarcely spreading, full half an inch long, clothed externally with dense shaggy pubescence of a very peculiar kind, confined to the tips of the inner segments.

2. *W. corymbosa*. Corymbose Witsenia. Ker in Curt. Mag. t. 895. Ait. n. 2. Sm. Exot. Bot. v. 2. 17. t. 68.—Corymb many-flowered. Corolla externally smooth.—Native of the Cape of Good Hope. Raised from seed by G. Hibbert, esq. in 1803. A green-house plant, flowering in spring and autumn. The stem is shrubby, from four to six inches high. *Leaves* like the last, but only half the size, somewhat glaucous. *Flowers* very numerous, bright blue, in a forked corymbose, compound panicle, supported by a long stalk, at first terminal, but soon becoming lateral. *Bracteas* two pair at the base of each flower, concave, obtuse. *Corolla* about an inch long, including its horizontal limb.

3. *W. ramosa*. Branching Witsenia. Thunb. Fl. Cap. v. 1. 256. Vahl n. 2. (*W. fruticosa*; Ker in Ann. of

Bot. v. 1. 237. *Ixia fruticosa*; Thunb. Diff. n. 1. t. 1. f. 3. Lamarck Illustrat. t. 31. f. 4. Linn. Suppl. 93.)—Stem much branched. Corolla externally smooth; its tube capillary, twice the length of the limb.—Native of hills at the Cape of Good Hope, flowering in October, November, and December. The stem is a span high at most, remarkably woody, repeatedly branched in a corymbose manner; naked below; the branches compressed, two-edged, knotty or scarred as if jointed, leafy at their extremities. *Leaves* equitant, two-ranked, linear, narrow, one and a half or two inches long, rather glaucous; reddish at the base. *Flowers* terminal, very few together, if not quite solitary, blue, remarkable for the length and slenderness of their tube, which sometimes measures nearly two inches; the limb is rather less spreading, and more bell-shaped, than that of *corymbosa*. *Bracteas* membranous, elongated, brownish.

4. *W. pumila*. Dwarf Witsenia. Vahl n. 3. (*Ixia pumila*; Forst. Comm. Gott. v. 9. 20. t. 2. *I. magellanica*; Lamarck Illustr. v. 1. 109. *Moræa magellanica*; Willd. Sp. Pl. v. 1. 241, excluding Cavanilles' synonym. *Tapeinia*, Juss. 59.)—Stems simple, single-flowered.—Gathered by Forster, Commerçon, and others, at the straits of Magellan. The root is perennial, long, branched, bearing dense tufts of numerous, simple, leafy stems, an inch or inch and a half high. *Leaves* crowded, two-ranked, awl-shaped, compressed, strongly ribbed, about an inch long. *Flowers* whitish, small, solitary, nearly sessile, among the uppermost leaves, which form a kind of sheath, but each appears to have also a bivalve sheath, or pair of bracteas, which are permanent. Capsule brown, with rather rigid, emarginate valves.

Mr. Ker observes, that this is the only genus of its natural order whose habit is in any degree shrubby. He mentions, in the Annals of Botany, another species, by the name of *partita*, seen by himself in Mr. Hibbert's herbarium; but without any indication of its characters, so that we have no means of knowing how it differs from the foregoing.

WITSIO, in *Geography*, a town of Sweden, in the province of Schonen; 28 miles N.N.W. of Christianstad.

WITT, JOHN DE, in *Biography*, the son of a burgo-master of Dordrecht, was born in 1625, and educated in various useful sciences, so as to excel in a knowledge of jurisprudence, politics, and mathematics, in the latter of which he was so great a proficient, that he wrote a treatise on the elements of curve-lines, which was published under the inspection of Francis Schooten. For further improvement he spent some years in travel, and upon his return was elected to his father's post of pensionary of Dordrecht. Attached by his descent to the principles of republicanism, and jealous of the house of Orange, he opposed the elevation of this house, and dissuaded the province of Zealand from conferring the office of captain-general upon the young prince, William III. His conduct in this business was much approved, and he was henceforth regarded as at the head of the political administration of the United Provinces. This was a period peculiarly critical and interesting. The war with the new English republic distressed the states; it was injurious to their trade and finances; and presented to the Orange party a favourable opportunity for advancing prince William to the power and dignities possessed by his ancestors. Peace at length became absolutely necessary; and one of the articles concluded upon in 1654, and dictated by Cromwell, was the perpetual exclusion of the prince of Orange from the high offices formerly held by his family. This article was agreed to by the states of Holland alone, and when De Witt drew up a declaration for divulging it,

it, some of the provinces censured it, and charged the anti-Orange party with having suggested it to Cromwell. The province of Holland, however, carried the point, and the general tranquillity was little disturbed. De Witt now directed his attention to the state of the finances, and succeeded in reducing the interest of the public debt, and persuading the people to acquiesce in this measure. The restoration of Charles II. was generally agreeable to the United States, and more especially to the Orange party: but the restored sovereign soon declared his dissatisfaction with De Witt, because he had been hostile to the elevation of the house of Orange. From this time, the Dutch statesman favoured the politics of France more than those of England. At length a war took place between the Dutch and English in 1665; during the progress of which De Witt was often unpopular, though he was the main spring which kept in action the resources of the state, and remedied every calamity. Peace with England in 1667 developed the ambitious projects of Lewis XIV. in taking possession of the Spanish Netherlands; and the alarm which this measure produced in the United Provinces gave occasion to the friends of the house of Orange to propose the elevation of the young prince to the dignities which his family had possessed. De Witt, with a view of counteracting this purpose, obtained a resolution on the part of the states of Holland for separating the offices of captain-general and stadtholder (see WILLIAM III.), which resolution gave great offence to the other provinces, and rendered De Witt, with whom it was supposed to have originated, extremely unpopular. Sensible, however, of the dangers arising from French ambition, he concurred in the triple alliance between England, Sweden, and the United Provinces, concluded, in 1668, by himself and sir William Temple. The states of Holland were so satisfied with his conduct, that they nominated him for five years more to the office of their pensionary, which he had already occupied for fifteen years. Confiding in the triple alliance, and the subsequent peace of Aix-la-Chapelle, he again indulged his jealousy of the Orange party and a standing army, and considered the danger from France as a secondary object. But the ambition of Lewis had no bounds; the unprincipled Charles II. could not be relied upon; the triple alliance was set aside; and the English cabinet joined the French in direct war with the United Provinces; so that in the year 1672 a French army made an irruption into the territories of the states, and threatened to overwhelm the whole country. The anti-Orangists were then compelled to confer the chief command on William. The conduct of the French had been so atrocious, that every person who had manifested the slightest attachment to their politics was charged with treason. De Witt became the object of public indignation, and to him were ascribed all the calamities which were felt or feared. Four assassins attempted his life, as he was returning home from an assembly of the states of Holland, attended by a single servant; but though he received many wounds, none of them were mortal. One of the assassins was taken and executed; but such is the influence of party, the friends of the house of Orange regarded the wretch as a martyr. Cornelius de Witt, on his return from the fleet, where he had served as deputy of the states, narrowly escaped from a similar attempt. The prince was now elevated to the stadtholderate; and the pensionary, as soon as he was recovered from his wounds, visited him with congratulation on the event, but was coolly received. Finding that, as he was become an object of the public hatred, he could be no longer of any service, he requested permission from the states of Holland to resign his office, which was granted him upon the most honourable terms. His brother was at this time imprisoned among common

felons at the Hague, under a charge, preferred by a person of infamous character, of having formed a plot against the life of the prince of Orange. On his trial he was put to the torture, in the most cruel form of applying it; but though he endured the most aggravated sufferings, protesting his innocence, and citing his judges before the tribunal of God for their treatment of him, they pronounced sentence, which deprived him of all his dignities, and banished him for life from the province. Although no criminal charge was brought against John de Witt, the enemies of the family resolved that neither of the brothers should escape with life. Deceyed by a fictitious message to visit his brother Cornelius in the prison, a furious mob assembled to prevent his return. The states of Holland ordered a guard to disperse the people, and requested some companies of horse and foot to be sent from the camp of the prince of Orange. But the commanding officers were inveterate in their enmity against the De Witts; and the inflamed populace, not restrained from executing their bloody purpose, forced open the doors of the prison, dragged out the two brothers, and inhumanly massacred them. This catastrophe took place in August 1672, John de Witt being in the 47th year of his age. Although the states of Holland pronounced the deed to be detestable, and requested the stadtholder to take proper measures for avenging the death of these two brothers, it was pretended that it would be dangerous to inquire into a deed in which the principal burghers of the Hague were concerned, and therefore none of the murderers were brought to justice. It should, however, be recollected, that the prince never spoke of this massacre without the greatest horror.

The character of De Witt has been described in honourable terms by sir William Temple, who knew him well, both in private life and in his public station. He speaks of him as a person of indefatigable application, of invincible resolution, of a sound and clear judgment, and of irreproachable integrity, inasmuch, that if he was blinded in any respect, it was in consequence of his passion for promoting what he thought the welfare of his country. He bears testimony to the pensionary's knowledge of the interests of foreign courts, though he did not make sufficient allowance for the treachery of princes, or rather their ministers, and was thus misled with regard to the ambitious views of France. If he had any wrong bias in his political conduct, it was that of an hereditary jealousy and dislike of the house of Orange, which led him in some cases to act rather as a party leader than an unprejudiced patriot. No man could be less influenced than De Witt by views of avarice or ostentation. His manners and appearance were adapted to the ancient simplicity and frugality of his country, even in the height of his power. When his papers and private letters were submitted to a rigorous scrutiny after his death, nothing was discovered that could impeach his integrity. When one of the commissioners was asked what they had found in De Witt's papers; "What (said he) could we have found—nothing but probity!" As a man of business, he was scrupulously attentive to order and method; and when he was once asked, How he was able to transact such a multiplicity of affairs? he replied, "By doing only one thing at a time." Mod. Un. Hill. Gen. Biog.

WITTBACH, in *Geography*, a river of Germany, which rises near Hackenburg Sayn, and after a circuitous course runs into the Rhine, about a mile below Neuwied.

WITTELM, a small island in Steinhuder lake, with a fort; 3 miles N. of Hagenburg.

WITTELOHE, a town of Germany, in the county of Verden; 10 miles S.E. of Verden.

WITTEM, a citadel of France, in the department of the Roer. It heretofore gave name to a lordship, wholly surrounded by the duchy of Limburg; 6 miles S.E. of Aix-la-Chapelle.

WITTEN, in *Commerce*, a money of account at Pernau and Stettin, &c. At Pernau a current rix-dollar is reckoned at 60 wittens, or 75 copecks; and an Albert's rix-dollar is estimated at 80 wittens, or 100 copecks; a Pernau mark is worth 3 wittens; a Lettish mark = 2 wittens; and 4 wittens = 5 copecks. At Stettin the rix-dollar was formerly divided into 36 shillings current, 72 shillings Sundish, or 144 wittens; which monies of account are now nearly discontinued.

WITTEN, in *Geography*, a town of Germany, in the county of Mark; 7 miles S.E. of Bockum.

WITTEN *See*, a lake of the duchy of Bremen; 10 miles S.E. of Bremen.

WITTENA-GEMOTE, among our *Saxon Ancestors*, a term literally signifying a council, or assembly of sages, or wise men; applied to the great council of the land, in later days called *parliament*; which see. See also GEMOTE.

In the Saxon times, this was the chief court of the kingdom, where all matters, both civil and criminal, and those relating to the revenue, were determined. In civil and criminal matters, it was a court, in the first instance only, for facts arising in the county where it sat; but it heard and determined causes from all other counties by way of appeal. To this court were summoned the earls of each county, and the lords of each leet, as also the representatives of towns, who were chosen by their burgesses. This was the legislative and supreme judicial assembly of the Anglo-Saxon nation. As highest judicial court of the kingdom, it resembled our present house of lords; and in those periods, when the peers of the realm represented territorial property rather than hereditary dignities, the comparison between the Saxon wittena-gemote, and the upper house of our modern parliament, might have been more correctly made in their legislative capacity. The German states are recorded by Tacitus to have had national councils, and the continental Saxons are also stated to have possessed them. When the Cyning was only the temporary commander of the nation for the purposes of war, whose function ceased when peace returned, the wittena-gemote must have been the supreme authority of the nation; but when the Cyning became an established and permanent dignity, whose privileges and power were perpetually increasing till he attained the majestic prerogatives and widely-diffused property which Athelstan and Edgar enjoyed, the wittena-gemote then assumed a secondary rank in the state. This council was called by different names, and it was composed of persons who were denominated witan from their presumed wisdom, and with reference to their rank and property eadigan, (the wealthy,) optimates, principes, primates, proceres, cucionatores anglia, &c. The gemotes of the witan, without doubt, varied, as our parliaments vary, in the number and quality of the persons who from time to time attended. Most of those whose names are subscribed to councils or charters, and who appear to have been the witan who constituted the gemote, have some titles after their names; but there are some gemotes which have names without any addition. It is not easy to ascertain all the qualifications which entitled persons to a seat in the wittena-gemote. There is, however, one curious passage, cited from the *Book of Ely*, in *Gale's Script.* vol. i. p. 513, which has been alleged by some writers as ascertaining that a certain amount of property was an indispensable requisite, and that acquired property would answer this purpose as

well as hereditary property. The possession stated to be necessary to constitute one of the proceres was forty hides of land. The incident to which this passage refers occurred in the reign of Edward the Confessor. It related to the brother of an abbot, who, though nobly born, could not be reckoned among the nobility of the kingdom, because he had not an estate of forty hides of land; and, therefore, he was refused by a lady, whom he sought in marriage, till his estate was increased to that magnitude by grants of land from his brother. This passage merely proves, that a certain portion, and that a very large one, of landed property *in dominio* was a necessary qualification, under the Anglo-Saxon government, to admit any person to the "rank and degree of nobility." But no argument, says lord Littelton, can be justly drawn from hence, that, in order to be qualified for a place in the Saxon great council, or wittena-gemote, it was requisite to be lord of forty hides of land. Such a notion does not agree with any accounts that are given us of that assembly in the writings or records of those times. By a passage in the preface to Ina's laws, as translated by Wilkins, it appears, that the Saxon legislature was composed of the king, *cum omnibus suis senatoribus*, which senators Littelton supposes to have been the "nobility of the kingdom," such as afterwards formed the ordinary council of lords under our kings of Norman race; et *cum senioribus sapientibus populi sui*, by whom he understands the deputies or representatives of the people, either by election or magistracy; et *cum multa etiam societate ministrorum Dei*, which words evidently denote the inferior clergy, mentioned by Eadmer as present in the parliaments of those times. It appears also, by a paragraph in Spelman's *Councils Sub. Ann.* 855, that the Saxon constitution required not only the "presence," (see *Borough*,) but the "approbation of the people," to the enacting of a law; though, by way of marking the distinction between these and the higher orders of the state, the nobility alone set their hands to the act. "Whoever," says sir John Fortescue Aland, who was very learned in the Saxon language and legal antiquities, in his preface to the book of chancellor Fortescue on the difference between an absolute and limited monarchy, "carefully and skilfully reads the Saxon laws, and the prefaces or preambles to them, will find, that the commons of England always in the Saxon times made part of that august assembly." In a passage occurring in lib. iii. f. 56. of William of Malmesbury, we have an express declaration, that by the Saxon constitution established in England, the "people," as well as the nobles, had a right to be called to the "General Assembly" upon affairs of great moment, and to join in the "edicts" made there; so that, without "their consent," the succession to the crown could not be settled. The term *Senatus* used by this historian denotes the ordinary assembly of the nobles, which he distinguishes from the "people;" but he supposes that the latter ought to be joined to the former, in order to compose the entire legislature and great council of the nation, upon extraordinary occasions. This was agreeable to the custom ascribed by Tacitus to the Germans, from whom they sprung; "De minoribus rebus principes consultant, de majoribus omnes; ita tamen, ut ea quoque, quorum apud plebum arbitrium est, apud principes pertractantur." See *Borough*.

It has been, among constitutional antiquarians, an interesting question, whether they who possessed this quantity of land had thereby the right of being in the wittena-gemote; or whether the members of this great council were elected from the territorial proprietors, and sat as their representatives? One person is mentioned by Mr. Turner (*ubi infra*),

whose

whose designation seems to have the force of expressing an elected member. Among the persons signing to the act of the gemote at Clofeshoe in 824 is, "Ego Beonna *electus* consent. et subscrib."

The members of the gemote were convened by the king's writ, of which many instances occur; and the times of their meeting seem to have been usually the great festivals of the church, as Christmas, Easter, and Whitsuntide; but of these Easter, being most frequently mentioned, seems to have been the favourite period. Their meetings, however, were not absolutely restricted to these seasons. The place of their assembly was not fixed. Perhaps this might depend on the king's residence at the time, and might have suited his convenience. Our monarchs seem to have maintained their influence in the wittena-gemote by their munificence. The king presided at this council, and sometimes, perhaps always, addressed them. In 993 we have an account of a royal speech. One of their duties was to elect the sovereign, and to assist at his coronation. Another was to co-operate with the king in making laws. The wittena-gemote appears also to have made treaties jointly with the king. Many instances occur to this purpose. The treaty, printed in Wilkins's *Leges Anglæ-Saxonicæ*, p. 104, is said to have been made by the king and his witan. They are also mentioned as assisting the king in directing the military preparations of the kingdom. Impeachments of great men were made before the wittena-gemote. At these councils grants of land were made and confirmed; and the wittena-gemote frequently appears in the Saxon remains, as the high court of judicature of the kingdom, and it exercised power over the public guilds of the nation. The lands of the Anglo-Saxons, the burghs, and the people, appear in all the documents of our ancestors, as subjected to certain definite payments to the king as to their lords; and by a custom, whose origin is lost in its antiquity, among the Anglo-Saxons, all their lands, unless specially exempted, were liable to three great burdens, the building and reparation of bridges and fortifications, and to military expeditions. But what we now call taxation seems to have begun in the time of Ethelred, and to have arisen from the evils of a foreign invasion. Thus the payment of 10,000*l.* to the Danes to buy off their hostility, mentioned by Henry of Huntingdon, and those which followed, are stated to have been ordered by the king and the wittena-gemote. Under sovereigns of feeble capacity, the wittena-gemote seems to have been the scene of those factions, which always attend both aristocracies and democracies, when no commanding talents exist to predominate in the discussions, and to shape the council. Turner's *Hist. of the Anglo-Saxons*, vol. ii. book 10. Littelton's *Hist. Henry II.* vol. iii.

WITTENBERG, in *Geography*, a town of Saxony, and capital of a circle or district, situated on the side of the Elbe, over which is a ferry: it is the head town of the electoral circle, the seat of an aulic judicature, of the assize, as also a consistory, together with that of the general superintendency of the electoral circle, a spiritual inspection, the circle amt, and a famous university, founded in the year 1502, at which, in 1517, the Reformation took its rise by means of Martin Luther. This town is not large, but fortified. The old citadel was formerly the electoral residence; near it stands an arsenal. In the large round tower are kept the archives of the electoral and princely houses. The university library is kept in what was formerly an Augustine cloister. The first founder of the town of Wittenberg was Bernard, duke of Saxony. In the year 1547, it was taken by the emperor Charles V.; in the year 1756, it was possessed by the Prussians, who also broke down a

bastion of the fortifications; 60 miles N. of Dresden. N. lat. 51° 53'. E. long. 12° 46'.

WITTENBERG, a town of Prussia, in Natangen; 8 miles N. of Heilberg.—Also, a town of the duchy of Lauenburg, on the Elbe; 8 miles W. of Lauenburg.

WITTENBERGEN, a town of Brandenburg, in the Mark of Pregnitz; 6 miles S.S.W. of Perleberg. N. lat. 53° 2'. E. long. 11° 50'.—Also, a town of the duchy of Holstein; 8 miles S.W. of Lutkenburg.

WITTENBURG, a town of the duchy of Mecklenburg; 17 miles W. of Schwerin.

WITTENHALL, a township of England, in Staffordshire; 2 miles N.E. of Wolverhampton.

WITTENHAUSEN, a town of the duchy of Holstein; 5 miles W. of Oldeburg.

WITTENSTEIN, a town of Prussia, in the province of Natangen; 10 miles S.S.E. of Königsberg.

WITTGENAU. See WITGENAU.

WITTHOEC, a town of Africa, in the country of Cape Lopez Gonfalso; 30 miles N. of Olibato.

WITTICHSTHAL, a town of Saxony, in the circle of Erzgebirg; 7 miles S. of Schwartzenberg.

WITTINGEN, a town of Westphalia, in the principality of Luneburg Zelle; 27 miles E. of Zelle.

WITTLÉSEE MERE, a lake of England, in the county of Huntingdon; 4 miles S. of Peterborough.

WITTLICH, a town of France, in the department of the Rhine and Moselle; 16 miles N.E. of Treves. N. lat. 50° 4'. E. long. 6° 52'.

WITTMUND, a town of East Friesland, on the Harle; 7 miles S.E. of Eßens.

WITTOBA, in *Hindoo Mythology*, is a name of the god Vishnu in one of his numerous *descents*, or *avatars*, as they are called. Some account of these avatars is given under our article VISHNU. This, now under consideration, was one of inferior importance; and not, it is said, of very ancient occurrence, and therefore not described in the Puranas, unless it be in the one supposed to be more modern than the rest, which is entitled Maha Bhagavat. (See PURANA, and SRI BHAGAVATA.) A splendid temple is dedicated to the worship of Wittoba, or Vishnu, at Panderpoor, a town of great respectability on the river Beemah, about 100 miles to the south-eastward of Poona. The manifestation is said to have taken place there. He is there represented sculptured in stone, of the size of a man, standing with his feet parallel to each other; his hands upon his hips, the fingers pointing forward, his thumbs backward. Two of the wives of Vishnu in his avatars of Krishna accompanied him in this; these were Rukmeni and Satyavama, and they have smaller temples at Panderpoor, besides their lord's. (See KRISHNA, RUKMENI, and SATYAVAMA.) Images of Wittoba are common in the Mahratta country, generally of clumsy manufacture. Several representations of Wittoba and his wives are given in the Hindoo Pantheon, from casts and pictures. That work contains also a history of the avatars, and many particulars respecting it.

WITTORF, in *Geography*, a town of Germany, in the county of Verden; 10 miles S.S.E. of Rotenburg.

WITTOW, a town on a peninsula at the northern extremity of the island of Usedom, near Artona, an ancient fortress destroyed by the Swedes. N. lat. 54° 44'. E. long. 13° 27'.

WITTSTOCK, a town of Brandenburg, in the Mark of Pregnitz; 47 miles N.N.W. of Berlin. N. lat. 53° 10'. E. long. 12° 39'.—Also, a town of Brandenburg, in the New Mark; 12 miles N. of Custrin. N. lat. 52° 49'. E. long. 14° 50'.

WITWALL, in *Ornithology*, a common English name for the great spotted wood-pecker, the *picus varius major* of authors.

WITZELRODE, in *Geography*, a town of Germany, in the county of Henneberg; 3 miles E.N.E. of Salzen-gen.

WITZELSTORFF, a town of Austria; 4 miles S.E. of Hoffmarckt.

WITZENBURG, a town of Westphalia, in the bishopric of Hildesheim; 6 miles S.E. of Alfeld.

WITZENHAUSEN, a town of Germany, in the principality of Hesse Rhinfels; 13 miles E. of Cassel. N. lat. $51^{\circ} 10'$. E. long. $9^{\circ} 48'$.

WIVELISCOMBE, a large market-town in the hundred of West Kingsbury, and county of Somerset, England, is situated in a valley, at the distance of 11 miles W. from Taunton, 25 miles W. from Somerton, and 156 miles W. by S. from London. It appears to have been of some note under the Romans, though not distinguished in their annals as a station or military post. In the earlier part of their transactions in this island, they had a large castrum, or encampment, on a hill about a mile eastward from the town, which still is called the castle. Its summit contains about twelve acres; and though mostly covered with coppice-wood and bushes, the vestiges of fortifications, and the foundations of buildings, are yet discernible on its surface. Part of the fosse, which is very deep, and extended round the hill, has been destroyed by the working of a quarry. Near the centre of the area, a great number of Roman coins of various emperors were discovered in the beginning of the last century. The Danes, during their incursions into this county, availed themselves of this castle, and after their departure, the Saxons, recovering their tranquillity, transplanted themselves to the adjacent vale, and gave their new habitations the name of Wiveliscombe. From this time it progressively became of importance, constituted the head of a large lordship, and was always held by the Saxon kings, till Edward the Confessor granted all the lands to the church of Wells. The bishops of that see had a stately palace here for nearly three centuries: it is now in ruins; a workhouse, erected in 1735, occupies a part of the ancient site. The town now consists of seven irregular streets: it is governed by a bailiff and portreeve, who are annually chosen in May. Here were formerly two markets, one on Tuesdays, the other on Saturdays; the latter only is now retained, with three annual fairs. A considerable woollen manufacture has been carried on for more than two hundred years, and still flourishes; the chief articles made are, blanketings, knap-coatings, kerseys and other coarse cloths, shrouds, ermine, and baize. Many of these are sent to London, Bristol, and Exeter, for home consumption, and for exportation to Spain and Guernsey. The church is a plain structure, and consists of a nave and two aisles, with a tower and spire at the west end. The parish besides the town includes four small hamlets, and according to the population return of the year 1811 contains 567 houses, and 2550 inhabitants.—Collinson's History, &c. of Somersetshire, vol. ii. 1791.

WIVENHOE, a village of England, in the county of Essex, situated on the river Coln; it is the harbour of Colchester, and here is a custom-house. The oysters, called Colchester oysters, are barrelled in this place. In 1811, the population was 1046.

WIZE, a river of England, in the county of Cumberland, which runs into the Wever.

WIZNA, a town of the duchy of Warsaw; 88 miles N.E. of Warsaw.

WIZUNY, a town of Lithuania; 20 miles N.N.E. of Wilkomiers.

WIZZARD, in *Agriculture*, a term applied in Norfolk to any particular sort of cart for farm-work.

WIZZENED, a term provincially applied to signify withered or shrivelled, as hay.

WLADISLAW, in *Geography*, a town of Moravia, in the circle of Iglau; 12 miles S. of Meferitsch.

WLADISLAW, or *Inowroslaw*, a town of the duchy of Warsaw, and capital of a palatinate of the same name, on the Vistula: the see of the bishop of Cujavia, removed from Kruswica in 1173; 108 miles N.W. of Warsaw. N. lat. $52^{\circ} 35'$. E. long. $18^{\circ} 35'$.

WLODOWA, a town of Austrian Poland; 18 miles N.E. of Chelm.

WLODZIMIERZ, a town of Poland, in Volhynia, on the Bog; the see of a Greek bishop, united to the church of Rome; 48 miles W. of Luckow.

WOAD, in *Agriculture*, a plant cultivated in the field for the use of the dyers. It is a plant which has a strong thickish fibrous root, which penetrates deep into the soil, and which is principally raised for the use of the leaves, which, after being properly manufactured, are made use of in the art of dyeing to produce a blue colour, as well as the basis of black, and some others.

Soil.—It is evident from the nature of its root that it requires a soil which has much depth or staple, and which is perfectly fresh, such as those of the rich, mellow, loamy, and deep vegetable kind. Where this sort of culture is carried to a considerable degree of perfection, as in Lincolnshire, the deep, rich, putrid, alluvial soils on the flat tracts extending upon the borders of the different large rivers are chiefly employed for the growth of this sort of crop; and it has been shewn by repeated trials that it answers most perfectly when they are broken up from a state of sward immediately for it. In some places, it is the practice to take lands of this description at high prices, for the purpose of breaking them up and growing it upon them for two or three years; on the more low rich soils, for four years, but on those of less fertility only for three; and in some, which are more elevated and exposed, two are considered sufficient. For this sort of culture, people are employed, who move from place to place, and form a sort of colony. Mr. Cartwright, in the above county, has however found, that it is capable of being confined to one spot with equal or greater success, by having a sufficient extent of ground for changing the place of its growth as may be necessary, and for appropriating an adequate proportion annually to the raising of the plant, by which the houses and expensive machinery that are necessary for its preparation may be kept constantly and regularly employed in the business.

Preparation.—In order to prepare the land for this crop, it is advised by some to plough it up with a good deep furrow, immediately before the winter commences, laying it in high narrow ridges, to have the full effect of the frosts; and early in the spring to give another ploughing in the contrary direction, leaving the ground in the same kind of ridge as before. When it has remained in this state some length of time, and weeds appear, it should be well harrowed down with a heavy harrow, repeating the operation so as to render it perfectly fine and clean. About the beginning of June a third ploughing should be given to the full depth with a narrow furrow, and the land be afterwards well harrowed down as before; the fourth or final ploughing being given towards the beginning of July, in a light manner, leaving the surface as even as possible for the seed. But some take much less trouble in the business of preparation.

tion. In cases where the soils are sufficiently dry, only breaking them up early in the month of February; and where the contrary is the case, deferring it to a later period, taking care to plough the land in a perfect manner to the depth of five inches, or more; and that the furrow-slices may be well turned, laid flat, and nicely jointed, a person is employed with a spade for the purpose of adjusting them. This prevents the grassy matters from rising in the seams. When this has been done, the surface is repeatedly harrowed over, to raise a sufficient depth of good mould for the drill to work in; and before the seed is put in a roller is passed over the land.

It is probable, however, that this method is inferior to the former, as the land is not brought nearly to so fine a state of mould, or the grassy material so effectually covered and destroyed, from which injury may be done to the woad plants in their early growth.

But a method which is equally effectual with the first, more expeditious, and which has a superiority over it, in more completely destroying grubs, insects, and other vermin, which are apt to feed on the plants in their early growth, is that of paring and burning. This is, however, chiefly practised where the sward is rough, and abounds with rushes, sedge, and other plants of the coarse kind, but might be had recourse to on others, with vast benefit.

Where the latter modes are made use of as soon as the seed has been put in, the land should be carefully drained by forming grips in suitable directions, as wherever water stagnates, the woad plants are liable to be injured or destroyed.

Seed.—In respect to the seed, it should be collected from ground that has been left covered with the best plants from the preceding season, as they only run up to stem and form seeds in the second year; and in order to have good seed, the leaves should not be cropped at all or but once, the stems being suffered to remain till the seeds in the husks become perfectly ripened; which is shewn by their attaining a brownish-yellow colour, and the pods having a dark blackish appearance. It should then be gathered as soon as possible, by reaping the stems in the manner of grain, and then spreading them in rows thinly upon the ground if the weather be fine, when in the course of a few days they will be in a state to be threshed out from the husks or pods. When they are suffered to remain too long, the pods are liable to open, and shed the seed. Although the pod in which the seeds are contained is of a large size, the seeds are less than those of the turnip. New seed, where it can be procured, should always be sown in preference to such as has been kept for some time; but when of the latter kind, it should be steeped for some time before it is put into the ground.

In regard to the quantity of seed which is necessary, it must be regulated by the soil, and the manner in which it is sown. Where the drill is employed, less will be required than in the broad-cast method. It has been found that a rood of land, where the crop is good, will in general afford seed sufficient for eight or ten acres; and in some cases, in the broad-cast method, five or six bushels are made use of to the acre. In Kent they use ten or twelve pounds to the acre.

Sowing.—The time of sowing crops of this nature must be regulated, in some degree, by the mode of preparation that has been employed. Where the first of the above methods has been followed, it will be much later than in the other cases. But early sowing is in general to be preferred, as there will be less danger of the plants being injured by the attacks of the fly or grub. Where the weather is suitable, and the land in a proper state of preparation, the

seed may be sown in the latter end of February or March, continuing the sowings, in different portions of land, till about the middle of May, at suitable intervals of time to vary the times of cropping the leaves of the plants. The late sowings are commonly executed about the latter end of July, or early in the following month at the farthest.

With respect to the manner in which the seed is sown, it differs according to the nature and state of preparation of the land. Where it is in a fine state of mould, the drill or row method is the method mostly practised, which is by much the best, as by it the plants may be kept more easily clean and free from weeds, becoming more strong and vigorous, from the earth being more stirred about the plants: but where the contrary is the case, the broad-cast mode is generally followed; but which does not by any means admit of the plants being kept so free from weeds, or the mould so well stirred about the roots of them.

Where the first method is had recourse to, the seed is sown by a drilling-machine, such as is used for turnips, in equidistant rows, eight or nine inches apart, covering it in, either by means of a harrow attached to the implement, or by passing a light common harrow over the ground afterwards, once in a place, raking off any clods that may be present to the sides, or into the furrows: but in the latter mode, it must be dispersed by the hand in as equal a manner as possible, over the whole of the land, being then barrowed in by a light harrow, so as to leave the land in as even and level a state as possible. The ground is frequently rolled afterwards, that the surface may be left as even as possible.

In favourable seasons with good seed, the plants mostly appear in the course of a fortnight, when much attention should be paid to see that they are not destroyed by the turnip-fly, or the frosts in those of the more early sowings; as, where that is the case, the land should be immediately re-sown; as in some cases it is not uncommon to sow the greatest part of the crop two or three times over. In the very late sowings, where the crops rise thin on the ground, it is sometimes a practice to give a better plant by forming holes with a hoe in the vacant spots, and directing seeds to be dropped into them by the hand by women or children. This is the case with the late spring-sowings till the beginning of June, or a later period.

Culture while growing.—From much of the goodness of the woad plants depending on the luxuriance of their growth, and the thickness of their leaves, it is necessary to bestow great attention in the culture of the crop while growing. It is advised that the spring-sown crops, as well as those that are sown in the latter part of the summer, should have the first hoeings given them as soon as the plants are fully distinguishable above the ground, as by this means the weeds will not only be prevented from retarding the vegetation of the plants, but these by being thinned out to greater distances be more at liberty to advance and become vigorous in their first or early growth, which is a matter of much consequence to the success of the crop; and second hoeings should be given in the course of four or five weeks afterwards, when the plants should be thinned out to the full distances at which they are to stand, which may be six or seven inches, or more, according to the goodness of the soil, constantly leaving sufficient room to prevent the plants from being in any way crowded. The work is sometimes executed in much the same manner as for turnips, by hand-hoes; but in others by small short spuds, used with one hand, while the other is employed in clearing away the weeds; the labourers, mostly women and children, kneeling while they perform the work. When this work has been done, nothing further is necessary till the first cropping of the

the leaves has been performed, when the plants should be again immediately well weeded; and after each cropping the same operation be had recourse to; the extent of crop cleared in the day being, in most cases, weeded before night.

With the late-sown crops, after the second weeding in October, nothing further will be requisite till the spring, about the middle of April, when the work should be again well executed, the mould being completely stirred about the roots of the plants, that they may derive the fullest benefit from the operation. This will be sufficient to keep them clean till the taking of the first crop; after which they must be again weeded, and the same operation be had recourse to after each cropping of the leaves, as in the above case.

In respect to the business of gathering the crops with the spring-sown ones, the leaves will generally be ready to be gathered towards the latter end of June, or beginning of July, according to the nature of the soil, season, and climate; but for those put in at a later period in the summer, they are often fit to be gathered earlier. This business should, however, constantly be executed as soon as the leaves are fully grown, while they retain their perfect green colour, and are highly succulent; as when they are left till they begin to turn pale, much of their goodness is said to be expended, and they become less in quantity, and of an inferior quality for the purposes of the dyer. In favourable seasons, where the soils are rich, the plants will often rise to the height of eight or ten inches; but in other circumstances they seldom attain more than four or five: and where the lands are well managed in the culture of the plants, they will often afford two or three gatherings, but the best cultivators seldom take more than two, which are sometimes mixed together in the manufacturing of them. It is necessary that the after-croppings, when they are taken, are constantly kept separate from the others, as they would injure the whole if blended together, and considerably diminish the value of the produce. It is said that the best method, where a third cropping is either wholly or partially made, is to keep it separate, forming it into an inferior kind of woad.

Upon an acre of land, when well managed, in favourable seasons, the produce is mostly from about a ton to a ton and a half. The price varies considerably; but for woad of the prime quality, it is often from twenty-five to thirty pounds the ton, and for that of an inferior quality six or seven, and sometimes much more.

Seeding-Crops.—With such parts of the crops as are reserved for seed, it is a practice with some to crop the leaves two or three times the first year, and then leave the plants to run up to seed in the following one; but it is a better practice to only remove the side-leaves, as in this way the plants are less weakened, and the produce of the seed much increased. The plants are likewise sometimes fed down by sheep during the winter season; but this, from its tendency to weaken them, is equally improper and prejudicial.

Preparation of for the Dyer.—The woad, after it has been gathered, undergoes several processes to prepare it for the dyer; but in the improved method it is conveyed in one-horse carts, so contrived as to be lifted from the axis, and, by folding doors in the bottoms, to discharge their contents upon the floor above the mill, on being hoisted up to their proper situation: round this floor holes are formed for putting the plants down through, in order that they may drop under the grinding-wheels. The mills for this purpose have several wheels for grinding the plants, which have less diameters on one side than the other, and are about three feet in width, being constructed with iron bars for

crushing the woad. They are wrought by horses, or any other power, as may be the most convenient. The materials are preserved under the grinding-wheels by proper contrivances, which, as soon as they are sufficiently reduced, force it out of the tracks upon the stone floors on the sides; thus making way for new parcels without the mill being stopped. The bruised woad is then thrown into rooms on the sides of the mill, destined for its reception, by means of shovels. In these it remains till the juice is so much drained off as to leave it in a proper condition for being formed into balls; which is done by labourers, with apparatus for the purpose, and then laid upon trays to be conveyed to the drying ranges, in which they are placed upon grating-shelves that slide on sledges in the drying-houses. These are placed on the sides of galleries, for the convenience of being easily deposited upon them and removed again. It is kept in these till it is sufficiently dried to be laid up in other rooms, until the whole of the crop has undergone the same operations, and the workmen are ready to manufacture it.

It is stated in the Corrected Lincolnshire Report on Agriculture, that to prepare it for use in the art of dyeing, it is necessary for it to take on a proper state of fermentation, which is accomplished in the course of seven or eight weeks, and, in the technical language of the art, is termed *couching*. It is effected by regrinding the balls, in the same mill as before, to a fine powder, and then spreading it upon the floors of the rooms in which the balls were formed, to the thickness of about three feet; where it is then moistened with water, so as to keep it in a proper flow state of fermentation; and so managed by turning that it may pervade the whole in an equal manner. In this business, the direction of an experienced workman is necessary. In the turning, it is of much importance that the parts of the materials be perfectly divided, which can only be effected by a nice management of the shovel: and it is added that much advantage has been found in the goodness of the woad, from the drying and storing of it being performed in a careful manner. When this attention is neglected, the woad will not, on being broken between the finger and thumb, draw out into fine hair-like filaments, or, in the technical language of the manufacturer, *beaver* well; as the use of this substance in the blue vat of the dyer, is not merely to afford the colour of the plant, but, by bringing on a very gentle fermentation, excite the indigo in the same vat to yield its colouring principle more perfectly. This is even necessary for its own colouring-matter being fully imparted. The substance should, therefore, be so prepared in the different operations as to produce this effect in the most certain and perfect manner. When the heat in the process of couching has gone too far, the substance will be what is termed *foxy*; and when it has not proceeded to a sufficient degree, it will be what is called *heavy*. If the material be good, it does not soil the fingers on being rubbed between them; but such as is heavy does. In the conclusion of the process, the cooling is effected in so gradual a manner, as to render it not fit for taking on the same process; and of course proper being preserved in casks, or in any other way. It is then ready for use.

The preparation of woad for dyeing, as practised in France, is minutely described by Astruc, in his Memoirs for a Natural History of Languedoc. The plant puts forth at first five or six upright leaves, about a foot long, and six inches broad: when these hang downwards, and turn yellow, they are fit for gathering: five crops are gathered in one year. The leaves are carried directly to a mill, much resembling the oil or tan-mills, and ground into a smooth paste. If this process was deferred for some time, they

they would putrefy, and send forth an insupportable stench. The paste is laid in heaps, pressed close and smooth, and the blackish crust, which forms on the outside, reunited if it happens to crack: if this was neglected, little worms would be produced in the cracks, and the woad would lose a part of its strength. After lying for fifteen days, the heaps are opened, the crust rubbed and mixed with the inside, and the matter formed into oval balls, which are pressed close and solid in wooden moulds. These are dried upon hurdles: in the sun, they turn black on the outside; in a close place, yellowish, especially if the weather be rainy: the dealers in this commodity prefer the first, though it is said the workmen find no inconsiderable difference betwixt the two. The good balls are distinguished by their being weighty, of an agreeable smell, and when rubbed of a violet colour within. For the use of the dyer, these balls require a farther preparation: they are beat with wooden mallets, on a brick or stone floor, into a gross powder; which is heaped up in the middle of the room to the height of four feet, a space being left for passing round the sides. The powder, moistened with water, ferments, grows hot, and throws out a thick fetid fume. It is shovelled backwards and forwards, and moistened every day for twelve days; after which it is stirred less frequently, without watering, and at length made into a heap for the dyer.

The powder thus prepared gives only brownish tinctures, of different shades, to water, to rectified spirit of wine, to volatile alkaline spirits, and to fixed alkaline lixivium: rubbed on paper, it communicates a green stain. On diluting the powder with boiling water, and after standing some hours in a close vessel, adding about one-twentieth part of its weight of lime newly slacked, digesting in a gentle warmth, and stirring the whole together every three or four hours, a new fermentation begins, a blue froth arises to the surface, and the liquor, though it appears itself of a reddish colour, dyes woollen of a green, which, like the green from indigo, changes in the air to a blue. This is one of the nicest processes in the art of dyeing, and does not well succeed in the way of a small experiment.

Astruc proposes the manufacturing of fresh woad leaves in Europe, after the same manner as the indigo plant is manufactured in America; and thus preparing from it, a blue fecula similar to indigo, which from his own experiments he has found to be practicable. Such a management would doubtless be accompanied with some advantages, though possibly woad so prepared might lose those qualities which now render it, in a large business, preferable on some accounts to indigo, as occasioning greater dispatch when once the vat is ready, and giving out its colour less hastily, so as to be better fitted for dyeing very light shades. Neumann's Chem. by Lewis, p. 437, &c.

The ancient Gauls and Britons used to dye or stain their bodies with this plant, and were probably led from this application of it to use it for dyeing cloth.

Some hold that it was from this plant glass took its denomination; though others derive both *glass* and *glastum* from the British *glafs*, which to this day denotes a blue colour. See GLASS.

A woad blue is a very deep blue, almost black; and is the base of so many sorts of colours, that the dyers have a scale, by which they compose the divers casts or degrees of woad, from the brightest to the deepest.

WOAD, in *Botany*. (See ISATIS.) There are four species.

The broad-leaved woad is cultivated in several parts of

England for the purposes of dyeing, being used as a foundation for many of the dark colours.

Some feed down the leaves of woad in winter with sheep; a practice which Mr. Miller condemns.

Woad grows wild in some parts of France, and on the coasts of the Baltic sea: the wild woad, and that which is cultivated for the use of dyers, appear to be of the same species.

Beside the plant properly signified by the name woad, which dyes a blue colour, we have two others known in our English herbals under that name, as also that of *wold* or *weld*. These are both called by the common people *dyer's weeds*, and are the *luteola* and the *genista tinctoria*.

The ancients confounded all these three plants also under the same names. Paulus Ægineta seems to make them all the same plant; and Neophytus, speaking of the *isatis*, or our woad, properly so called, says, that it was called by the Latins *lutum*. This *lutum* has been by some understood to mean the *luteola*, and by others the *genista tinctoria*; but the latter opinion only is right, for it is described to us by the ancients as having leaves like the *linum*, or flax, and flowers like the broom.

WOAD-Mill and House, that sort of mill and house which is necessary and proper for preparing and fitting this kind of substance for the use of the dyer. The representation of a mill and excellent apparatus for effecting the preparation of the woad plant, which is made use of by Mr. Cartwright, with much success and advantage, in Lincolnshire, may be seen in the second volume of the "General Dictionary of Agriculture and Husbandry."

WOAHOO, or OAHOO, in *Geography*, one of the Sandwich islands; as far as could be judged from the appearance of the north-east and north-west parts, it is much the finest island of the whole group. Nothing can exceed the verdure of the hills, the variety of wood and lawn, and rich cultivated valleys, which the whole face of the country displayed. The road is formed by the north and west extremities. Should the ground-tackling of a ship be weak, and the wind blow strong from the north, to which quarter the road is entirely open, this circumstance might be attended with some danger; but with good cables there would be little risk, as the ground from the anchoring-place, which is opposite to the valley through which the river runs to the north point, is a fine sand. This island is supposed to contain 60,000 inhabitants. N. lat. 21° 43'. E. long. of the anchoring-place 202° 9'. See SANDWICH ISLANDS.

WOALDS, in *Agriculture*, a term not infrequently applied by writers on husbandry to crops of the woad kind. See WOAD.

WOAPO, in *Geography*, one of the Ingraham islands in the Pacific ocean. Captain Ingraham called it Adams. It was afterwards visited by captain Roberts, who named it Jefferson. S. lat. 9° 27'.

WOBBEL, a town of Westphalia, in the county of Lippe; 6 miles E.N.E. of Horn.

WOBURN, or WOBBURN *West*, or *Bishop's Woburn*, a village in the hundred of Delsborough, Buckinghamshire, England, is situated in a narrow valley, at the distance of 3 miles W.S.W. from Beaconsfield, and 26 miles W. by N. from London. The manor of Bishop's Woburn had from time immemorial belonged to the see of Lincoln, till the year 1547, when bishop Holbeach gave it to the crown in exchange. It was granted in 1549 to John, earl of Bedford. In the 17th century it came by marriage to Philip, lord Wharton, whose son and grandson, the celebrated marquis and duke of Wharton, successively held it. After the death of the latter, it was sold to the Berties; from whom it was purchased, in 1784, by Mrs. Dupré, mother

mother of James Duprê, esq. of Wilton-park, who is the present proprietor. The old manor-house was a palace of the bishops of Lincoln, several of whom died here. The marquis and the duke of Wharton are said to have expended incredible sums of money on the house and gardens: of the latter, which in a former age were highly celebrated, scarcely a vestige now remains. The mansion was pulled down in 1750; when one of the wings was fitted up as a dwelling-house, which has since been enlarged and improved, and is now occupied by the countess of Orkney. The parish-church is a spacious and ancient structure, with a nave, two aisles, and a tower. The latter was built about the year 1480, as appears by the epitaph of John Goodwin and Pernell his wife, who are called its founders. In the chancel are several monuments of the families of Bertie and Wharton, among which is one of grey marble to the memory of Philip, lord Wharton, who died in 1695. The font is a curious piece of ancient sculpture. This parish contains 2596 acres, chiefly disposed in arable and wood land. In the population return of the year 1811, the inhabitants were estimated at 1604; the number of houses at 318. An annual fair is held, for which lord Wharton obtained a charter in 1686. A fair was also granted by king Henry VI., but is now discontinued.—*Beauties of England and Wales*, vol. 1. Buckinghamshire. By J. Britton and E. W. Brayley, 1802. *Lycens' Magna Britannia*, vol. 1. Buckinghamshire, 1806.

WOBURN, or *Old Woburn*, a market-town in the hundred of Manshead, and county of Bedford, England, is situated near the western confines of the county, at the distance of 14 miles S.W. by S. from the county-town, and 42 miles N.W. by N. from London. Great part of the town was consumed by fire in 1724, which, though distressing to individuals, proved ultimately beneficial, as the houses were rebuilt in a more convenient and regular manner, with the addition of several good inns, and a market-house. The whole expence of the new buildings was defrayed by the duke of Bedford. The market-house was finished in 1737, but has been materially improved by the late duke Francis. It consists of two floors; the lower fitted up for butchers' shambles, over which is a spacious room for a corn-market. In the population return of the year 1811, the inhabitants of the parish are stated to be 1506, occupying 299 houses. A weekly market is held on Fridays, which was granted in 1242 to the abbot of Woburn, and four fairs annually. The church was erected by Robert Hobbs, the last abbot of Woburn. This structure furnishes a peculiar instance of capricious taste; the body being completely detached from the tower, which stands at about six yards distance. The tower is a small square building, with large buttresses at the corners, and four pinnacles; the church consists of three aisles and a chancel; the whole has recently undergone a thorough repair. Adjoining to the church-yard is a free-school, founded by Francis, earl of Bedford. Here are also alms-houses for twelve poor persons, founded by the Bedford family, and endowed with 50*l.* per annum, which was confirmed by act of parliament in 1761.

About a mile east of the town is Woburn abbey, the seat of the duke of Bedford. This magnificent mansion is situated in the midst of an extensive park, and occupies the four sides of a quadrangle of more than 200 feet. It was erected about the middle of the last century by Flitcroft, for John, the fourth duke of Bedford, of the Russel family, on the site of an old abbey. The original building was founded in the year 1145, by Hugh de Bolebec, for monks of the Cistercian order. In 1234 the monastery was so reduced, that the establishment was for a time broken up,

and the monks dispersed into different convents till their debts were paid. But by various benefactions their revenues were so much improved, that at the general dissolution they were estimated at 391*l.* 18*s.* 2*d.* clear yearly value. The last abbot was hanged for denying the king's supremacy. The site of the abbey was granted in 1547 to John, lord Russel, afterwards earl of Bedford, and has ever since been the principal seat of that noble family. There are no remains of the conventual buildings. The present mansion, originally fitted up in a very costly style, has received many considerable improvements, particularly during the time it was in the possession of the late duke. Mr. Holland, the architect of Drury-lane theatre, has displayed much taste and ability in the additional buildings which have been executed under his direction. The west front is built of the Ionic order, with a rusticated basement. The principal floor, or suite of rooms on this side, consist of a saloon, state bed-rooms, drawing and dining-rooms; the south side contains the library, breakfast, Etruscan, and duke's rooms; the east, the vestibule, servants' offices, &c.; and the north, the French bed-rooms, and various other chambers. Most of the apartments are embellished with fine paintings: the gallery, in particular, exhibits a large and valuable collection of portraits by the old masters. The late duke's favourite pursuits are well known to have been experimental agriculture and breeding of cattle. For this purpose he kept several farms in his own hands. The principal of these, distinguished by the name of the Park-farm, is situated in the park, about half a mile from the house. All ingenious contrivances to shorten labour, and facilitate useful operations, are here concentrated. The farm-yard is replete with conveniences. It contains barns, stables, fatting-houses, &c.; a very complete mill, furnished with a curious machine which threshes and dresses at the same time; a maltern; two pair of stones for grinding wheat and barley; and every requisite for dressing flour, making oatmeal, &c. In another part is a small water-wheel, which gives motion to some very ingenious machinery for bruising malt, and cutting chaff. This farm originated with the late duke, through whose patronage and exertions many improvements have been made in the different branches of husbandry. The present duke follows the steps of his brother in patronising agricultural improvements, and keeps up all the establishments which he formed with a view to that purpose.—*Beauties of England and Wales*, vol. 1. Bedfordshire. By J. Britton and E. W. Brayley, 1801. *Lycens' Magna Britannia*, vol. 1. Bedfordshire, 1806.

WOBURN, a town of the state of Massachusetts, in the county of Middlesex, containing 1277 inhabitants; 15 miles N.W. of Boston.

WOCANELLY, a town of Hindoostan, in Golconda; 40 miles N.W. of Adoni.

WODEN, in *Mythology*. See ODIN.

WODERCUM, in *Geography*. See WORCUM.

WODNANY, or WODNIAN, a town of Bohemia, in the circle of Prachatitz; 12 miles N.E. of Prachatitz. N. lat. 49° 10'. E. long. 14° 2'.

WODWALLA, a town of Sweden, anciently a seaport, but now much reduced, and its privileges removed to Gotheburg, at eight miles distance.

WOEL, a town of France, in the department of the Meuse; 12 miles N.E. of St. Mihiel.

WOELFLIES, a town of Saxony, in the principality of Gotha; 21 miles S.E. of Gotha.

WOERAMATTA, a small island in the East Indian sea. S. lat. 7° 2'. E. long. 131° 36'.

WOERDEN, or WORDEN, a town of Holland, built by

by Godfrey de Rhenen, the twenty-eighth bishop of Utrecht, on the river Rhine, about the year 1160, to keep the citizens of Utrecht in subjection, and maintain his authority. It had a castle, which was formerly supposed to be impregnable; but when the French took the city in 1672, they entirely demolished it, before that time falling to decay. This city had its own particular lords till the year 1296, when Herman de Woerden fortified it, having been convicted of being a party in the murder of Florent V. comte of Holland, who was assassinated by a gentleman named Gerard de Velsen, whose wife he had ravished. It was afterwards sold by Philip II. king of Spain, to Eric, duke of Brunswick; from whom it came, in 1581, under the dominion of the States-General. In 1672, the French having made themselves masters of this place, the Dutch came to besiege it, under the prince of Orange and the comte de Zuytlestein. The comte de Marck, who commanded in the city, began to be much pressed, when the duke of Luxemburg arrived with 9000 men. He passed the morafs by a way which was supposed to be inaccessible, forced the intrenchments, and put the enemy to flight. The Dutch lost 2000 men, killed and wounded, among the former of whom was the comte de Zuytlestein; and the French about 1000; 8 miles W. of Utrecht.

WOGGORA, a small high province of Abyssinia, on the E. of Gondar, which is sown with wheat. This province and Dembea are the granaries of the country.

WOGGT, a river of Austria, which runs into the Ager, near Voglabruck.

WOLYDURGAM, a town of Hindoostan, in Myfore; 15 miles S. of Ousloor.

WOGOW, a town of Prussia; 18 miles S. of Königberg.

WOGSHAID, a town of Austria; 7 miles S.W. of Aigen.

WOHLAU, a town of Silesia, and capital of a principality, on all sides surrounded with marshes, which are a kind of natural defence. It has two suburbs, a Roman Catholic and a Lutheran church. In the year 1640, it was taken by the Swedes; in 1642, surprised by the Imperialists, but soon after retaken by the Swedes; and in 1644, recovered by the Imperialists; 20 miles N.W. of Breslau. N. lat. 51° 20'. E. long. 16° 35'.
